Hythe.—A special meeting of the General Purposes Committee of the Town Council was held last week at which a deputation from the National Electric Construction Co. was received relative to the proposed construction of an electric tramway between Sandgate, Folkestone, and Hythe. The proposal of the company has been before the committee for some time, but the latter's requirements as to widenings, etc., were considered out of proportion to the scheme. Mr. Cownie, joint manager and secretary of the company, who attended on their behalf, said that his company had carefully considered the question of routes, and they came to the conclusion unless they could get a tramway along High-street the scheme would not be worth going in for, so far as Hythe was concerned. Then if they proposed putting tramways down some of their streets, he was afraid they would have very considerable opposition from the ratepayers in High-street, as it was found always that the trade of the town followed tramways, and by taking the tramways through other streets they would be taking a great deal of the trade away from the High-street. They wished, if possible, to get the Council's support. They had got the support of Sandgate, and they had also got the support of Folkestone, so far as the committee were concerned. The company were prepared to pay to the Council the sum of £2,000, so that they could do whatever widenings they liked. The company, said Mr. Cownie, would also be prepared to pay £1,500 to the Council for all the widenings they had already done. The maximum fare would be 1d. a mile, but for a through fare it would be less. We understand that the Council will further consider the matter when plans have been deposited. It had been moved and seconded previous to the arrival of the deputation, that the Council at the present time do not give their consent, reserving to themselves the right to act after the plans have been deposited in accordance with the standing orders.

London County Council.—At Tuesday's weekly meeting of the Council, the Highways Committee reported that their attention had been called to the fact that there appeared to exist no direct authority to make by-laws regulating the use of the tramway subway from the Victoria-embankment to Southampton-row authorised by the London County Council's Act. They recommended, and it was agreed, that authority should be sought in the next session of Parliament to enable the Council to make the necessary by-laws. In respect of the Council's application for the compulsory acquisition of Holloway car-shed site, the Highways Committee recommend that powers be sought for the purchase of a further site with an area of about 3¾ acres in Pemberton-road for the erection of a car-shed and sub-station in connection with the electric working of the northern section tramways. In consequence of the unsatisfactory conditions of the lines, and the impracticability of working them at all remuneratively, it is proposed that the tramways which have been transferred to the Council from the London, Camberwell, and Dulwich Tramways Co. be abandoned. It is also recommended, with a view to preventing overlapping, that, in lieu of the existing ½d. fares upon the Greenwich route of the Council's tramways, ½d. fares be charged for journeys between the undermentioned points: (1) Blackfriars Bridge and Elephant and Castle; (2) Westminster Bridge and Elephant and Castle; (3) Waterloo Bridge and Elephant and Castle; (4) Elephant and Castle and Tower Bridge-road; (5) Tower Bridge-road and Dun Cow, Old Kent-road; (6) Dun Cow and Canal Bridge, Old Kent-road; (7) Canal Bridge and Old Kent-road railway station; (8) Old Kent-road railway station and New Cross-gate; (9) New Cross-gate and Marquis of Granby; (10) Marquis of Granby and High-street, Deptford; (11) High-street, Deptford, and Devonshire-road; (12) Devonshire-road and King William-street; (13) King William-street and the present terminus at Greenwich.

LIGHTING AND GENERAL.

Colwyn Bay.—It is proposed to borrow £10,000 for electric lighting purposes.

Barnsley.—Sanction has been obtained to borrow £2400 for public lighting at Worsborough.

Woolwich.—The Borough Council intend to support the London County Council's Wiring Bill.

St. Pancras.—The Borough Council have decided to support the London County Council's Wiring Bill.

Derby.—On account of the Royal Show, London-road will be lighted by arc lamps as far as the showground.

Gravesend.—Application is to be made for a loan of £7,000 for extension of plant at the electricity station.

Stourbridge.—The Council are dealing with an electric power company in regard to the execution of their provisional order.

Weardale.—The Council are approaching the Stanner Steelworks with a view to lighting the district by electricity from the company's plant.

Liversedge.—The Urban District Council have confirmed a previous resolution that borrowing powers should be applied for for £1,500 for electric supply purposes.

Hendon.—The Rural District Council are corresponding with the Northwood Electric Power Co. *re* their application for supplying electric light for the district.

Ebbw Vale.—Operations have actually commenced for the supply of electricity for public lighting, and will probably be completed before the end of the present winter.

Swansea Telephones.—We understand that the Corporation have just completed the connecting-up for intercommunication between the municipal and National services.

Wandsworth.—A notice from the County of London Electric Supply Co. of intention to lay electrical conduits in South-street, Wandsworth, has been approved.

Trowbridge.—The Urban District Council have decided to charge the National Telephone Co. 1s. per pole for 35 poles to be erected in Bradley-road for telephonic purposes.

Stockton.—The Rural District Council are applying for an extension of the time in which to carry out the provisions of the electric lighting order received some years ago.

Ramsgate.—St. Mary's Church is the first place of worship in the town to be electrically lighted. The installation has been carried out by the Ramsgate and District Electricity Supply Co.

Llangollen.—The agreement drawn up in accordance with the tender accepted by the Council for the lighting of the entire urban area by the Llangollen Electric Lighting Co. is ready for sealing.

Montrose.—An electrical exhibition is being held in the Burgh Hall, Montrose, by the North of Scotland Electric Light and Power Co., under the direction of the company's manager, Mr. Harold Hale.

Calcutta Tramways Co.—An interim dividend of 3s. 6d. per share on the old shares (being at the rate of 7 per cent. per annum, free of tax), on account of the profits for the half-year ended June 30, is announced.

Holyhead.—The Urban District Council have arrived at a settlement with the National Electric Construction Co. in regard to an amount of £609 claimed under which the company receives £256, plus £30 for lamp fittings.

Agency.—Messrs. Bray, Markham, and Reiss have appointed Messrs. J. Parkinson and Co., St. Nicholas-buildings, Newcastle-on-Tyne, their sole agents for Northumberland, Durham, and the Cleveland district of Yorkshire.

Calcutta Electric Supply Corporation.—The number of units delivered to consumers during the four weeks ending Oct. 27, 1905, were 358,193, compared with 288,297 units in the corresponding four weeks of the preceding year.

London Gazette.—The first meeting in the estate of Harry Jones and Gwilt Lloyd Cathrall, plumbers and electrical engineers, Chester-street, Wrexham, will be held at Crypt-chambers, Eastgate-row, Chester, at 12 noon on Nov. 29.

British Aluminium Co.—The directors of the British Aluminium Co. have decided to pay an interim dividend for the half-year ended June 30 last at the rate of 6 per cent. on the "A" preference shares, and 7 per cent. on the 7 per cent. preference shares.

Kensington.—An application from the Notting Hill Electric Lighting Co. relative to proposed extensions of their mains in Latimer-road and Boundary-road, and three out of five applications received from the Post Office for permission to lay pipes for telephone wires, etc., have been agreed to.

Taunton.—The recent temporary failure of the electric light was caused by the breakdown of a couple of pipes connected with one of

Digitized by Google

the boilers at the Corporation works. The damage was put right during the night. The new boiler which will soon be installed at the works will prevent a similar occurrence.

Ipswich Engineering Society.—At the last meeting of the Ipswich Engineering Society the newly-elected president. Mr. Frank Ayton, chief engineer of the Corporation electric works, delivered an address upon the subject of "Present-Day Features in the Generation, Distribution, and Utilisation of Electric Power."

London County Council.—On Tuesday it was agreed to lend the Battersea Borough Council £9,218 for street lighting purposes and the Fulham Borough Council £25,000 for electric light installation. Sanction was also given to the borrowing by the borough of Stoke Newington of £6,715 for electric light installation and meters.

Erith.—The Works Committee, after discussing with the surveyor and the electrical engineer the question of the rearrangement of the lamps along the tramway routes, have asked these two officials to submit a joint report upon the subject, with plan showing the position of present lamps, the tramway poles, and proposed scheme of rearrangement.

Woodford.—Out of 3,646 circulars sent out to obtain the opinion of the ratepayers as to the advisability of applying for a provisional order under the Electric Lighting Acts 1,554 replies have been received, and of these 456 answered "Yes," 1,052 answered "No," and 36 were irregular. Consequently the application for a provisional order will not be proceeded with.

Chelmsford.—After a very severe fight with the local gas company the Chelmsford Electric Light Co. have obtained the street-lighting contract for a number of years. The 300 half-ampere A type Nernst lamps to be used are being supplied by the A.E.G. English Manufacturing Co., who hold the Nernst lamp patents for Great Britain, all British Colonies, Asia, Africa, South and Central America.

Indian and Colonial Trade Inquiry Offices in the City.—The India Trade Inquiry Office, at 73, Basinghall-street, London, E.C., has been established for the purpose of supplying the general public with all available information as the commercial products, manufactures, and trades of British India. The Canadian, Cape of Good Hope, and Queensland Governments have opened offices in the same building.

Edmonton.—The District Council have received a letter from the Board of Trade asking why no steps have been taken to carry out the obligations of the Council under their provisional order, and for reasons why the order should not be determined. The Council has directed a reply to be sent asking for an extension of time until the agreement with the North Metropolitan Electric Supply Co. was completed, and explaining the facts.

Bury.—The District Chamber of Commerce recently discussed a complaint made by the Bury Manufacturing Co. with regard to the charge for trunk calls to Bradford, urging that Bury was at a disadvantage, and asking the chamber to take up the matter. It was also mentioned that the charge for calls from Whitefield to Bury was 6d. It was resolved that strong recommendations be made to the National Telephone Co. asking them to provide a remedy.

Lowering Gear.—We are informed by the London Electric Firm, George-street, Croydon, that their "one working part" arc lamp lowering gear is meeting with considerable favour by reason of its unique and practical design and construction, and that although it has only been on the market a very short time it has been supplied to two Government departments, 16 corporations and supply companies, several railways, and a large number of contractors, including a single order for 50 complete sets.

Dorking.—The Urban District Council's Electricity Committee have received a letter from Mr. Trentham, enclosing one from Messrs. Edmundsons, further pressing for the Council to reconsider and sanction the laying down of the cable necessary for the Deepdene supply, and expressing their willingness to relieve the Council from all liability and risk in the matter pending the approval of the Local Government Board being obtained to the loan. We understand that the Council have declined to alter their previous decision.

Telephone Extensions.—The Association of Chambers of Commerce has been informed by Lord Stanley that at present it does not seem possible for him to hold out hopes of any material extension of existing facilities for telephonic communication with the Continent, but he fully appreciates its importance to the mercantile community. The extensions which have been possible during recent years are detailed, and Lord Stanley adds that the communication between Liverpool and Antwerp, and between this country and Holland, has been found to be impracticable.

New Issues.—A prospectus has been issued by the Newquay Electric Light and Power Co. Capital, £15,000 in £1 shares. Secretary: E. Ernest Smith, 66, Victoria-street, Westminster. The object is to take over and work the parliamentary powers granted in 1904 to Messrs. Foote and Milne for the supply of electricity for public and private purposes with the Newquay Urban District Council's area. The construction of the works will be undertaken by Messrs. Foote and Milne. Letters of allotment and regret have been posted in connection with the issue of £150,000 4½ debenture stock of W. T. Henley's Telegraph Works Co.

Dunkeld.—A hitch has occurred in the telephonic arrangements. Work had been begun consequent upon an agreement between subscribers and the Postal Department for the establishing of a telephonic district which included Pitlochry. A number of the signatories, however, belong to Birnam, and the Department having announced that this part can only be included on payment of an additional amount, an indignation meeting was held last week, at which it was decided that the whole of the subscribers renounce the agreement if the Department do not give way. The resolution has been sent to the secretary of the Department for further consideration.

Bermondsey.—The electrical engineer has reported on the ventilation of the Council chamber, and we understand that the following estimate for the work has been adopted: fan and motor, with starters, £41; galvanised sheet-steel duct house and labour, £55—£96. The Electric Lighting Committee report new consumers equal to 468 8-c.p. lamps, and state that the number of lamps connected to the mains are now 52 421 lamps for private consumers and the equivalent of 4 646 lamps for public lighting, a total of 57,067 lamps. The highest load observed this year was 575 kw., as against 437 kw. for the corresponding period last year, an increase of 32.

Beckenham.—The clerk is taking steps to open the necessary accounts on the Council taking over the management of the electric lighting works, and in future the dust destructor and electric lighting works will be treated as separate undertakings. For the present the destructor is to be credited with £143 per annum, the estimated value of the steam supplied by the destructor and used for the generation of electricity, and the electric lighting account debited with £150 per annum, the amount hitherto charged to the British Insulated and Helsby Cables in respect of the cost of collecting the electric lighting charges and of clerical work and book-keeping performed in respect of the undertaking.

Stock Exchange.—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to British Aluminium Co.'s 30,000 ordinary shares of £5 each, £2 paid, and £300,000 5½ per cent. Loch Leven debentures of £100 each. The committee have ordered the undermentioned securities to be quoted in the official list: Adelaide Electric Supply Co.'s 10,000 6 per cent. cumulative preference shares of £5 each (fully paid), Nos. 1 to 10,000; Amazon Telegraph Co.'s further issue of £35,900 5 per cent. debentures of £100 each, Nos. 1,251 to 1,609; and Anglo-Portuguese Telephone Co.'s £50,000 5 per cent. first mortgage debenture stock.

Elgin.—The Town Council have received a report by Messrs. Buchan and Hogarth, Edinburgh, on the proposed electric lighting scheme in combination with a refuse destructor. The engineers considered they would obtain 4,500 lamp connections, and recommended the adoption of the low-tension three-wire system, with a continuous current, and 230-volt lamps. The estimate of the capital expenditure at the end of the first year is £16,200, and at the end of the fourth year £17 300. The engineers estimate that the revenue from the first year's working of the scheme would have a loss, due to the heavy capital charges, of £273 but that at the end of the fourth year there would be a profit of £342, which would go against the losses of the first year or two. The report is being printed and distributed amongst the members of the Town Council.

Electricity Shares.—The electric share market has not displayed much activity during the past week, the *Financial Times* says, the tone has continued dull, and the majority of changes in prices are in a downward direction. Supply descriptions in particular have been weak, though the declines are not of serious extent as a rule. St. James's and Pall Mall ordinary and preference have each receded ¼ to respectively 13¼ and 8¼. Kensington and Knightsbridge at 11½, London preference at 5, Charing Cross at 7, and County of Londons at 10 have fallen ¼ while Westminsters have declined ⅛ to 12½. Chelseas, however, have improved ¼ to 6⅛. Among manufacturing descriptions India Rubbers have risen ⅛ to 16½, and Electric Construction preference ⅛ to 2¼, but Telegraph Constructions have relapsed 1½ to 33, and British Westinghouse preference have dwindled 1/16 to 2⅞. In the traction division, Bath Electric Trams have been in demand, the ordinary having risen 1s. 6d. to 19s. 6d., and the preference 6d. to 20s. 6d. Anglo-Argentine Trams have hardened 1/16 to 8 13/16, but Buenos Ayres and Belgranos have fallen ¼ to 2⅞.

Victoria Falls Power Scheme.—The Duke of Abercorn, K.G., who presided at the last meeting of the British South Africa Co., referring to what he called the great project of the African Concessions Syndicate to transmit power from the falls to the Witwatersrand Mines, said he was informed that the highest engineering authority had been obtained in support of the immediate realisation of this enterprise, and, though it would be premature for him to say much more upon the point, he understood that negotiations for the sale of power were already proceeding, and that there was good hope of success. If so, the company, as the owner of half the capital of the Concession Syndicate, and of a reserved interest in profits, would have an important direct interest, and would also reap the indirect results which may be expected to flow from the carrying out of such an enterprise in the heart of Rhodesia. The Special Commissioner of *South Africa*, telegraphing from Cape Town on Nov. 21, says: "I have just had an interview with Sir Charles Metcalfe, who is returning to England by way of the east coast. He tells me he has discussed the great scheme for the transmission of electric power from the Victoria Falls to Johannesburg with a number of leading Rand men, who are convinced that the scheme is perfectly feasible. The Rand mining houses will probably conclude contracts which will have the effect of reducing the cost of their motive power by half, with a saving of at least two million pounds annually."

York.—The city treasurer, Mr. James W. Davison, has just issued his abstract of the municipal accounts for the year ending March 31, 1905. The electricity works have cost so far £124,490, the whole of which is laid out in buildings, plant, machinery, cables, etc. The year ended with a deficit of £2,946, which was transferred to a specially created suspense account, and which it is hoped to clear off in the near future. The revenue account shows that the expenditure for the year was £6 842; the generation of electricity costing £3,615; the distribution, £240; public lamps (wages and repairs), £617; rents, rates, and taxes, £453; management expenses, £923. By the sale of electricity £9,968 was realised, and the total revenue was £10,732. There was consequently a profit on the year's working of £3,890, but this was

Digitized by Google

insufficient to meet the year's charges on interest and sinking fund, hence the necessity for a suspense account. During the 12 months the output totalled 1,114,692 units, of which 770,889 were sold to private consumers, and 133,111 used for public lighting.

Cheap Electricity.—Under the title of "Cheap Electricity for Power, Lighting, Heating, and Ventilating," the South Metropolitan Electric Light and Power Co., 37, Tranquil-vale, Blackheath, S.E., have issued a pamphlet, in which there is a map showing that their area of supply extends from the River Thames on the north to Anerley and Croydon on the south, and from Woolwich on the east to Lambeth and Camberwell on the west. In addition, the company may supply in bulk at the boundary line to undertakers (local authorities, companies, or persons) authorised to supply electrical energy for (1) tramways, partly within and partly without the company's area of supply, and (2) for other purposes. Among such authorised undertakers are the London Electric Supply Corporation, South London Electric Supply Corporation, County of London Electric Supply Co., Kent Electric Power Co., Bromley (Kent) Electric Light and Power Co., Croydon Borough Council, Beckenham Urban District Council, metropolitan borough of Woolwich, Poplar metropolitan borough, and the Charing Cross and Strand Electricity Supply Corporation.

Radcliffe.—The Electricity and Tramways Committee have been discussing letters from the British Aluminium Co., requesting the Council to authorise the Lancashire Electric Power Co. to furnish them with a supply of electricity for power purposes at their proposed works in Mount Sion-road, and from Messrs. A. and J. Gilbert and Co., who stated that if the Council are unable to supply electricity to their works for power purposes, the Lancashire Electric Power Co. were willing to do so if authorised. They have decided to ask the Lancashire Electric Power Co. to furnish a standard tariff, based on a sliding scale, at which they were prepared to supply power consumers in the district, the tariff to be in such form that it shall definitely apply to any power consumer irrespective of his position in the district, and that they be also requested to state the rate or amount of commission the company would be prepared to allow this Council in respect of the aforesaid supply, the committee being of opinion that a payment by way of consideration should be made by their company to the Council if arrangements were made with respect to the supply of electricity to the proposed works of the British Aluminium Co.

Stepney.—An extension of mains is to be carried out in Tenter-street, and an application from the secretary of the General Post Office, on behalf of the Postmaster-General, for the Council's permission to the placing of an underground telegraphic line along east and north sides of Glamis-road and Shadwell High-street from a point between Cable-street and Juniper-row to Love-lane, also along west side of King David-lane from Short-street to High-street, also to the building of boxes as required, has been agreed to. With regard to the charges for current, it is proposed that the charge for lighting, as and from June 1 next, at the rate of 8d. per unit for the first 30 hours' use of the maximum demand during each of the six months ending March, and for the first 20 hours' use during each of the six months ending September, and 1d. per unit for all further consumption in each month, any resolution or other act of the Council or their predecessors to the contrary notwithstanding, be, as and from Oct. 1, 1905, modified to the following extent: (*a*) that to any consumer whose total accounts, calculated on the undermentioned rates for any half-year ending June 30 and Dec. 31, reach £60 or over, or who is willing to guarantee this amount as a minimum payment for each such period, the charge for current for lighting purposes shall be 6d. per unit for the first 30 hours' use of the maximum demand during each of the six months ending March, and for the first 20 hours' use during each of the six months ending September, and 9d. per unit for all further consumption in each month; and (*b*) that in calculating the total amount of a consumer's half-yearly bill for the purpose of arriving at the minimum mentioned in (*a*), the accounts for lighting, power, and other purposes on the same or different premises be added together. Provided that where the accounts of various premises are so added together the average half-yearly account per service shall not be less than £15.

Dundee.—Mr. H. Richardson, the engineer, submitted to a meeting of Dundee Electrical Committee on Monday a report stating that the business of the department had grown to such an extent that the necessity of extra generating plant and feeder cables must be settled immediately, and could no longer be delayed. He pointed out that the district of Lochee had never yet been supplied with electricity, although in several directions it was required there. Apart from that, the load in the districts being worked was such as to give the present station and cables as much work as they could do; in fact, the cables to the West Park, northern, and Maryfield districts were overloaded to an extent which made it impossible to keep up a good pressure of supply through the winter. He estimated that to extend cables and machinery on the same low-pressure system in conformity with the present plant and system would cost as nearly as possible £35,000. This would enable the department to meet the extra work for lighting and power for the next two or three years, but the copper cables thus laid underground were, owing to the low pressure of supply system, far too expensive for the power they carried to these districts. The alternative was to put down a new power station on the high-pressure system of supply with the intention of driving little sub stations from it in each of the outlying districts—to begin with, say, two sub-stations, one at West Park and one at Maryfield—and adding others as required. This scheme would give the department a more elastic limit to its resources for the supply of electricity. It would also give an unequalled facility for the supply of cheap power for the development of all industries, because from such a station they would then be able to cope with it on a big scale, and with some possibility of commercial success. The cost of beginning such a station with two sub-stations would not be less than £75,000, exclusive of the land. It was, therefore, important that this matter should be faced and settled immediately, because the business of the department would not admit of any more delay in the plan of extending the present station or of forming the nucleus of a large station, which must be working by next winter. In these circumstances the engineer asked that he be given instructions to prepare specifications and to ask for tenders for (1) the installation of a new system and new power station, or (2) the extension of plant in the present generating station. After discussion it was decided, having regard to the great importance of the matter, to defer consideration for a month.

Fulham.—At Wednesday's meeting, the report of the Law and Parliamentary Committee was submitted with regard to the award of the arbitrator (Mr. James Swinburne) on the Council's claim for damages against the National Electric Construction Co. in respect of two fatal accidents at the public baths on Dec. 23, 1902. The arbitrator, after stating the steps in the proceedings, found as follows: "I find as a fact that the accident which occasioned the deaths was caused by the fact that certain iron pipes forming part of the installation supplied by the contractors under the said contract were not earthed—that is to say, were not electrically connected to earth. If the said pipes had been earthed, the accident would not have happened. The omission to earth the said pipes was a matter of design and not a matter of materials or workmanship, and was patent to any electrical engineer inspecting the installation. Apart from the reference to the rules of the Phœnix Fire Office above referred to, no indication was given on behalf of the Council to the contractors by drawings, specification, or otherwise that they were required to earth the pipes. Having regard to the state of knowledge among electrical engineers at the time of the contract and of the execution of the works, I have come to the conclusion that the omission to earth the pipes under all the circumstances of the case did not indicate a want of reasonable care or skill on the part of the persons responsible for the omission. Assuming that the contractors were responsible for the omissions, I find, as a fact, that they were not guilty of want of reasonable care or skill in omitting to earth the said pipes. It was admitted before me that, so far as this arbitration is concerned, the Council did not rely on any defects in the installation other than the omission to earth the said pipes. With regard to the rule of the Phœnix Fire Office above referred to, I find as a fact that in the case of the said pipes earthing would not have been desirable so far as risk of fire is concerned. It would, in fact, have been desirable so far as risk of accidents to bathers is concerned. The buildings and the electrical installation were inspected and passed in April, 1902, by the surveyor of the Fine Art and General Insurance Co., who were the fire office concerned in the risk. I find that the Council have expended the sum of £1,173. 13s. 1d. in respect of the matters in dispute in this arbitration, and that if they are entitled to recover against the contractors in this arbitration by way either of indemnity or of damages, that is the sum which they are entitled so to recover. The question for the opinion of the court is whether upon the facts herein stated the Council are entitled to recover the said sum of £1,173 13s. 1d. from the contractors in this arbitration. If the court answer the above question in the affirmative, then I find and award that the Council are entitled to recover from the contractors the said sum of £1 173. 13s. 1d., and I award and direct that the contractors do pay to the Council their costs of the reference and also the costs of this my award. If the court answer the above question in the negative, then I find and award that the Council are not entitled to recover anything against the contractors, and I award and direct that the Council do pay the contractors their costs of the reference and also the costs of this my award." The award has been stated in the form of a special case for the opinion of the court, and the Law and Parliamentary Committee have been advised by counsel that they ought to argue before the court the points of law reserved. The case has been set down by the contractors for hearing before one judge of the King's Bench Division, and the committee have given the town clerk instructions to brief counsel. The borough electrical engineer submitted the following statistics: House refuse—previously reported, 1905 6, 17,951 tons (1904 5 16 696); from Oct. 20 to Nov. 9, 1905 2 091 tons (1,839)—total, 20 045 tons (18,585). Trade refuse—previously reported, 375 tons (377); from Oct. 20 to Nov. 9 1905. 45 tons (36)—total, 420 tons (413). Clinker—previously reported, 4,890 tons (4,184); from Oct. 20 to Nov. 9, 1905, 439 tons (480)—total, 5 320 tons (4 664). Connections previously reported 1 631, 80,729 8-c.p. (1 304, 61,448); from Oct. 20 to Nov. 9, 1905, 29, 2,310 8-c.p. (22, 1,802)—total, 1,660, 83,039 8-c.p. (1,326, 63,250). Consumers not yet ready for connection, 3; consumers not yet paid deposits 3. A transformer station is to be erected and fitted with two 30-kw. transformers, and cables are to be extended at a total cost of £353.

PROVISIONAL PATENTS, 1905.

Nov. 13.

23241. Improvements in laying electric conductors. John Henry Chilcote Brooking, 85, Northumberland-road, Old Trafford, Manchester.

23267. Momentum engine and electrical self-generation dynamo and motors. Benjamin Charles Pole, 19, Imperial-buildings, Ludgate-circus, London.

23298. Improvements in and relating to electrical safety devices for guarding against burglary and the like. Carl Jacob, Thanet House, Temple Bar, London. (Complete specification.)

23312. Improvements in connection with the electro-deposition of copper and other metals. Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

Digitized by Google

23313. Improvements in removing metallic cylinders from mandrels on which they are electro-deposited. Sherard Osborne Cowper-Coles, 4, South-street, Finbury, London.

23320. Improvements relating to sockets for receiving electric lamps, plugs and the like. Frederick Millington and Albert Hugh Miller, 322, High Holborn, London.

Nov. 14.

23328. Improvements in electrical conduit tubing joints. Alexander Harold Hoar, 32, Barnsdale-road, Harrow-road, London.

23379. Improvements relating to pendants or like supports for electric lamps. Hubert Chippendale Smith, 18, Southampton-buildings, Chancery-lane, London.

23402. Improvements in electric furnaces. Paul Girod, 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 24, 1904, being date of application in France.) (Complete specification).

Nov. 15.

23437. Improvements in and relating to incandescent electric lamps. The British Thomson-Houston Company, Limited. 83, Cannon-street, London. (The General Electric Company, United States.)

23438. Improvements in and relating to electric distribution systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23439. Improvements in and in the manufacture of heat radiators. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23440. Improvements in and relating to electric distribution systems. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23441. Improvements in and relating to electric railways. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23442. Improvements in and relating to methods of manufacturing incandescent electric lamps. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23446. Divers' and miners' portable and electrical lamp. William Dentith and Harry Midgley, 30, Baillie street, Rochdale, Lancs.

23447. Improved electrical lamp for photographing in the dark. William Dentith and Harry Midgley, 30, Baillie-street, Rochdale, Lancs.

23449. Electric working of mine shafts. James Swinburne, 82, Victoria-street, Westminster, London.

23451. A combined electric and automatic self-locking double railway carriage lock and spindle adaptable, final fastener unpickable and burglar-proof. Henry Taylor, 238, Wednesbury-road, Pleck, Walsall.

23474. Improvements in and relating to the electro-deposition of metals, alloys, and the like. Mary Kezia Dooley Roberts and Edward Woodriff Jaffray, 2, Church-gate, Nottingham.

23507. An instrument for demonstrating the kinetic energy of the α-rays emitted by radium and other radioactive bodies. Charles William Raffety, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

23526. Improvements relating to electrical furnaces Benvenuto Platschick, 7, Southampton-buildings, Chancery-lane, London.

Nov. 16.

23547. An improved method of fixing the grooved casing covers as used for the wires in electric lighting. William Mills and Frank Tobias Paine, High-lane, Marple, Cheshire.

23553. Improvements in electric motors and similar dynamo-electric machines. Veritys Limited and Paul Arthur Hirsch, 11, Burlington-chambers, New-street, Birmingham.

23561. Improvements in electricity meter meters. George Hookham, 18, Southampton-buildings, Chancery-lane, London.

23569. Improvements in electric accumulators. Ernest Bailey, William Plews, and Thomas Wade Anderson, 5, York-place, Leeds.

23582. Improvements in electrical switches. William McGeoch and Co., Limited, and Walter Leonard Barber, 35, Temple-row, Birmingham.

23584. Improvements in electric motor apparatus applicable to machinery of all kinds requiring force. Thomas James Howell and Edwin Joseph Richardson, 41, Brook-street, Grosvenor-square, London.

23595. Improvements relating to electric railways and tramways on a road-contact system. Gustav Paul, 37, Essex-street, Strand, London.

23624. Improvements in electric circuit breakers. The Felten und Guilleaume-Lahmeyer-werke Akt.-Ges., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Dec. 22, 1904, being date of application in Germany.) (Complete specification.)

Nov. 17.

23656. Improved top electric roller for electric stop-motion frames. Arthur Broadbent, 69, Maud-street, Rochdale.

23661. Improved arrangement for the regulation of speed of compensated single-phase motors. Engelbert Arnold and Jens Lassen La Cour, 34, Castle-street, Liverpool. (Date applied for under Patents Act, 1901, Nov. 21, 1904, being date of application in Germany.) (Complete specification.)

23662. An expanding terminal connection for electric cables and the like. Claude Harold Robinson, Carlton House, Pontypool, Monmouthshire.

23710. Improvements in and relating to transformers and the like. Arnaldo Paolo Zani, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

23722. Improvements in and relating to systems of connections for telephone offices with separated plug service and means for signalling whether an operator is unoccupied or engaged. Deutsche Telephonwerke R. Stock und Co., G. m. b. H., Thanet House, Temple Bar, London. (Date applied for under Patents Act, 1901, Nov. 17, 1904, being date of application in Germany.) (Complete specification.)

23728. Improvements in or relating to shade holders for incandescent electric lamps. Henry Simmonds, 7, Southampton-buildings, Chancery-lane, London.

23738. Improvements in or relating to commutators and the like. Henry Alexander Mavor and Mavor and Coulson, Limited, 46, Lincoln's-inn-fields, London.

23751. Improvements in brush contacts for electric switches. William Harding Scott, 47, Lincoln's-inn-fields, London.

23753. Improvements in electrical apparatus for regulating clocks. Robert James Rudd, 40, Chancery-lane, London.

Nov. 18.

23756. A new or improved junction box for electric cables. Edward Wilmer Hill, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

23803. Improvements in or relating to electrically-propelled vehicles. Carl Tunstill John Oppermann, 53, Chancery-lane, London.

23838. Improvements in and relating to apparatus for changing the frequency of alternating electric currents. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

23839. Improvements in dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London.) (The General Electric Company, United States.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 7.

1904.

24573. Dynamo-electric machines. Batchelder. (Date applied for under International Convention, Nov. 12, 1903.)

24689. Electric storage batteries. Roselle. (Date applied for under International Convention, Nov. 16, 1903.)

24701. Electric motor control systems and apparatus therefor. British Thomson-Houston Company, Limited. (General Electric Company.)

24769. Electrical commutators. Nalder Bros. and Thompson, Limited, Nalder and Cox.

25010. Process for producing nitric acid by aid of electricity. William Phillips Thompson (Westdeutsche Thomasphosphat-Werke G. m. b. H.). (Rights under Patents, etc., Act, 1901, not granted.)

26175. Electric transformers British Thomson-Houston Company, Limited. (General Electric Company.)

26292. Joints between metal and vitreous materials and method of forming the same. British Thomson-Houston Company, Limited. (General Electric Company.)

28157. Actuating apparatus for magneto-electric spark ignition apparatus and the like. Unterberg.

28336. Brush-holders for dynamo-electric and like machines Veritys Limited and Rogers.

29015. Automatic control of electric circuits under overload. Siemens Bros. and Co., Limited, and Ledger.

29337. Method and means for the protection of electrical apparatus branched on circuits which are traversed (accidentally or otherwise) by currents of high frequency. Gaiffe.

29627. Electrical fire-alarm or other call apparatus. Shore and Heap.

1905.

2015. Brush-holders for electric dynamos or motors. Barker and Burleigh.

2545. Electrical regulation of clocks. Chandler and Bonniksen.

2850. Electrostatic watt and watt-hour meters. Wilson and Wilson.

4127. Automatic electric warning signals for railways and the like. Hollyer.

Digitized by Google

3183. Automatic regulating apparatus for electrical installations with variable current consumption, worked by dynamos and accumulator batteries. Dick.

3664. Prepayment attachments for electricity meters Swan.

4233. Electric ignition devices for internal-combustion engines. Millington and Miller.

4379. Supply and regulation of the electric energy employed in the operation of arc lamps used in search-lights and like apparatus. British Thomson-Houston Company, Limited. (General Electric Company.)

6774. Towers or standards for supporting electric lamps Coverstone.

4848. Arc lamps. Justice. (Phönix Elektrotechnische G. m. b. H.)

5205. Trolleys for electric tramcars and the like. Bradley and Mason.

7068. Safety electric circuit closers Ottinger.

7620. Apparatus for the measurement of X-rays and other similar radiations. Gaiffe.

8614. Appliances for lighting gas lamps and the like by electricity. Thompson. (Freudenthal.)

10480. Night-sights with electric incandescent lamps for artillery sighting or for any instrument in which night sighting may be required. Bertalot. (Bouiau.)

10978. Telautograph apparatus. Brenner and Isaac. (Date applied for under International Convention, May 25, 1904.)

13588. Commutators of dynamo-electric machines Siemens Bros. and Co., Limited, and Berry.

13589. Method of and apparatus for cooling commutators of dynamo-electric machines. Siemens Bros. and Co., Limited, and Berry.

15290. Transportable telephone apparatus. Jacobsen. (Date applied for under International Convention, Dec. 16, 1904.)

17398. Telephone or like transmitters. Cutmore and Telaupad Syndicate, Limited.

NOTES.

Northampton Institute Engineering Society.—A meeting will be held this evening at 7.30 p.m, when a paper will be read by Mr. W. Chappell on "Water-Turbines as Applied to the Generation of Electricity." Dr. R. Mullineux Walmsley will take the chair.

Electrical Manufacturers' Association.—We have received from Mr. Walter Davenport (the secretary) an intimation that at a recent meeting of the members of this association it was unanimously decided that, owing to the enormous increase in the number of applications, they must reluctantly discontinue the practice of subscribing to annual beanfeasts, Christmas boxes, new year gifts, etc. In consequence thereof, the members of the above association have unanimously agreed to discontinue this custom.

Electrical Exhibition.—We are officially informed that the financial affairs of the recent exhibition are now so far advanced as to enable the management to announce that the exhibitors will receive a rebate of 25 per cent. upon the sums paid by them for space, while a very considerable sum will be available for benevolence. The fact that the exhibition was an unqualified success from every point of view is satisfactory not only to the executive committee, but to the exhibitors and the trade generally. No small measure of its success is due to the excellent organisation, and the executive committee, together with the secretary (Mr. Walter Davenport), deserve to be specially congratulated upon the result. It remains to be seen how far this decision will apply to those who receive unsolicited Christmas presents from manufacturers.

Turbines.—The Cunard liner "Carmania," which, in place of reciprocating engines, is equipped with the most powerful installation of model turbines yet conceived, set out upon her maiden voyage last Tuesday week. She had been previously subjected to a six hours' trial run from Glasgow, in which she attained an average speed of 19½ knots with what, in the estimation of her builders and designers of the turbines, proved to be a satisfactory consumption of fuel. It is interesting to note the fact that on her trial trip she carried, among an influential company, special representatives of the Russian and Japanese navies, the former of whom (Major-General Poretchkin) is now in this country for the purpose of studying the problems suggested by the arrival of the turbine with a view to its adoption in the new war fleet which the Tsar is about to build.

Copper Wire.—In the discussion on Mr. Fowle's paper on railway telephone service read at the recent conference of the Association of Railway Telegraph Superintendents some interesting facts were brought to light concerning the life of copper wires. It was stated by one speaker that the copper wires laid along the Wabash Railroad had been in use for 15 to 18 years without any signs of deterioration being shown. Another speaker remarked that copper wire on a certain point on the Erie Railroad, in close proximity to a chemical works, served about 3½ years, while an example was shown of a case in Texas where 20 miles of copper wire in the Beaumont oil region had been badly impaired in two years by the sulphurous atmosphere. The iron wire in the same region was eaten up in about one year. In Beaumont lead-covered cable is used with good results, the lead apparently acting as a protection against the sulphur fumes. A test of aluminium wire on the Erie road was made at the point above mentioned. It worked well for about six months, when one day a circuit was broken, and investigation showed that three sections of the wire had "evaporated."

Electric Traction.—Engineers are beginning to perceive that in the not too far distant future the motive power for traction will be unlike that of the present, and that with the advance of electric science its wider application for traction purposes is inevitable. This is recognised by Mr. Donald A. Matheson, M.I.C.E., engineer-in-chief of the Caledonian Railway, who, in delivering his presidential address at the inauguration of the session of the Glasgow Association of Students of the Institution of Civil Engineers, remarked that "the steam locomotive was now shadowed, if not absolutely threatened, by the electric motor." This statement, emanating from so important a source, and supplemented by the utterances of other prominent railway officials, marks a significant change in the attitude of railway authorities. Dealing more particularly with the work of railway engineers in the future, Mr. Matheson indicated that the tendency, rather than in the construction of new railways, was in the direction of betterment by the widening of existing lines, the providing of additional accommodation, and the extension and improvement of the great terminal stations for goods and mineral traffic, as well as for passenger traffic, in the principal cities of Europe, as well as of the United States. Improvement in permanent way had also in recent years been most marked.

Rand Power Scheme.—In the *Times* engineering supplement Prof. W. E. Ayrton reverts to the proposed electric transmission scheme from the Victoria Falls to the Rand, and disputes the statements made in an interview with a contemporary by Mr. Wilson Fox, manager of the British South Africa Company, relative to the possibility of such a scheme being commercially successful. He condemns the comparisons made between the power schemes at Victoria and Niagara, as the latter only delivers electrical energy over a distance of 30 miles while the former proposes to deliver it over 745 miles. At present the Rand consumes about 150,000 h.p. at a cost of something like £20 per year per horse-power. Niagara sends 24,000 h.p. to Buffalo, 30 miles away, and sells it at 0·7d. per horse-power hour to an eight-hour consumer, which is equal to £25. 11s. per horse-power year. There is a plentiful supply of coal in the neighbourhood of Johannesburg. Estimates have been obtained and the accurate analysis made of about 20 different kinds of coal, giving the specific gravity and the percentages of carbon, ash, volatile matter, coke, as well as the evaporation factor, with the result that at a price of 10s. 5d. to 12s. a ton excellent coal can be delivered on the Rand itself. How is it possible, therefore, asks Prof. Ayrton, to "transmit electric energy 745 miles and sell it more cheaply than it can be obtained from coal on the spot." He also points out the dangers from native nterference with the line, and summarises his objections to the scheme in the sentence that "such lengthy transmissions, more than three times as long as have ever yet been made, because more than three times as long as even the enterprising Americans have ever yet considered commercially possible, could certainly never succeed in such an unsettled country as South Africa."

Birmingham Local Section.—The opening meeting was held in the large lecture theatre of the university on Nov. 23. The attendance numbered 86. Dr. Sumpner having taken the chair, congratulated the members on the success of the previous session's work, and pointed out that not only had all the papers been published in full in the Institution *Journal*, but that two of them had been awarded premiums. In cordially welcoming Prof. Kapp, who was present with them for the first time, he said that among his many great services rendered to the electrical engineering industry, perhaps none was greater than that rendered

Digitized by Google

when in 1885 he pointed out, simultaneously with Dr. Hopkinson, the true theory of the magnetic circuit and made it clear to dynamo designers. Dr. Sumpner then vacated the chair in favour of Prof. Threlfall, after thanking the members for their support during his term of office. The new chairman proposed a vote of thanks to Dr. Sumpner for his services as chairman, which had been performed with such conspicuous ability. This was carried with acclamation, after which Prof. Threlfall delivered his address on "Some Problems in Electro and Electro-thermal Chemistry." Mr. R. A. Chattock proposed a vote of thanks to the chairman for his address, alluding to the importance of the introduction of new materials for making lamp filaments. All were interested in following up discoveries which were leading to an increase in the efficiency of incandescent lamps. The motion was seconded by Prof. Gisbert Kapp, who expressed admiration for the skill with which the chairman had dealt with a difficult subject, for electro-chemistry and metallurgy had been unfortunately too much neglected by electrical engineers. He thanked the audience for their kind reception of him as a member of the section.

Books Received.—We have received from Messrs. S. Rentell and Co., Limited, London, a third edition of "The Application of Electric Motors to Machine Driving," by Mr. Andrew Stewart, A.M.I.E.E. (2s.), which has been rewritten and enlarged so as to include the more recent developments in this system of electric driving.—The *Proceedings* of the Royal Society of Edinburgh (vol. xxv., No. 11) includes among its contents a "Note on Some Generally Accepted Views regarding Vision," by Dr. W. Peddie; a "Note on the Boiling Points of Aqueous Solutions," by the Rev. S. M. Johnston, B.A.; and "A Comparative Study of the Dominant Phanerogamic and Higher Crytogamic Flora of Aquatic Habit in Three Lake Areas of Scotland," by Mr. George West (with 55 plates).—The *Bulletin* of the Imperial Institute (vol. iii., No. 3) contains an article on rubbers from Burma, which gives the results of analyses made with products of the plant Ecdysanthera micrantha, and Parameria penduncolosa. The chemical examination of the dry material of the former plant gave the following results: caoutchouc, 84·1 per cent.; resin, 11·5 per cent.; insoluble matter, 4·4 per cent. (of which 1·3 per cent. was ash). The composition of the latter was revealed as follows: resin, 88·5 per cent.; caoutchouc, 10·7 per cent.; insoluble matter, 0·8 per cent. Material possessing such a very resinous composition as the latter product would have very little commercial value. It appears, however, that further investigations may be made in view of the favourable opinion expressed upon the product of this vine in Java and Sumatra. The *Bulletin* contains also a long article on the production and uses of asbestos, and an announcement that the Natal Government is offering to lease the rights of rubber collection of certain portions in the Ingwavuma district of Zululand.

Society of Arts.—The first of the series of four Cantor lectures for this year was delivered on Monday last by Dr. J. A. Fleming, F.R.S. The subject chosen was "The Measurement of High-Frequency Currents and Electric Waves." At the outset the lecturer said that the determinations of Cavendish were comparable with those made to-day, for the reason that he measured in the same units. The capacities of different bodies were best found experimentally, as was also the inductance. Those associated with large engineering schemes were apt to imagine that the measurement of these small inductances was of little importance, but, as he showed, in the case of high-frequency currents small inductances and capacity were of very real significance. A principal property of high-frequency currents was that they were entirely on the surface of the conductors. It was very important to study spark resistance. A method of spark counting which he had devised had proved of great service, and had thrown fresh light on certain investigations. Spark resistance was a very complex thing, depending upon many things, of which the chief were the capacity of the jar, the inductance of the circuit, the length of the spark, and the shape of the spark terminals. Spark resistance had been measured in another manner by Prof. Slaby, of Charlottenburg, and his experiments showed that with increase of spark length, and with increase of capacity, there was a rise in resistance. Dr. Fleming said that he had found that the material of which the spark balls were composed had a marked effect on spark resistance from giving a higher resistance than zinc or brass. It was also noticeable how great was the effect of length of spark upon resistance, as had also been demonstrated by Slaby. There were, however, many anomalies, and the work of various investigators did not show agreement; but the results were not necessarily contradictory, being rather due to the different kind of spark employed. This referred particularly to the experiments of Rempp. Numerous diagrams and experiments were introduced to illustrate the lecture.

Three-Phase Railways.—An inspection of the Valtellina three-phase railway, which connects the towns of Lecco, Sondrio, and Chiavenna, and skirts the picturesque borders of Lake Como, was recently held, and in the *Electrical World and Engineer* is given particulars of the results achieved, together with a description of the general equipment. According to the official time-table the daily train miles are 1,400, and the ton-miles about 268,000, allowing 134 tons for passenger trains and 313 tons for frieght The total energy developed at the generators is 10,000 kilowatt-hours per day, including that required for lighting and for the workshops. The energy generated per ton-mile would, therefore, be about 37 watt-hours, but as this is measured at the generators, the actual average required for propulsion per ton-mile would be less, corresponding to a very economical result. The three 2,000-kw. generators in the power-house, of which one is held in reserve, are tended by 12 men, and for the maintenance of the 65 miles of double overhead line 26 men are employed, while 45 men supervise and maintain the sub-stations and rolling-stock. Twelve motormen in addition complete the staff. The total expenditure per annum amounts to £4,780, or 11·7d. for the working cost per 1,000 ton-miles. Of this total, £889 is spent in the power-house, £1,438 is required for the maintenance of the overhead equipment, £1,368 for the electrical equipment of cars and locomotives, and £1,085 for motormen. In contrasting these figures with the cost of operating steam locomotives it is stated that, on the basis of 1,400 locomotive miles per day, the corresponding cost of steam traction would be £23,250, or nearly five times as much as with electric. The plant is driven by water power from an exceptionally fine source, the turbines operating under a head of about 100ft. As this line, forming part of the Adriatic Railway system, was formerly operated by steam, the comparison quoted was doubtless based upon actual performance, but as cheap coal cannot be obtained in the district, the great difference between the figures would be accounted for to a large extent by the entire elimination of the cost of fuel for the electric system.

Power in Sweden.—Formerly industries in Sweden were largely dependent upon outside sources for the means wherewith to obtain energy for power or lighting purposes. The coal production of the country is very small, and her requirements were met from supplies from abroad. Now, however, she is turning her attention to the rich resources

Digitized by Google

which she herself possesses, and bringing energy to bear in their development. The enormous peat fields are being worked for their product, which is largely substituting foreign coal on the goods wagons in the service of the State railways, and the *Elektrotechniker* announces that the waterfalls in the country are being utilised for the supply of electric power. This journal states that a company has been formed in Halmstad—the Sydsvenska Elektriska Aktiebolaget—for the purpose of working the supply from the Laga in Southern Sweden, which flows from Bolmsee in Kronoberg into Laholms Bay on the south-west coast. Seven power stations will be erected on its banks, the first at Bolmsee, whilst the others will be placed at various points on the route, all connected with one another. Power will be transmitted south as far as Eslöf and north to Halenstadt. In addition, there will be a number of branch stations, and the total length over which the power will be transmitted will be 300 km. With the completion of the first portion of the system a total of 13,000 h.p. will be ready for use, whilst the final completion of the works will almost double the amount of power for disposal. The cost of construction of the stations and equipments is estimated at 14 million kronen (about £771,457), of which 1½ million kronen (£82,656) will be expended on the plant and machinery. It is anticipated that the price of power will be sufficiently low to enable it to compete with the cheapest of its rival methods. A definite demand in the locality is already guaranteed, so that the profitableness of the undertaking is assured. Furthermore, it is understood that current will be utilised on some of the railways and in collieries for power and lighting purposes. The erection of stations and equipments is being undertaken forthwith, so that it will be possible to supply current in two years.

Electrical Engineers (R.E.V.).—Notwithstanding the fact that this corps has only been in existence for nine or ten years, the record which already stands to its credit is one of which the officers and men may well be proud. From humble beginnings they have worked their way up to the position which they at present hold, one unique among branches of the volunteer service, and the number of men enrolled in their ranks now amounts to 800. This success is in a large measure due to the fact that in their case intellect goes together with strenuous work and a sense of military discipline. The Government have recognised that in them the nation has a valuable accession to its defensive forces, and in the matter of camping have not failed to accord special facilities to suit the convenience of the men. On Saturday evening last a good muster of officers and men met a number of guests (including officers from the regular army) at the Café Monico on the occasion of their annual regimental dinner. The chair was taken by Colonel R. E. B. Crompton, who took a leading part in founding the regiment. The toast-list was discreetly brief, and, after the loyal toasts were duly honoured, the Chairman proposed "The Army," which was responded to by Colonel W. Pitt, R.E. (Eastern Command), who referred to the close connection between the Electrical Engineers section of the Royal Engineers and the army, and incidentally mentioned that the 350 men who went out to South Africa during the late campaign had greatly distinguished themselves. Colonel N. M. Lake, C.R.E., proposed "The Corps of Electrical Engineers," and in so doing took occasion to remark that the Electrical Engineers were engaged in duties such as they would be in war, and, therefore, the value of their services was greatly enhanced. Colonel Crompton replied to this toast, and pointed out that the efficiency of the men as volunteers depended upon their efficiency as electrical engineers, and that the training given in the corps was to the end of the men gaining a livelihood. The toast of "The Guests" was proposed by Major B. Hopkinson, and responded to by Lieutenant-Colonel Sir E. P. C. Girourard and Prof. John Perry. The toast-list was interspersed by an excellent programme of vocal selections.

Yorkshire Local Section.—An ordinary meeting of the Local Section of the Institution of Electrical Engineers was held on the 23rd ult. at the University of Leeds, when a paper was read on destructors and their by-products by Mr. F. L. Watson. After describing the progress which had been made in destructor design, Mr. Watson proceeded to a consideration of the financial side, and indicated the manner in which economies could be effected by the utilisation of by-products. He then went on to explain the details of various types of destructors, and afterwards discussed the allocation of cost and returns as between the destructor and the electricity works, and the management of the joint undertaking. If the cleansing department ran the destructor and sold steam to the electricity department, it would be run for sanitary purpose, and might not give its maximum results when the electricity department wanted them; if by the electricity department, it might be run for steam regardless of sanitary considerations. Again, if the sanitary department was to be paid for steam, how was the quantity to be ascertained? Mr. Watson said he knew of no satisfactory method, since the quantity used in the destructor itself was generally more or less uncertain. The value of the steam per ton could be easily ascertained from the cost of raising the same quantity by means of coal. The ideal method would appear to be to drive an independent generating set from the destructor, and to work this set as near as possible at a constant load, crediting the destructor with the actual output. If the generating set could also be retained in the control of the cleansing department, and the current delivered by meter to the electricity department, it was better still. A well-known surveyor said recently that most of the electricity generated by destructors was produced by friction between the two departments, and if that was so, it was deplorable that the ratepayers' money should be so wasted. Mr. Watson thought that these questions might find a solution in the increasing responsibilities undertaken by cleansing departments, such, for example, as the combination of a works department for the whole corporation, the manufacture of clinker products, and the lighting of stables, workshops, and staff dwellings, and streets in the vicinity of the plant, or the sale of power to neighbouring manufacturers.

Ramsgate Tramway Accident.—The report of Lieut.-Colonel P. G. von Donop, R.E., upon the accident on Aug. 3, when a car running down Madeira-hill got out of control and fell over a cliff, a height of about 32ft., has just been issued. The responsibility for the accident is placed upon the motorman, who did not apply his brakes judiciously when travelling on a steep gradient. Madeira-hill is about 230ft. in length, and opposite Albion House, where the accident occurred, according to Board of Trade regulations a stop has to be made by all cars before descending the hill. From this point down to the end of Madeira-hill the gradient is a continuously falling one, varying from 1 in 13 to 1 in 16. In addition, there are a number of sharp curves in Madeira-hill; the only one, however, concerned in this accident is a reverse curve, which commences at a point about 35 yards below Albion House. At this point there commences a left-handed curve of 66ft. radius, and about 30 yards in length. Almost immediately at the termination of this curve there commences a right-handed curve of 73ft. radius. There is practically no straight at all between the two portions of this reverse curve. Owing to the gradient and curves, speed down Madeira-hill is restricted to

Digitized by Google

three miles an hour. In this case the front wheels of the car ran round the above-mentioned left-handed curve successfully, but immediately that they met the commencement of the right-handed curve they were derailed towards the left of the line, and the accident occurred. The superelevation at the point where the wheels left the line was ½in. in the wrong direction—that is to say, the rail on the inside of the curve was ½in. higher than the outer one instead of the outer one being the higher of the two. With the authorised speed of three miles an hour this want of superelevation would, however, have been immaterial. The inspector reports that the actual derailment was due to the sharpness of the curve and the high rate of speed at which the car ran round it; and with this high speed, the derailment was further facilitated by want of superelevation at the point where the wheels left the line. The gradients on Madeira-hill are not considered excessive provided the brakes be in good order, but, owing to the car becoming a total wreck, it was not possible to ascertain this. Colonel von Donop reports that the arrangement of the lines on Madeira-hill where this accident occurred is susceptible of improvement, but it is understood that the company intend to take steps at an early date to carry out certain alterations with that object. The only other point to which attention is drawn is the method of applying the slipper brake, and the inspector considers that the arrangement was not satisfactory, though it did not appear to have contributed to the accident in any way.

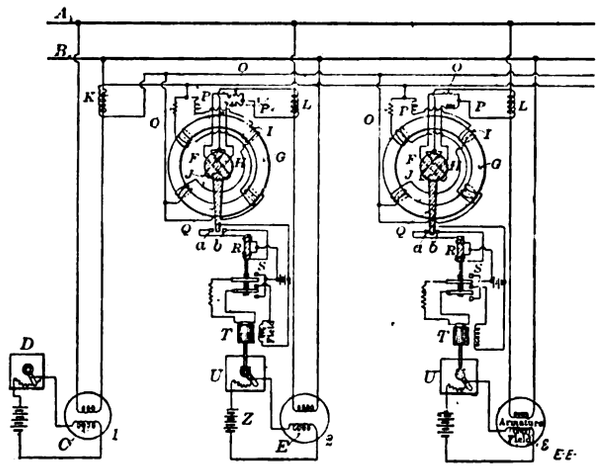
Commercial Progress.—For two or three years past, adherents to a certain school of economic thought have gone about the country pointing out to us that trade is declining, that our commercial supremacy is threatened, and that the break-up of the Empire is inevitable. To revive our declining industries and to avoid the terrible catastrophies which lie ahead, we are urged to accept and apply certain changes which are advocated by those disciples. Whether their diagnosis of the case is the correct one or not, or whether the measures prescribed are likely to be remedial, it is not our purpose here to discuss. Certain it is, however, that the fears which they convey have disturbed the mental calm of a great number of individuals to such an extent that an impartial examination of the question is not attempted and underlying causes more and more obscured. It is consoling, therefore, to transcend this atmosphere of doubt and apprehension, and to inquire into other factors which bear upon our foreign commerce. Reference to all records—official and otherwise—which indicate the actual state of the nation's commerce, are sufficient to allay our misapprehensions about impending disasters. Nevertheless, there are matters which if properly attended to cannot but extend our foreign trade. And of these, the most important is the consular service. It is because this branch of the civil service is not too well organised and adequately controlled and remunerated that much valuable information as to the requirements of and possibilities in the world's markets is not available to our manufacturers and merchants. European and American consular services are placed by their respective Governments on a much higher status than are ours, and, consequently, are able to supply their people with more extensive information. Only the other week we called attention in these notes to an American consular report on the possibilities of a wider application of electricity to lighting and traction in China, and other reports which are constantly being brought to our notice convince us that one of the great defects in our foreign trade is that our manufacturers do not know the requirements of the world's markets, and that they are not aware of what is being offered there by their foreign rivals. This view is largely borne out by the speech delivered before the Liverpool Chamber of Commerce last week by the Marquis of Lansdowne, who said that if we were outclassed in different parts of the world it was not because of the inferiority of our goods, but because of the greater adaptability and resource shown by some of our rivals in different branches of trade It is satisfactory to learn, further, from the same source that treaties have been concluded with foreign countries whose markets are neutral whereby our goods are allowed to enter under the most-favoured-nation treatment, and that future prospects are by no means so gloomy as depicted by others.

Institution of Electrical Engineers.—There was a large company present at the meeting held on the 23rd ult., when Colonel H. C. L. Holden read his paper on the "Applications of Electricity in the Royal Gun Factory, Woolwich Arsenal." The President (Mr. John Gavey), in opening the meeting, referred to the sad loss of Mr. G. A. Grindle, who was one of the victims of the ss. "Hilda" disaster. Mr. Grindle had been a full member of the Institution since the early eighties, and a vote of condolence with his family was passed in silence. Colonel Holden then proceeded with his paper (which we are producing elsewhere), which gave a most interesting account of the electrical applications introduced into the Government workshops, and was followed with keen interest by the members. At the invitation of the chairman, Prof. Ayrton rose to open the discussion, and, in so doing, said that it was a matter for congratulation that mechanical power had been substituted by electrical power, and he emphasised the advantages accruing from the better light which was possible in the workshops following the substitution. As instancing the rapid development of the application of electricity in factories, he stated that while in South Africa he had noticed that in a large electrical works in Central Pretoria the machinery was driven electrically. There the equipment consisted of a line shaft driven by a single motor, and he wished for an expression of opinion from Colonel Holden as to whether it were more advantageous to employ a separate motor for each tool or lathe, or whether all tools should be attached to a line shaft driven by a single motor. Prof. Ayrton stated further that an idea which he found to be generally put into practice in America was that the machine and motor were complete—*i.e.*, the casting of a tool or lathe or other machine was made to receive the motor. The only serious objection which he had heard against that practice was on account of the greater vibration. Mr. Russell followed in the discussion, and said that, with regard to the use of worm gear described by Colonel Holden, the experience which he had had with that class of gear at Silvertown had clearly established its advantages. Though the initial cost is greater, the wear is so small that repair is not required, and smooth running is gained. He pointed out the wonderful way in which the electric cranes worked, and he thought that Colonel Holden had too modestly refrained from sufficiently emphasising this point. Mr. A. W. Marshall wound up the discussion by asking what precautions were taken at the factory, where so much electrical machinery was in operation, to prevent a sudden cutting off of current? Replying to Prof. Ayrton, Colonel Holden said it was difficult to draw a hard-and-fast line between driving machines with separate motors and line shafts, each particular case having to be decided upon its merits. He himself favoured the line shaft when such were possible, for it would be found that the cost of driving tools by separate motors and switches would form a serious objec-

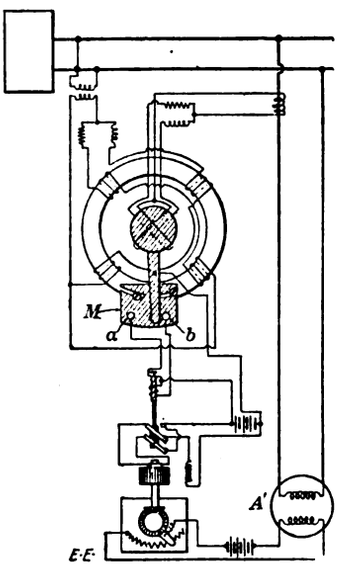
Digitized by Google

tion. With regard to practice of building the motor complete with the machine, Colonel Holden thought it advisable to do so in some cases, especially in those where there is no reduction of gear. A special department was appointed to control the supply of current to the Arsenal, but there were multiple mains and a good many generating sets in case of need. On the motion of the chairman, Colonel Holden was cordially thanked for his interesting discourse.

Phase Regulator.—The general principles of a proposed phase regulator are described by Mr. P. G. Watmough, jun., the designer, in the *Electrical World and Engineer*. Briefly speaking, the apparatus consists of a selective device, responsive only to phase displacement in combination with and actuating a relay mechanism, which controls or varies the field exciting current supplied to the generator or other alternating-current apparatus whose phase displacement it is desired to adjust through the medium of its field excitation. In the accompanying illustration the two magnetic field members of the indicator placed concentric with each other are marked G and H. The inner field is pivoted so that it can rotate through a considerable angle. Polyphase field windings, preferably arranged for diphase currents, are placed on each member, so that a rotating field flux may be obtained in each structure when the windings are suitably energised. In order that the instrument may be used as a phase regulator, a swinging index arm, mounted on H and arranged so that



it will swing over a graduated scale, is equipped with a contact device arranged to close one or other of two relay circuits, the energising of which sets in motion a motor that is suitably geared to the field rheostat of the machine whose field it is desired to control. One of the applications of the device is seen in Diagram 1. A B represent the 'bus bars or lines; C E, separate excited fields; D, field rheostat, hand control; F, phase regulator; G H, field members of regulator; I J, polyphase windings; K L, current transformers; O, resistance coil; P, inductance coil; Q, contact arm; R, relay, plunger, and coils; S, reversing switch; T, motor armature; U, field rheostat; Z, any source of excitation. The encircled windings, 1, 2, 3, represent single-phase alternating-current generators. Should any of the machines, say generator No. 2, have insufficient excitation, its current will be displaced in phase from the current flowing in generator No. 1, due to the lower terminal E.M.F.; this phase difference will cause the moving element and contact arm of the phase regulator connected between generators 1 and 2 to assume a certain position dependent upon the amount of phase displacement existing. If the contacts, *a* and *b*, are so adjusted that at zero phase displacement the contact arm just swings clear of both contacts, then the above phase displacement and resulting position of the arm will close one or other of the contact points; one of the local relay circuits is thus energised, which through the medium of relay coil, plunger, and reversing switch starts into action the small motor operating the field rheostat, connections being such that the direction of rotation will cut out resistance, thus strengthening the field of generator No. 2. A corrective force is thus applied to the existing phase displacement, which will be gradually diminished by the increasing field strength, until zero phase difference exists between generators 1 and 2. When this condition obtains, however, the regulator arm will assume its former position—wherein the contact arm swings clear of either contact—breaking the relay circuit, which thus allows the motor switch to fly open, and hence stops further movement of the rheostat motor. It has been found that in stations where there are many units operating together the above arrangement not only increases the efficiency of the plant—through the suppression of the wattless magnetising or demagnetising currents circulating between machines, which result is now approximately obtained by hand adjustment—but it also eliminates the time and attention now required of the switchboard operator in securing the above adjustment. Among its other applications is one for the automatic maintenance of a predetermined power factor between any machine and the circuit to which it is connected. This is effected by



but a slight modification of the arrangement, as shown in Diagram 2, where A' represents the armature of field circuits of the machine to be adjusted. Another application is for the automatic maintenance of constant voltage. Merely the relay and operating mechanism previously described are retained, the selective device or phase indicator being replaced by a voltmeter mechanism, the movable arm of which performs the same service as rendered by the contact arm in the phase regulator, closing one or other of the contact points, *a* or *b*, depending upon whether the voltage rises or falls below a predetermined value. The device may also be applied to the control of phase displacement due to speed variation. Actual operating conditions may require combinations of the above applications, thus it might be desirable to maintain a group of several rotary converters in phase unison with each other, utilising the connections illustrated in Fig. 1; the "master machine" of the group, however, if connected as in Fig. 2 would determine the power factor at which all the rotaries would tend to operate. Different methods have heretofore been suggested for meeting one or more of the above applications, but the author is of the opinion that the particular mechanism proposed embraces several points of novelty, especially the idea of utilising a "master machine" to which other machines on the circuit may be cophased.

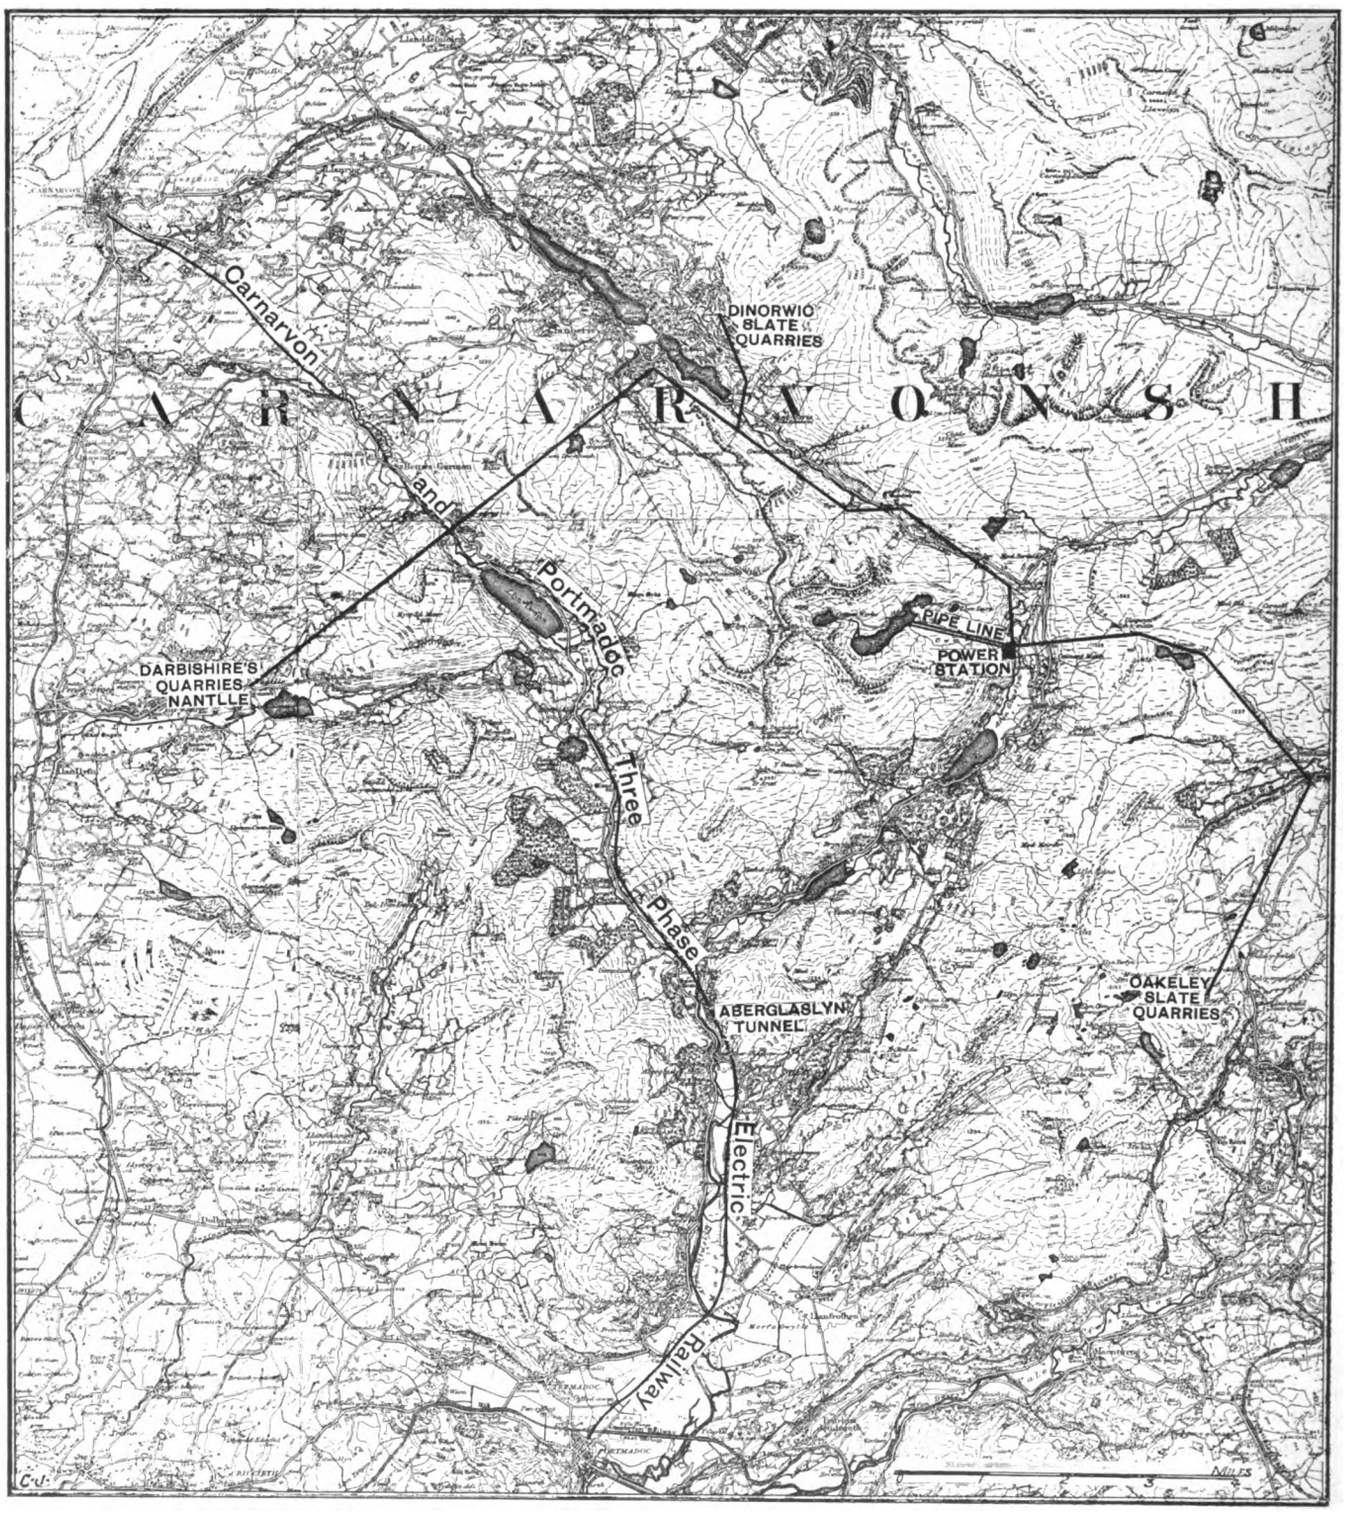
NORTH WALES ELECTRIC POWER SCHEME.

Contractors' Dinner.

Through the courtesy of the editor of the *Contract Journal*, we are able to reproduce an account of a dinner which he attended at the Victoria Hotel, Llanberis, on Saturday last, Nov. 25. We are also permitted by him to reproduce some photographs showing the class of contractors' work which this large power scheme involves. The editor of the *Daily Express* kindly lent us three of the photographs, but, unfortunately, we could not get in time for reproduction those photographs used in the excellent description of this scheme in the *Daily Express* for Nov. 23. We hope to give a technical description of the scheme when the plant is officially opened in the early part of next year.

The dinner given by Messrs. Bruce Peebles and Co. to celebrate the partial completement of their extensive contract for the North Wales Electric Power and Traction Company was held in the Victoria Hotel, Llanberis, on Nov. 25. The large hall of the hotel had never before seated so many guests, but the host proved quite equal to his task. Covers for 174 visitors were laid, and the hall, when the guests were seated, presented a gay appearance. The guests included local quarry owners, tenant farmers, and the large staff of men employed in the works. Dinner was served in good style, and everyone did full justice to the excellent viands set before them. The place of honour



Map of the Snowdon District, showing the Work of the North Wales Electric Power and Traction Co.

on the toast-list was, of course, given to "The King," and was proposed by the genial president, Mr. M. T. Pickstone, the able director of Bruce Peebles and Co., in his usual inimitable style.

The North Wales Electric Power and Traction Company were complimented in a few appropriate words by Mr. Brinkman on their enterprise in the huge undertaking they have in hand. Mr. Brinkman is the manager of the Dinorwic slate quarries, which are to be equipped for electric driving. Mr. Aitchison was put down in the

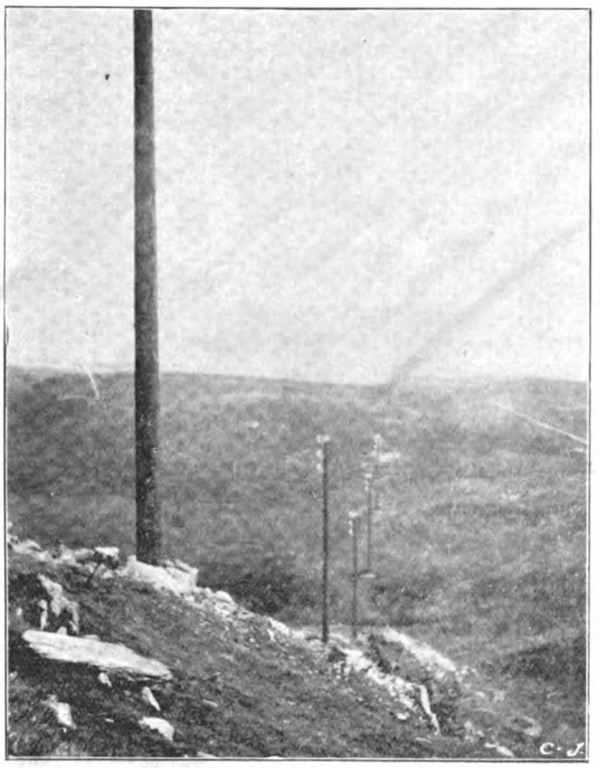
list for this toast, but had wired his great disappointment in being unable to be present that evening, and Mr. Taylor, the superintendent of the works for Messrs. Harper Bros.,



The Pole Line to Roman Bridge.

ably took his place. Between toasts a recitation was given by Mr. D. H. Jones on "Our Job," composed by one of the employés for the occasion, and hitting off

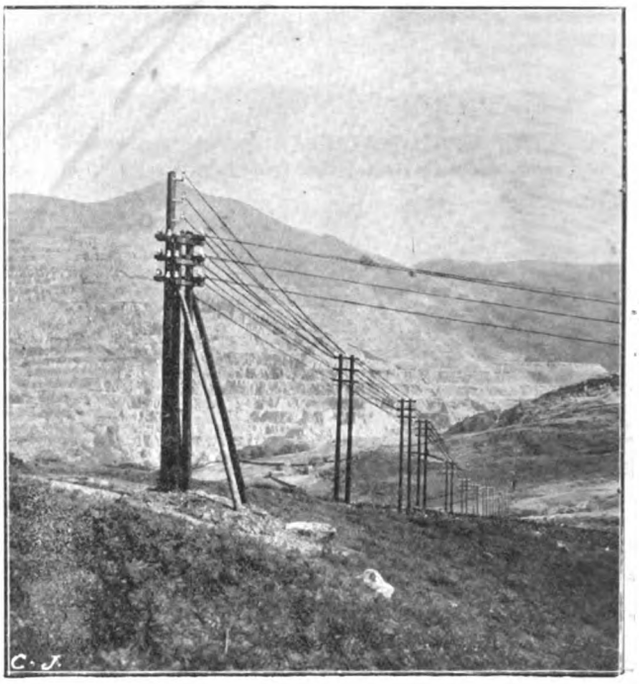
to a nicety the various personalities at present working in Messrs. Bruce Peebles' interests. The rendering received prolonged applause. Messrs. Bruce Peebles and Co. had a warm champion in Mr. T. C. Kerr, who had come all the way from London to speak of his admiration for the company. He sketched in a most interesting manner the growth and development of that firm from small beginnings up to its present great size, and how Mr. Pickstone had thrown his whole



A Turn in the Line near Llanberis, showing Slate Quarries in background. (*Daily Express* Photograph.)

energies into its development. He also gave a list of some of the new contracts the firm had lately obtained, and from that one judged how it would in future become a power, not only in the land, but through the British Empire spreading still more the impression that Britain is not by any means so backward in business as some people say and think.

Entrance to Aberglaslyn Tunnel. (*Daily Express* Photograph.)

Mr. M. T. Pickstone had certainly to take a meed of praise for himself in his reply to the toast, but said that the whole success of any business depended on the way one's assistants backed one up, and his present men had never given him a moment's disturbing thought in the way they had carried out instructions for this contract. Mr.

Digitized by Google

W. V. Waite, the engineer in charge of the whole work, had given him great satisfaction doing work of sterling worth. Mr. A. W. Beutell, sent down from Edinburgh perfectly inexperienced in this new work, had, by his tact, commonsense, and keen interest in his work, made himself a name in that part of the world, and would, he felt sure, rise to still greater prominence in the future. This contract had proved a record in many respects, 30 miles of transmission lines having been erected in the course of five months, and much of this in almost inaccessible places. The scheme was also unique in character, being the first high-tension hydro-electric power scheme in this country with transmission by bare overhead conductors. Three-phase alternating current was generated by alternators direct driven by Pelton wheels, the head of water being 1,100ft., and the turbines being fed by duplicate pipe lines 1¼ miles long, with pipes 30in. in diameter. Each of the four sets of Pelton wheels and alternators already installed would develop 1,500 kilovolt-amperes. The power was to be used principally in the slate quarries situated within a radius of 15 miles. The power would also serve to supply current to the North Wales Narrow-Gauge Railway and its extensions, all of which were being carried out by the firm, the result being a complete narrow-gauge electric line from Carnarvon to Portmadoc. The line, when completed and electrified, would be 30 miles long, with nine transformer stations, the current being transformed to 600 volts for supply to the two overhead wires feeding the three-phase motors on the trains. He also referred to the many large contracts that the firm have at present on hand, not only in Great

Britain, but also in Canada, South Africa, China, South America—in fact, in all quarters of the globe. Mr. Pickstone then proposed the toast of "Mr. Aitchison, general manager of the North Wales Power Company, and of the North Wales Narrow-Gauge Railway, and the Portmadoc, Beddgellert, and South Snowdon Railway Company," all of which companies are directly interested in the scheme, the two latter about to be worked electrically. In the unavoidable absence of Mr. Aitchison, Mr. Wells, resident engineer at Beddgellert, replied.

Mr. W. V. Waite proposed "The Visitors," responded to by Dr. Mills Roberts.

Mr. H. T. Beutell proposed "The Tenants," responded to Mr. Close.

Mr. A. W. Beutell proposed "The Men," which was replied to by Mr. Ovenden and Mr. W. Owen, who said the firm and their representatives had taken a genuine interest in the men, and by their fair and even generous treatment of them had won not only their esteem, but the affection of both the staff and the rank and file. They would pardon almost any delinquency but "scamped work" or work not strictly in accordance with the book, with the result that they had secured sound and substantial work such as would for many years successfully resist the assaults of the tempests and hurricanes for which Snowdonia is notorious. The men, in expressing their high appreciation of the honourable treatment received, most cordially wished Messrs. Bruce Peebles and Co. the long and prosperous career which they so richly deserved.

The great feature of the evening's entertainment was the excellent musical interludes. One felt in listening to these worthy exponents of Welsh musical fame that here one was right in the centre of a world of music. The reception the performers got was most cordial, one encore not by any means being judged sufficient. One or two truly Welsh songs were sung, and Mr. Kerr, a man near to the Biblical limit of three score and ten, gave us in charming style a couple of Scottish national songs. When the time for parting came it was with extreme sorrow that such a unique evening should have any limit at all, but the near approach of the "Sawbath" compelled all to seek their various ways, after singing in true Welsh fashion "John Jones," etc.

We need only add that our photographs and the map will show the extent of the scheme and the difficulties overcome by Messrs. Bruce Peebles and Co. under the able guidance and to the plans of Sir Douglas Fox and Messrs. Harper Bros., the consulting engineers to the North Wales Power and Traction Company.

SHUNT-WOUND TRAMWAY MOTORS.

BY A. JOHNSTON, A.I E.E.

The adoption of shunt-wound motors for tramway work has caused a large number of engineers to shake their heads in doubt as to the result in practice of such experiments Usually, a shunt-wound motor designed for stock will have a much lower starting torque than a similar series-wound motor—in fact, the same calculations will be used, except, of course, the size of the field conductors, both motors being designed to run at normal load with the same field strength, and the field saturation at normal load will not be carried into the sloping part of the curve. As this practice has been carried on from the beginning, it has firmly established the idea that the starting torque of series motor is greater than a shunt motor. Users of the two have found it to be the case, and have taken it as a natural consequence.

Improvements in commutation have been made which allow considerable variation in the strength of field without serious sparking at a fixed position of the brushes, that reduce the difficulties standing in the way of varying the speed by varying the field strength. Commutation in the later series motors gave little trouble owing to the fact that a heavy current was never commutated in a weak field, the field being always strong when the armature current was great. If the field is excited independently of the armature current, it is, of course, possible to have a heavy current commutated in a weak field, and in constructing controllers for shunt-wound primary motors precautions are necessary to prevent this being carried to a point that will injure the motors.

The torque of any motor is approximately proportionate to the product of the field strength and the armature current, or

$$T \propto N\,C, \text{ then } T = k\,N\,C.$$

It makes no difference how N, the field strength, is maintained, whether by a shunted current or by C, the armature current; but it is evident if saturation is not carried beyond the bend of the curve, that in the series-wound motor

$$N \propto C, \text{ and } N = m\,C; \text{ therefore } T = k\,m\,C^2;$$

and in the shunt motor with the field excited by a constant current, N will be constant and $T \propto C$.

Still assuming that the saturation of the field is not carried beyond the straight portion of the curve, if the phrase is not contradictory, it is seen that, while the torque of a series motor varies as the square of the armature current, the torque of a shunt motor varies with the current simply; and these facts alone would indicate that the torque of a series motor when starting (at which time the armature current will probably be at its highest value) will be greater than that of the shunt motor, and if the field strength was not a factor of the torque in both cases, the truth of this indication would be clear. The fact remains, however, that N is a factor of the torque, and there is no reason why a shunt motor should not have as high a value for N as a series motor when starting. How long this high value of N can be maintained without injury to the field coils is quite another matter, for the winding space in tramway motors is very limited and the ventilation is bad; consequently, if the rate at which heat is generated is high, it cannot be continued for more than a brief period without endangering the insulation of the coils, and on this account the current in the shunt circuit must be reduced soon after starting by inserting external resistance in the circuit, which, of course, means some loss of energy and a lowering of the efficiency of the motor.

The curves in Fig. 1 are for two motors of exactly the same design and size except that one, A, is series wound and the other, B, is shunt wound The manner in which the tractive effort falls as the speed increases is very striking, but it must be remembered that this, in the case of B, the shunt-wound motor, depends on and is under the control of the operator. In making out these curves, the armature current in B is kept constant at full working value by varying the field strength, while the current in the armature and field of A is controlled only by the speed, unless field shunts are used. The two tractive effort curves show that the acceleration of B compared with A is less when starting and at slow speeds and greater at moderate and high speeds, and in this it holds a great advantage in that it lessens the strain on the gear and truck and the discomfort of the passengers. The same motor will, of course, give a different curve if differently operated—in fact, a great deal depends on the operator; and if cars fitted with shunt-wound motors are to be run on lines having long heavy gradients, he must be well trained and reliable, so that he will not injure the motors by allowing the car to travel too quickly and take too much current when ascending these heavy gradients. This, if it could not be overcome, would be a serious defect; a tramway motor that depends greatly on a reliable motorman would be scrapped at once by ninety-nine out of a hundred managers The trust, however, can be transferred from the motorman to the car circuit breaker by adjusting the latter to open when the current rises beyond a safe value, but as a circuit breaker, too, is inclined to err, one should be fixed on each end of the car and connected in series in place of the usual arrangement of a circuit breaker at one end and a switch at the other. The motorman will soon find out the correct position for his controller on each particular hill and will not go beyond it, for should he do so he will be put to the trouble of stopping the car, closing the circuit breakers, and starting again. This arrangement also prevents the motors being abused by the conductor holding the circuit breakers closed; he cannot hold both at the same time in

Digitized by Google

his endeavour to assist the motorman to get home quickly on the last trip at night. Usually more harm is done during the last trips than at any other time.

Two shunt-wound motors with their armatures connected in series and their field coils similarly connected will work well and each will take a fair share of the load, but when connected in parallel difficulties arise. If the pair of wheels connected to one motor varies in diameter with the wheels coupled to the other, the load will not divide equally between the two motors—one will do more work than the other to some extent, small or great according to the difference in the sizes of the two pairs of wheels. Take, for example, the first pair of wheels to be 30·25in. in diameter and the second 30in.; this would only mean $\frac{1}{8}$in. all round the wheel, and is often exceeded in actual practice, accounted for by the quality of the wheels and brake blocks varying. The armature speed in revolutions per minute will be the speed of the car in miles per hour multiplied by 50 in the first instance, and in the second case the multiplier will be 50·42. If, at a speed of 10 miles per hour or 500 r.p.m., the first rotor takes 20 amperes, its counter E M F. will be:

Impressed voltage – armature current × armature resistance; or if the armature resistance is ·5 ohm,

$$500 - 20 \times \cdot 5 = 490 \text{ volts};$$

and if the field of the second motor is of the same strength, since it will revolve at 504·2 r.p.m., its counter E M.F. will be

$$\frac{504 \cdot 2}{500} \text{ of } 490 = 494 \text{ volts.}$$

Its armature current will then be

$$\frac{500 - 494}{\cdot 5} = 12 \text{ amperes};$$

thus showing that this slight difference in the wheels causes one motor to take only 60 per cent. of the current taken by the other.

Again, it may be shown that if the field of one motor is slightly stronger than the other, it will make a considerable difference in the current taken by the two motors when working in parallel. Suppose that the first motor takes, as before, 20 amperes, and that its counter E.M.F. is 490 volts, then if the second motor runs at the same speed but with its field, say, 1 per cent. weaker, its counter E.M.F. will be

$$\frac{99}{100} \text{ of } 490 = 485 \cdot 1 \text{ volts},$$

and its armature current will be

$$\frac{500 - 485 \cdot 1}{\cdot 5} = 29 \cdot 8 \text{ amperes},$$

or nearly 50 per cent. more than the first motor. This extra load would cause the motor to become hotter, which in turn would weaken the field still more, and so on. It may be concluded, therefore, that to run shunt-wound motors in parallel on a tramcar in the usual way is certain to lead to serious trouble. This difficulty with the field strengths may be overcome by leaving the field coils connected in series always, no matter how the armatures may be connected, which will keep the ampere-hours the same in each. The only variation which can then take place will be due to the magnetic circuits, and if care is taken to keep the material in these the same, it should not be serious.

If shunt-wound tramway motors are to be worked with economy, the shunt circuits must be broken every time the car is stopped in order to prevent waste of energy in them, and each time this is done a destructive arc will be produced at the contacts owing to the high self-induction of the coils. Seeing that it is necessary to stop a car about 1,000 times a day, these contacts which carry the shunt current will give considerable trouble, and should they fail to make connection at any time the safety of the armatures will depend on the working of the car circuit breakers. It is a very rare occurrence for the field coils of a series motor to become short-circuited owing to the small potential difference between the turns, and if a current is allowed to flow through the motor, it may be taken almost as a certainty that it will have its proper field.

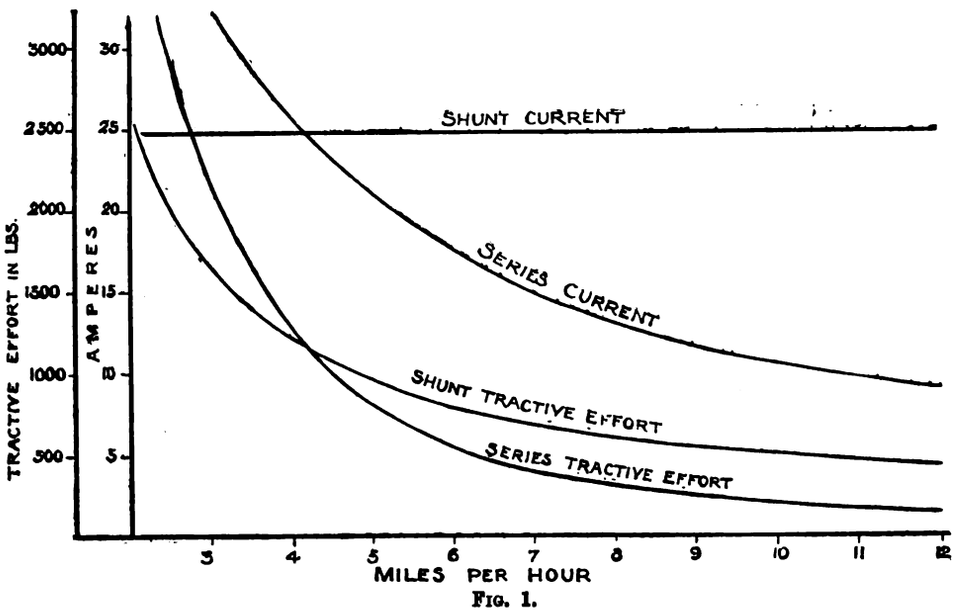

FIG. 1.

Shunt-wound motors can be used for controlling the speed of the car when running down hill or reducing it when on a level road, and when doing this they will return energy to the line, which can be used again by other cars. This action reduces the wear and wear on the wheels and brake blocks considerably, but puts more work on the motor armatures in just the same way as the rheostatic brake, except that in the latter the energy is wasted in resistances. It will take a fixed amount of energy to reduce the speed of the car a certain amount in a certain time that energy is taken from the car through the medium of the motors, and either returned to the line or absorbed in resistances. In either cases the strain on the motors will be the same. On most tramway systems the use of the rheostatic brake as a service brake is strictly prohibited, owing to its destructive effect on the motors. If shunt-wound motors are to be successfully employed to control the speed of the car in both positive and negative acceleration, their dimensions must be carefully worked out, and the size of the cars and steepness of the gradients on which they are to work taken into consideration. It is unreasonable to expect motors that have been converted from the series to the shunt type by simply altering the field coils to work as well on the same cars as before this alteration was made; the conditions are so different. If the motors were only just large enough to deal with the positive acceleration of the cars, it is certain that if they are used to retard the speed as well, their life will be short. There is a difference in the braking action of series

Digitized by Google

and shunt wound motors when generating, in that the former will bring a car to almost a dead stop, while the latter will only reduce the speed to three or four miles per hour. This difference, however, is not so great as it might appear at first sight, for if, before the braking action is started, the car is travelling at, say, eight miles per hour, it will not retain half its kinetic energy at four miles per hour, but a much less quantity, since the store of energy in the car varies not with the speed simply, but with the square of the speed—that is,

$$E_k \propto v^2 \text{ and } E_k = a\,v^2,$$

and at a speed of four miles per hour

$$E_k = 16 \times a.$$

At a speed of eight miles per hour

$$E_k = 64 \times a.$$

Thus it will be seen that, while series motors can convert all the kinetic energy stored in the moving car, shunt motors can convert only 66 per cent. of it, assuming these speeds. In retarding a car from travelling beyond a certain speed when descending a gradient, the same amount of energy must be converted whichever type of motor is employed.

When a short-circuit occurs on a section of tramway on which shunt motors are running, it will be more violent, owing to the motor acting as generator and the car circuit breakers having to open in addition to the station circuit breaker.

THE APPLICATIONS OF ELECTRICITY IN THE ROYAL GUN FACTORY, WOOLWICH ARSENAL.*

BY COLONEL H. C. L. HOLDEN, R.A., F.R.S., MEMBER OF COUNCIL

(*Continued from page 737.*)

Grindery.—As in most modern workshops, it is the custom to grind the workmen's tools for them, and not to allow them to do this for themselves in the old-fashioned haphazard way on a grindstone. In the grindery devoted to this work some 12 Gisholt tool-grinders are continuously in use, and the problem to be solved was to drive them in the most economical and efficient manner. The grinders were arranged half on either side of the shop, and driven by belting (Fig. 8) from a shaft running at very nearly the same speed as the wheels, and coupled direct through a flexible coupling to a 6-h.p. shunt motor standing on a bracket fixed to the wall. The speed of the shaft is 1,400 r.p.m. Besides the tool-grinders there are also two small cutter grinders, and in order to drive these latter, which are placed across the shop, it was necessary to have a shaft running at right angles to the other two. As the power required was small, this motion was transmitted by a friction disc and wheel, the wheel being advanced so as to be in contact with the disc when it is required to rotate the shaft, which consists of a thin steel tube, and runs at 2,500 r.p.m. Some doubt was expressed as to the life of these high-speed shafts and bearings when they were first erected, but as they have been working for the last three years with practically no wear, it is evident there is no need for apprehension that they will not last. The economy in transmission here is considerable, owing to there being none of the usual countershafting; it is not uncommon to see machines of this sort driven from a high-speed motor, which, from a small belt pulley on its own shaft, drives a large one on a countershaft, which again drives by means of another large pulley the small pulley of the grinder. The best wheels for use on these grinders for high-speed tool steel have been found to be carborundum ones. Carborundum, as we know, is itself electrically produced at Niagara Falls.

Rifling Machine.—The method of driving of a large rifling machine for 12in. guns is shown in Fig. 9. The term "rifling," of course, is applied to the operation of cutting the grooves which run spirally along the bore of a gun. In order to do this, a bar carrying one or more tools to cut the grooves is drawn through the gun, and turned as it is moving to give the required twist. The saddles which guide the bar are carried on a bed, within which is the screw for actuating the bar; as this screw revolves in one direction or the other, so the bar is moved in or out of the gun—cutting is always done by pulling the bar through, not pushing it, and, indeed, I may remark that in boring operations it is always better to have the cutter bar in tension than in compression—the end of this screw is coupled to a shaft passing right through the gear box, and

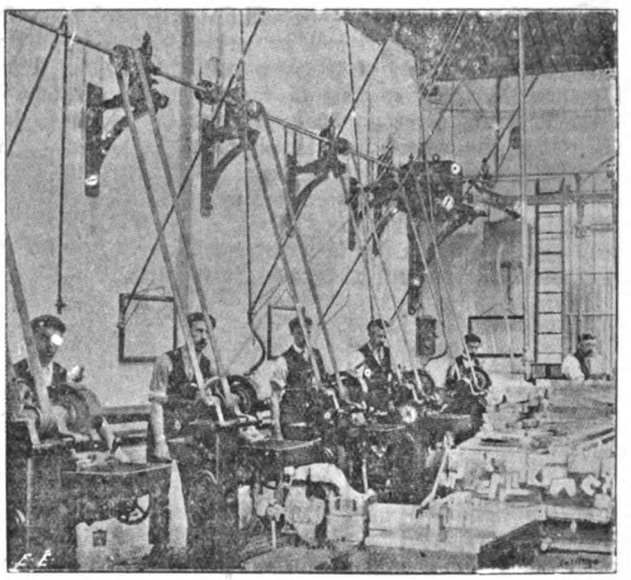

FIG. 8.

supported in the bearing shown on the left of it in the picture. This shaft carries two magnetic clutches (Fig. 9), one on either side of the gear box. The motor of 30 h.p. drives a pinion which is always in gear with the teeth of the large internally geared wheel, and also with a small spur wheel, running on the same centre as the former, but, of course, in the opposite direction. A clutch on the left connects the screw shaft to this latter wheel, whereas the clutch on the right attaches it to the internally geared wheel. It will be obvious that the direction of rotation of the screw shaft will be different according as one clutch is in action or the other, and owing to the different ratio of the gears a quick return motion when not cutting is obtained. The motor and the gears run continuously in one direction, and, therefore, there is only the momentum of the screw shaft and inertia of the screw and saddles with the rifling bar to overcome on reversal of its motion. The action of reversing is entirely automatic, and worked by the movement of the rifling bar saddle. This drive works very smoothly and well—it enables the rifling

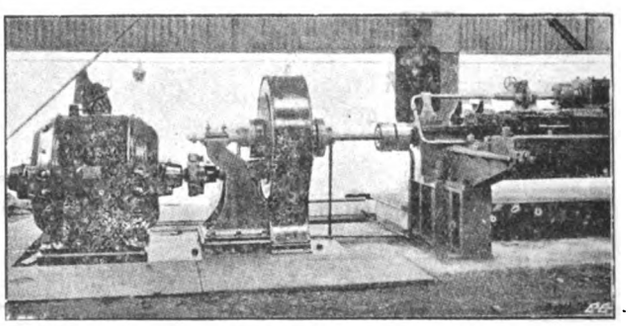

FIG. 9.

of a 12in. gun to be carried out in 40 hours, six grooves being cut simultaneously, whereas only a few years ago the same operation, with one tool only cutting, took more than three weeks, working day and night; no less than 26 cuts have to be taken to finish each set of grooves, and I am able to show specimens of the shavings taken. In contrast to this machine, I have an illustration of another driven by the older method of crossed belts, which go through the usual shrieking performance whenever the drive is reversed. Within the last few weeks, however, this latter machine has been dismantled in order to lengthen

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

it, and fit it with a driving gear similar to the one already described.

For lapping the bores of guns, an operation which has to be done in order to get the extreme uniformity of diameter that is necessary in the bore, both during manufacture and sometimes after the gun has been in use, there are three machines in the factory for dealing with various sizes of guns. Two of these were designed to be driven by separate motors, and the third was converted to an electric drive. I may remind you that the operation of lapping is performed by means of an expansible lead-covered block or head

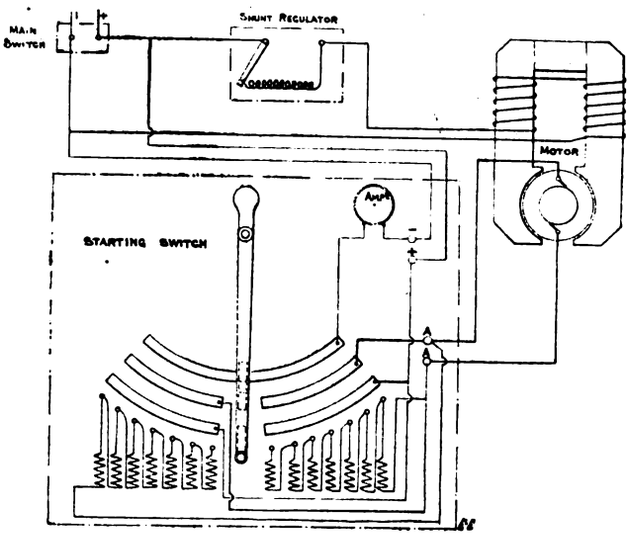

FIG. 10.

charged with abrasive material, such as emery or corundum, which is attached to the end of a rapidly revolving shaft, and is capable, whilst revolving, of being moved from one portion of the bore to the other. A short and rapid to-and-fro motion should preferably be given to this head, so as to prevent the cutting of rings in the bore. The largest of the three machines is devoted to the larger guns, such as the 9·2in. and the 12in., and the motor is mounted above the saddle which carries the lapping shaft, and drives the latter by means of a short link belt. The large pulley is attached to the shaft by a feather sliding in a feather-way cut the whole length of it, and in this manner rotates the lapping head. The saddle is traversed backwards and forwards along the bed by a screw extending the whole length of the bed and similar to the leading screw of a lathe. This screw, however, is stationary, and the traversing motion of the saddle is produced by means of a revolving nut, which is driven also by a linked belt and through reducing gear from a pulley carried on the other end of the motor shaft. The quick to-and-fro motion is given to the bar by the sleeve, which is clamped on to the bar between the two cheeks of the saddle, and has cam grooves around it in which guide blocks fixed to the saddle are made to engage when required. The liquid reverser, worked either automatically or by hand, is in front of the starting switch. The tightening of the belt is accomplished by sliding the motor across the saddle, and can be done by the hand-wheel when the machine is running. The next size of machine is somewhat similar in design, but the motor is underneath the bed, and drives by gear entirely; the motor is not easily accessible, and is more liable to damage from emery and oil, and is mentioned more as an example of how not to do it. I must add, however, that it works very well. A diagram of the switch connections is shown in Fig. 10.

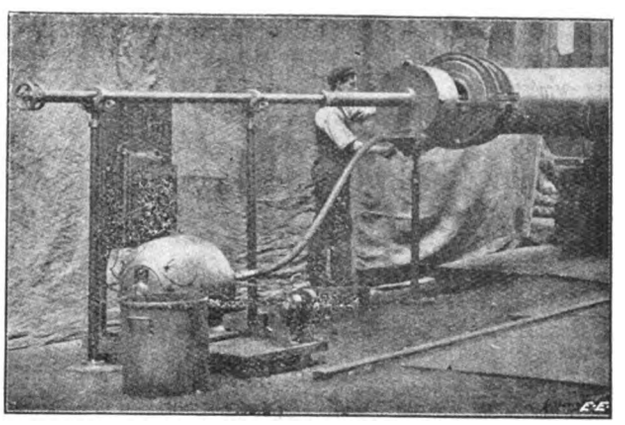

FIG. 11.

The smallest machine, situated in the north-east shop, is really a converted lathe, and is devoted to the smaller size of guns up to 4·7in. I mention this as a practical example of the advantages possessed by magnetic clutches over the old system of reversing by a shifting belt. The machine originally had two shifting belts with loose pulleys and a fast pulley between them, on to which the belts were shifted in turn for reversing the direction of motion of the screw actuating the saddle. The central pulley was done away with, and magnetic clutches were applied to the other two either one of these can be energised by a rocking switch actuated by hand or automatically. The result of this change was to enable the saddle screw to be run much quicker than before, the reducing gear between the pulleys and the screw being removed, and the latter driven direct, while the motion is reversed silently, instead of with a screeching of belts and clashing of gear. Altogether four magnetic clutches are used with this machine, two on the main shaft, one to drive the headstock which rotates the gun and another to drive the open and crossed belts, and

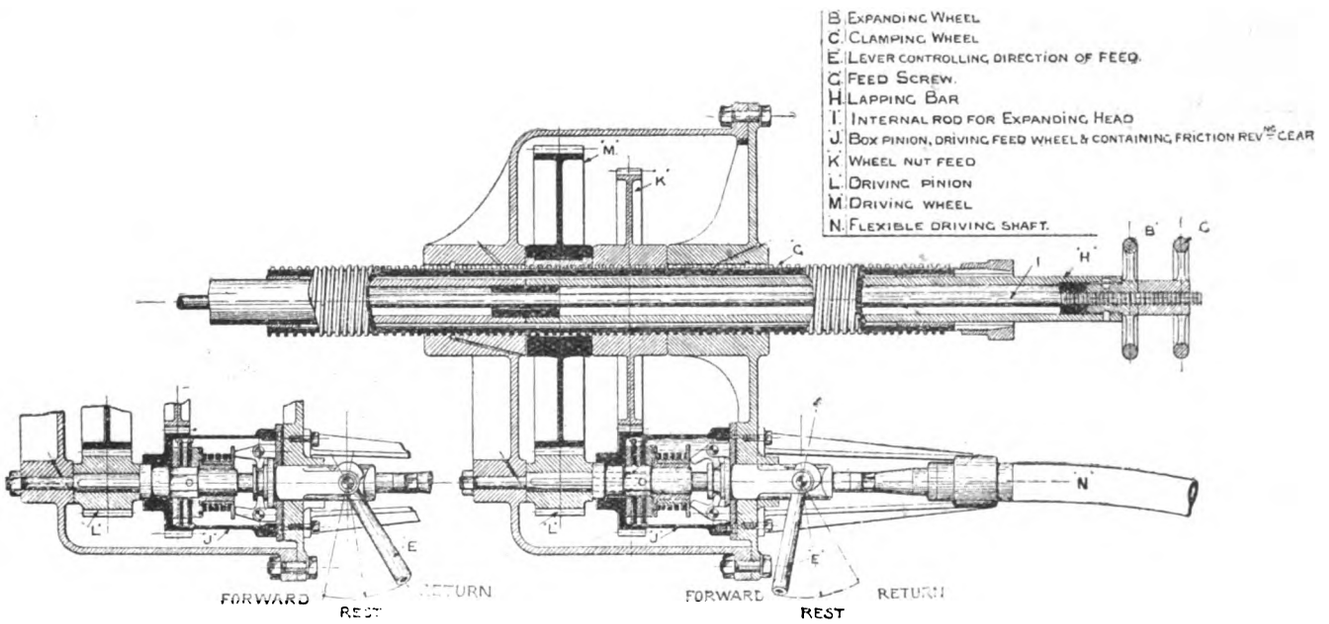

FIG. 12.

Digitized by Google

then there are the two already described. This may seem a somewhat extravagant number to employ on one machine, but it is justified because the machine is not one that is in constant use, and the power absorbed by running three belts idle is very considerable, and quite a large figure when compared even with the total capital cost of the clutches, instead of the interest thereon and depreciation.

An illustration is also given of a portable electric lapping machine (Fig. 11) for use on board a ship or elsewhere. The machine itself, which embodies most of the features of the large machine, is here attached to the muzzle of the gun, and rotation is imparted from the motor to the machine by a flexible shaft (Fig. 12). The forward and

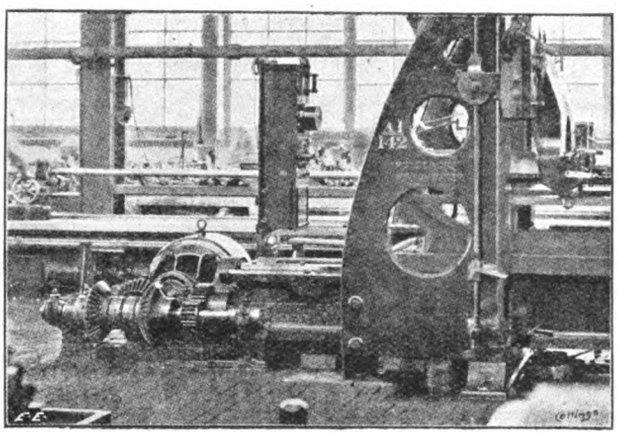

Fig. 13.

backward feed of the lapping head is obtained by means of a friction clutch, controlled by a small lever, which regulates the movement of the nut through which the screw feed bar passes. If the nut is held still, the bar advances at the highest speed; if the nut is allowed to revolve at the same speed as the bar, no forward or backward movement takes place; and if the nut is driven faster than the bar, the motion of the latter is a backward one. In the first case the friction clutch is out and the nut held; in the second case the nut is free to revolve; and in the third case, the friction clutch being in, the nut is revolved at a higher speed than the bar, and so the bar is withdrawn. The power required for a lapping machine is always out of all proportion to the weight of metal removed, and in this case a motor of 6·5 h.p. is necessary.

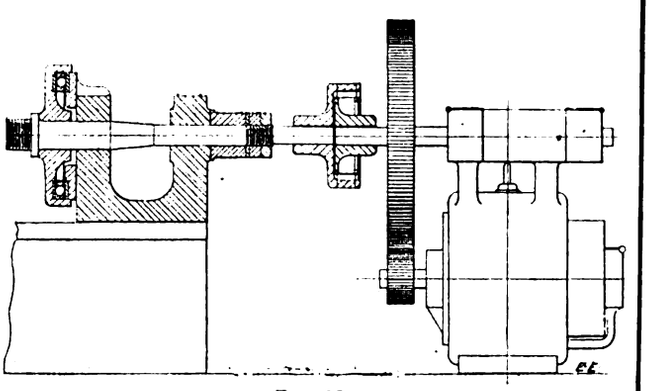

Fig. 14.

We now pass to the electrically-driven planing machines, and I may here say that, so far as planing machines generally are concerned, I am in favour of cutting in both directions with two separate tools whenever and wherever it is possible, the economy in power, time, and labour being greater than having a quick return stroke, for it is obvious that, however rapid the return stroke may be, time is lost, and no useful work is done. This will explain why the gear is so designed that the speed of the table in either direction is the same. In the case of planing machines, as in the case of the boring machines, I hold a strong brief for the screw drive as against the rack and pinion drive. The former undoubtedly does the better work. The planing machines are driven by a shunt-wound variable-speed motor, which runs continuously in one direction, and drives, by means of a bevel pinion, two bevel wheels revolving in opposite directions (Fig. 13); these two bevel wheels are concentric with the shaft which drives the screw of the planing machine, and are each furnished with a magnetic clutch, by which they can be attached to the shaft; the clutches are alternately energised by a rocking switch, actuated by adjustable tappets on the bed of the planer. The reversing action of these machines is very quick and silent. No check or change of speed is discernible in the motor, though, of course, the ammeter shows a momentary rise of about 25 per cent. on the reverse. The special shaping machines used for interrupting the screw threads in the breech openings of guns seem very well adapted to driving in pairs, and this arrangement has, therefore, been adopted. The motor drives a countershaft placed above it, and the two machines are driven each by

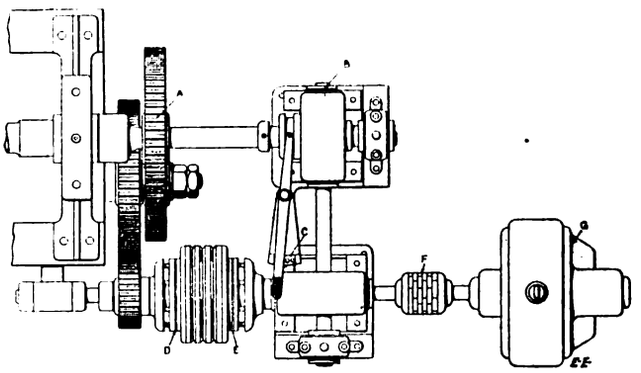

Fig. 15.

its own magnetic clutch from this countershaft by belting. Mention may also be made of a heavy vertical milling machine, which was not originally designed for electric driving, but had to be converted. Though I am not in favour of very short belt drives when there is a difference of diameter between the driven and the driver, yet in this case it was almost the only arrangement possible, and, in point of fact, it has been very successful, the motor being supported on a Γ-shaped bracket attached to the upright of the machine, and to the portion of the frame carrying the driving shaft.

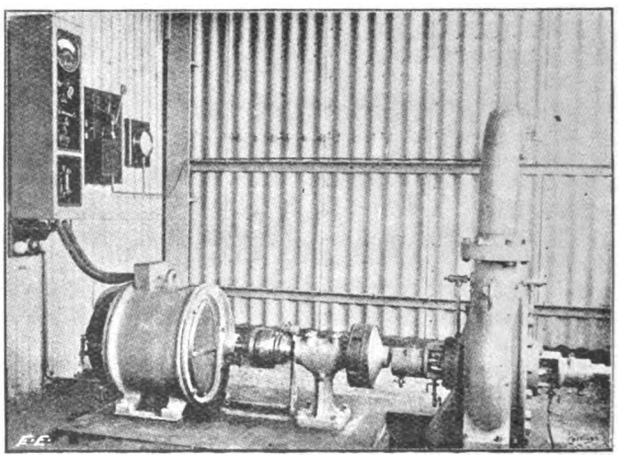

Fig. 16.

Earlier in the paper I described a separate feed arrangement for a large boring machine, and I now propose to illustrate a smaller one for high-speed solid boring fitted with a somewhat similar arrangement. The machine itself has a mandrel, which is driven by a motor through a single-reduction gear, for the reason that, although it would have been preferable to drive it direct from the motor shaft, this was not practicable owing to the comparatively low speed required The thrust of the boring tool (which is very considerable) is taken by a ball bearing of large diameter forming the back of the face plate (Fig. 14), a device which has been very effective. The feed gear is shown in Fig. 15. This, as in the other example, fulfils two functions—viz., that of the actual feed of the tool into the work, and also the quick withdrawal and

Digitized by Google

advance of the same. In this instance two clutches are used in conjunction with a claw clutch, and besides the safety arrangement provided to prevent the feed gear running after the headstock is stopped, or being started before the other is in motion, there is also a switch worked by the lever actuating the claw clutch, which prevents the two clutches being operated simultaneously, or even the wrong one being operated. When the feed is in operation the motor is clutched to the first worm-shaft and turns the first worm-wheel, which in turn drives the worm of the second worm-wheel, and the claw clutch being engaged, the screw is driven, and the saddle carrying the boring bar advanced. If now it is desired to withdraw the bar rapidly, the claw clutch is withdrawn, and the motion of the lever effecting this allows the second magnetic clutch to be rendered active, and this clutches the pinion to the motor shaft, and drives the spur wheel through the intermediate wheels. The speed of the carriage when feeding varies from 33in. to 115in. per hour, whilst the quick return is from 7in. to 24in. per minute, or nearly 13 times faster.

In the south boring mill it used to be the custom, as elsewhere, to have each large boring machine supplied with cutting lubricant by a small and separate plunger pump, but a short time since it occurred to me that it would be preferable to have a constant and general supply from one

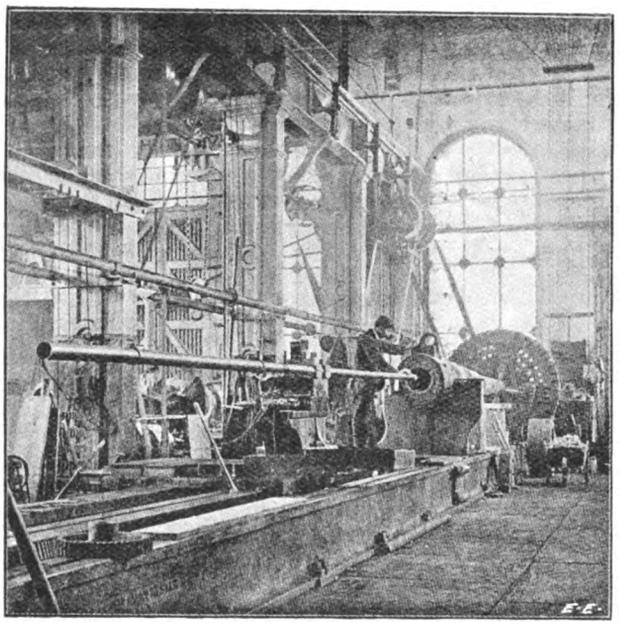

FIG. 17.

source, and to do away with the small separate pumps. A high-lift centrifugal pump, driven direct from a motor, appeared to be the most suitable pump for the purpose, and the pressure required being only 30lb. per square inch, an old boiler was utilised as an accumulator and air-vessel to maintain the pressure. The motor is coupled to the pump (Fig. 16) through a magnetic clutch and flexible coupling, and runs at 1,200 r.p.m., the clutch being used to connect or disconnect the two when the pressure falls below or rises above the amount that the automatic switch is set for. It is somewhat remarkable to see the extremely quick, and yet, as it must be, gradual action of the clutch in starting the pump, which is, of course, started from rest with a full head—there being no appreciable delay or shock in so doing. This installation has proved so successful that a second set is being obtained, to enable the whole shop to be supplied. The motor of the second set will be so arranged that it will only be started when the first set cannot meet the requirements. The pump takes 14 s.h.p., and lifts 300 gallons per minute. Once having introduced magnetic clutches into the workshop, it is astonishing how quickly their applications seem to spread, and I propose to devote a few minutes to describing one or two special examples.

In the testing-room there is a small piece of apparatus which is used for compressing to a predetermined amount the copper cylinders employed in guns for ascertaining the pressures developed by the explosive; for instance, if a 15-ton per square inch pressure were anticipated, a copper pressed to 12 tons per square inch might be used. The pressure required is obtained by the weight of a column of mercury, the height of the column being varied by the displacement of the mercury by a piston of considerable area in a cylinder connected with the column. The piston is moved by a vertical screw, driven through gearing by an electromotor, the copper cylinder being between two flat and hard steel surfaces interposed between the end of the screw and the piston. Means are provided for starting, stopping, and reversing the motor, but in order to get the practically instantaneous stoppage of the screw when the mercury has reached the correct height on the scale for the pressure required, a magnetic clutch is fitted as close to the screw as practicable, and is found to answer the purpose admirably, the switch controlling it being operated by the man's foot. The motor can then be stopped, reversed, clutched in, and the pressed copper removed and replaced by another, and so on, the whole process taking longer to describe than to carry out in reality.

Electricity has been of assistance to us in enabling the amount of eccentricity of the bore of a gun which, as sometimes happens, has from one cause or another become bent, to be readily ascertained. You will, I am sure, appreciate the difficulty in first of all ascertaining, and secondly actually measuring, the want of truth in the bore of a gun 20ft. to 30ft. from the breech end, which distance it may easily be, as the 12in. gun is 45ft. in length. The means adopted, however, are, thanks to electricity, quite simple (Fig. 17).

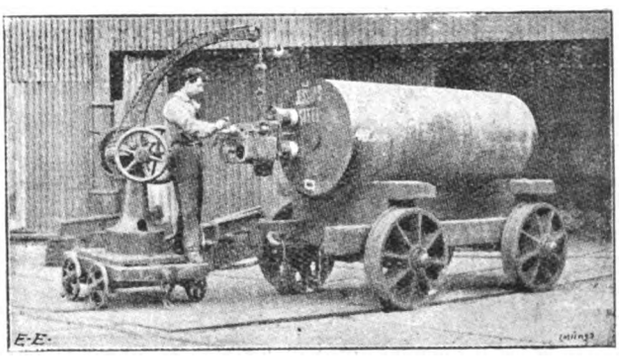

FIG. 18.

A tapered steel tube, stayed and tied with a single gun wire so as to bring both ends of the tube to the same level, carries at one end a knife-edged contact wheel about 2in. in diameter, this wheel being insulated from the tube, but connected to a flexible conductor passing down the interior of it to the other end of the tube, which is fixed in the slide rest; a dead-beat galvanometer and a couple of dry cells complete the equipment. When the wheel touches the metal of the gun, the circuit is completed through the galvanometer, which indicates accordingly. The movement of the slide rest, necessary to make contact, reveals the amount of eccentricity. When any billet of steel arrives in the factory, the first thing to be done is to obtain a small quantity for chemical analysis. This is generally taken in the form of fine drillings from a point midway between the centre and exterior of the billet (Fig. 18) and at both ends. Until current was generally available throughout the factory, this was quite a lengthy operation, involving the loss of time taken to fix a ratchet brace, and then the time to drill the hole in order to obtain the shavings; by the aid of the electric drill the time lost in fixing is eliminated entirely, and the drilling by power is quite a short operation.

I feel that my list of applications would not be complete if I omitted to refer to the use of the electromagnet for lifting projectiles (Fig. 19), which was introduced by me many years ago when the 110-ton gun was in use. The cast-iron projectiles for proof were exceedingly awkward things to remove from the pile and sling for the crane to lift; this was made delightfully easy by substituting an electromagnet for the sling. The magnet used consisted of one piece of mild steel of ⌐¬ section, and 10in. in length, with a single-coil wound round it longitudinally—the sur-

Digitized by Google

face magnetised was 30 square inches, and the maximum weight it had to support 1,800lb., the weight of the projectile of the 110-ton gun, though, as you will see, there was ample power to spare. The weight of this magnet, complete with the shackles for attaching it to the crane hook, was under 56lb., and the electrical energy required for the maximum lifting power was 120 watts. In any large gun factory, or, indeed, in any factory where large makes of steel are heated, forged, and tempered, or otherwise treated, it has long appeared to be absolutely essential that some means should be provided of measuring temperatures. This is

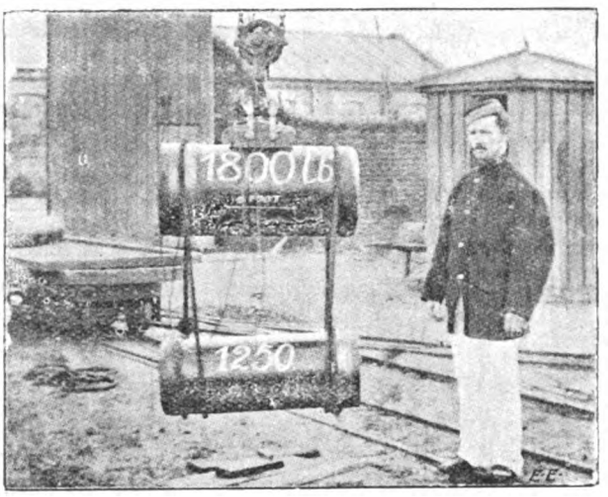

FIG. 19.

most conveniently done by electrical means, and without going into the history of the matter and a description of the various instruments that are available for the purpose of measuring temperature electrically, I will merely say that, for our purpose, the measurement by means of the E M.F. generated by a thermo-couple has been found to be the best adapted.

The thermo-junction we use is a platinum and iridio-platinum one, in conjunction with a modified form of d'Arsonval galvanometer to measure the E M.F. which indicates the temperature. The instruments are fixed in

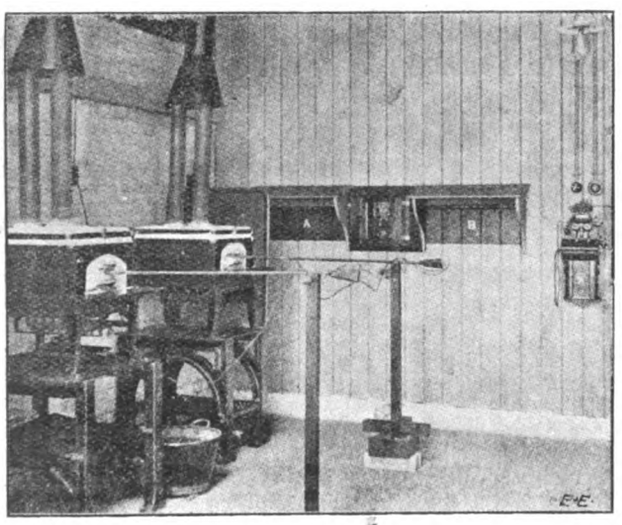

FIG. 20.

various parts of the factory, and connected up to the re-heating, annealing, and tempering, etc., furnaces, as also to the lead baths (Fig. 20) for tempering steel specimens in such a manner that the temperature of any one of them can be immediately ascertained by those in charge, and regulated accordingly; but this is not all. From each of these centres, so to speak, line wires are led to the metallurgical laboratory, where there is a standard recording instrument, and by this means not only can a continuous record be taken of any operation desired, but the individual instruments can be, and are, constantly checked to ensure accuracy and uniformity with the standard, for which purpose the points are connected by telephone. The standard itself is checked by the usual method of observing the freezing points of pure metals at various points of the scale. The zero of all the instrument scales is the temperature of boiling water, which, where steam is always available, as in our case, is readily arranged for, and is in itself a check on the accuracy of the instrument.

Automatic Water Clutch.—A difficulty arose in connection with the starting into motion of the heavy saddles of some double-ended boring lathes, by the 1½-h.p. motors that had been supplied with them, and after some trouble with burnt armatures and fuses the following arrangement was tried with complete success. The solid coupling was removed

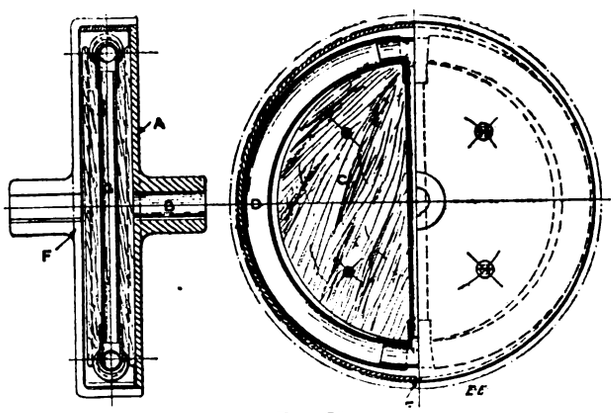

FIG. 21

and a disc of cast iron, A, was keyed to the motor spindle, B (Fig. 21). This disc carries a block of hard wood, C, on its face, the periphery being prepared with a semicircular groove to carry an indiarubber tube, D. This indiarubber tube is in halves, which are joined by a metal tube, G, let in across the diameter of the wooden disc. Outside the indiarubber tube is a split cast-iron ring, E, similar to a piston ring, attached loosely to the iron disc so that it is free to expand. The tubes are then filled with water, and the whole arrangement is fitted into a cupped disc, F, keyed to the shaft to be driven When the motor is at rest the two portions of the clutch do not touch each other, but when the motor is started, and as it gains speed, the water, acted on by centrifugal force, expands the rubber tube, and this in turn expands the split ring, which eventually rubs against and then grips and drives the other half of the clutch.

To sum up, there are at work at the present time in the Royal Gun Factory 134 motors of an aggregated rated horse-power of 1,903, whilst there are 61, either connected or ready to be connected to the supply mains when current is available, of an aggregate rated power of 840 h.p. more. They consist of one motor of 100 h.p, one of 50 h.p, six of 40 h.p., thirty of 30 h.p., two of 25 h.p., eleven of 20 h.p, twenty-nine of 15 h.p, and thirty-nine of 10 h.p, the remainder being under 10 h.p., and ranging down to 1 h.p. The largest motors—viz., 100, 50, and 40 h.p.—are all connected to individual machines. The number of magnetic clutches in use is 117, thirty-one rated at 25 h.p. and eighty-six at 6 h.p. Of magnetic chucks and holders there are 16 in use, but fresh fields of application are continually being found for them, and their numbers are, therefore, constantly on the increase. Magnetic holders are of the greatest service in connection with surface-grinding machines, and enable small steelwork to be turned out with the greatest accuracy and rapidity. One instance may be given of the utility of the magnetic lathe clutch, and that is in turning obturator rings. These rings are made from extremely hard-tempered steel—so hard, indeed, that they can only be cut at a very low speed with specially hard tools—yet it is found that in spite of the small surface area they afford for the magnetic attraction, and also of their somewhat low permeability, the magnetic chuck is the most effective method of holding them whilst being turned that we have yet been able to devise. There is nothing very special in the construction of these magnetic devices; they are designed with a view of taking the standard size of bobbins used in the clutches, and by filling the air-gap

Digitized by Google

with brass are so made that they cannot be damaged in any way by being used in oil or water.

It may be of interest, I feel, if I add a few data as regards the amount of material removed per electrical horse-power per minute on various machines—the electrical horse-power is the gross amount required not only to drive the motor and machine but also to do the work (Table A)

BOILER-HOUSE ECONOMY.

An interesting paper on the subject of "Boiler-House Economy" was read by Mr. A. W. Bennis, M.I.M.E., A.I.E.E., before the Huddersfield Society of Engineers, on the evening of the 22nd ult., Mr. W. M. Carnock, M.Sc., B.Eng., in the chair. A short digest of the paper may be given as follows: The lecturer started with some observations on wasteful coal consumption, and proceeded to point out where unnoticed losses may creep in. He then described an ideal chimney, flue, economiser, and boiler installation. He pointed out that the chemistry of combustion is included in practice, and described and advocated the calorimetry of fuel. Instructive data were supplied which showed incontrovertibly that by the use of mechanical stokers, small sized fuels, at low cost, may be burned with advantage. He then dealt with the question of heat transmission through boiler plates, and brought out clearly the advantages of complete combustion and high furnace temperatures. In considering the chemical composition of the waste gases of combustion, a table of the percentage losses through excess of air in combustion was shown. Mr. Bennis then dealt briefly with mechanical stoking, detailing its advantages and describing the different types of stokers. He subsequently passed on to consider the subject of elevating and conveying systems, and their relative merits and the savings effected by their use. The lecture was brought to a finale by a description of an installation of elevating, conveying, and machine stoking plant at Messrs. Martin, Sons, and Co., Limited, Lindley, Huddersfield. Several lantern views were shown, among them being the plant at Messrs. Martin's, which included the electric coal truck now so well known to readers of the leading technical papers and those interested in boiler-house labour-saving appliances.

EDINBURGH ELECTRICITY ACCOUNTS.

In the accounts of the Edinburgh electricity department for the year ended May 15, 1905, the total expenditure on capital account is given as £897,298. The following are abstracts of the revenue account, balance-sheet, etc.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
To generation of electricity	25,367	6	5
Distribution of electricity	4,341	6	2
Attending and repairs to public lamps	3,959	18	0
Rents, rates, and taxes	8,018	3	5
Management expenses, salaries, etc.	5,053	15	3
Miscellaneous expenses	658	7	2
	47,398	16	5
Surplus carried to net revenue account	71,471	18	8
	£118,870	15	1

Cr. Income.	£	s.	d.
By sale of current for lighting and power	107,792	8	5
Public lighting	11,000	16	5
Meter rents	53	7	5
Rents of properties	8	3	1
Miscellaneous receipts	15	19	9
	£118,870	15	1

BALANCE-SHEET.

Dr. Liabilities.	£	s.	d.
Sundry creditors for outstanding accounts	1,785	11	9
Reserve fund	252,728	6	6
	£254,513	18	3

Cr. Assets.	£	s.	d.
Balance at debit of capital account	172,713	6	8
Bank balance	3,657	2	4
Stores on hand	3,350	1	2
Advance to resident engineer	50	0	0
Sundry debtors	15,871	6	6
Reserve fund investment	58,872	1	7
	£254,513	18	3

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T.U.		12,845,465
Quantity sold: Private lighting	7,543,739	
Motor power	2,705,259	11,648,501
Arc lamps	1,400,503	
Quantity used on works		559,963
Quantity unaccounted for		637,001

BERMONDSEY ELECTRICITY ACCOUNTS.

The accounts of the Bermondsey electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £106,668. Appended are abstracts of the revenue account, balance-sheet, etc.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
To generation of electricity	3,177	10	1
Repairs, etc., of buildings and plant	507	18	3
Repairs to artesian well	347	6	1
Distribution of electricity	464	15	3
Attending and repairs to public lamps	1,244	0	2
Rents, rates, taxes, and insurances	473	18	3
Management expenses, salaries, etc.	1,128	0	2
Law and parliamentary charges	7	3	2
Special charges	375	15	7
	7,726	7	0
Amount carried to net revenue account	4,276	17	3
Balance to provide for bad debts	25	15	7
	£12,029	19	10

Cr. Income.	£	s.	d.
By sale of current per meter, less rebates	7,052	2	8
Charging batteries	0	7	6
Rental of meters and other apparatus	137	3	2
Public lighting	4,747	13	8
Sale and repairs of lamps, etc.	37	11	6
Water supplied to baths and destructor	54	19	4
Miscellaneous receipts	0	2	0
	£12,029	19	10

BALANCE-SHEET.

Dr. Liabilities.	£	s.	d.
Capital account—outstanding on loan account	97,542	14	10
Sundry creditors	1,716	8	11
Balance at credit of net revenue account	1,000	0	0
Balance to provide for bad debts	26	15	7
Reserve fund account	503	0	10
Sale of materials and laying and altering mains	1,112	10	1
Treasurer—balance overdrawn	9,274	7	1
	£111,175	17	4

Cr. Assets.	£	s.	d.
Capital account—amount expended less depreciation	106,181	10	7
Stores on hand	1,586	0	1
Sundry debtors for current supplied, etc.	2,909	1	2
Securities held (cost price)	499	5	6
	£111,175	17	4

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T.U.		1,039,505
Quantity sold: Private consumers by meter	649,918	
Public lamps	282,185	932,103
Quantity used on works		69,939
Total quantity accounted for		1,002,042
Quantity unaccounted for		37,460
Maximum supply demanded (kilowatts)		538

Number of public lamps: 168 arcs, 336 arc-incandescents, 200 side street.

WOOD PAVING.

No, there is no idea at this time of day of dealing with wood as against stone, or soft wood as against hard wood. These things have been treated *ad nauseam*. Mr. Green, however, has, by his paper read before the Tramways and Light Railways Association, brought the matter of material for roadways again into notice. Mr. Green, of course, knows his subject—that is his business—hence whatever he may say upon the question of the use of various materials, and of hard woods especially, is worth considering in the connection of their use for the making of roadway surfaces. We may, however, quote one paragraph of Mr. Green's paper, even though it be lengthy, and with his remarks we agree:

Essentials of Good Paving for Cities.—The essentials of a perfect paving may be summed up as follows: it must have a perfectly sound foundation; it must be non-absorbent; it must have a smooth and even surface, offering the least resistance to traction; non-slippery, noiseless, durable; not subject to expansion or contraction; easily cleaned and repaired; and, lastly, we may say it should have a pleasing appearance. This is, of course, an ideal which has never yet been attained, and I do not suppose ever will be. Paving may be said to be "what it is—where it is"; by which I mean that the value of any form of paving is according to its suitability to the locality in which it is used, and to the traffic which has to pass over it. It would be entirely out of place, for instance, to lay down a road of soft-wood paving in the vicinity of docks where a very heavy and continuous traffic has to pass over it, and to condemn it as a bad form of paving because it wore out so rapidly. In the selection of a paving material every condition to which it has to be subjected must be thoroughly considered. There are few, if any, materials which are adaptable to every purpose, and there is no standardisation of paving materials by which one can make a selection for a special set of conditions; choice must be decided by experience. I shall hope to be able to do something in this paper towards simplifying the problem which every surveyor is confronted with, and, as an appendix to the list of essentials of a paving already given, a table is given below which shows the comparative qualifications of different paving materials now on the market. This table appeared in an official publication issued from the office of the Agent-General for Western Australia some three years ago:

	First.	Second.	Third.
Durability	Hard wood	Asphalt	Soft wood
Economy	Hard wood	Asphalt	Soft wood
Hygiene	Asphalt	Hard wood	Soft wood
Quietness	Soft wood	Hard wood	Asphalt
Safety	Wood	Asphalt	—
Traction resistance	Asphalt	Wood	—
Ease of cleansing	Asphalt	Hard wood	Soft wood
Ease of repair	Asphalt	Wood	—

In the consideration of the question of noise, it seems to have escaped most writers that noise is caused by at least two factors: (1) the street surface, (2) the traffic on that surface. Now, the various surveyors have done something for the street surfaces, but who has agitated against the infernal rap, rap of iron-shod hoofs, or the rattle, rumble of vehicles of antiquated descriptions and haphazard make Is noise bad for health or business and quietude an advantage? If so, work upon a modification of both factors till the minimum noise is obtained. Why expect everything from the use of a certain material for the road wearable surface? The idea is really preposterous, but hitherto criticism has been concentrated on the roadmakers, the roadmaking, and the materials used. Our point in referring to this question just now is quite a different one. For some years a solitary few have been advocating a different method of laying the wood blocks. With one exception the views expressed found no favour in this country, but singular to say, they have largely been followed abroad·

Digitized by Google

Take one example: with tramways it is always the case that ruts wear in the road alongside the rails. Our method of paving is by parallel series of header courses abutting on the rail and kerb, with, of course, the necessary arrangement for breaking joint. When a rut along the rail sides becomes troublesome, repair is expensive and also troublesome. As we have long advocated, and as followed of late abroad, a stretcher course of blocks is laid alongside the rails, with parallel header courses abutting on these. We have in some cases seen two stretcher courses parallel to the rails, with header courses between. Another innovation to our ordinary system now becoming almost universal in certain districts in Germany is that the header courses are not at right angles to the kerb, but at an angle of forty-five, the apex being in the centre of the road. These innovations may have no value in practice. We think they are an improvement upon our ordinary methods, and, so thinking, call attention to them, knowing that if they are not advocated by the more eminent consulting engineers and insisted upon in their works it will be long, very long, before the ordinary councillor is brought to vote for change.

FORTHCOMING EVENTS

FRIDAY, DEC. 1.

Institution of Civil Engineers (Students' Section).—A 8 p.m., "An Installation for the Bacterial Treatment of Sewage at Neath," by Mr. W. L. Jenkins.

North-East Coast Institution of Engineers and Shipbuilders.—At 7 p.m., annual dinner.

MONDAY, DEC. 4.

Society of Arts.—At 8 p.m., "The Measurement of High-Frequency Currents and Electric Waves," by Dr. J. A. Fleming, D.Sc., F.R.S. (in continuation of previous courses on "Electric Oscillations and Electric Waves" and on "Hertzian Wave Telegraphy"). (Lecture II.)

TUESDAY, DEC. 5.

Institution of Civil Engineers.—At 8 p.m., "The Steam-Turbine," by the Right Hon. C. A. Parsons and Mr. G. G. Stonier.

WEDNESDAY, DEC. 6.

Society of Arts.—At 8 p.m., "The Manufacture of Sugar from British-Grown Beet," by Mr. Sigmund Stein.

Institution of Civil Engineers.—Students' visit to the Erith slipway of Messrs. W. Cory and Son. (Train from Charing Cross Station to Erith, 1.16 p.m.)

Automobile Club.—At 7.30 p.m., founders' dinner (at 119, Piccadilly).

THURSDAY, DEC. 7.

Society of Arts.—At 4.30 p.m., "The Partition of Bengal," by Sir James Bourdillon, K.C.S.I.

Rontgen Society.—At 8.15 p.m., "The Spontaneous Action of Radium and other Bodies on Gelatine Media," by Mr. J. Butler Burke, M.A.

Institution of Electrical Engineers.—At 8 p.m., "The Charing Cross Co.'s City of London Works," by Mr. W. H. Patchell.

Civil and Mechanical Engineers' Society.—At 8 p.m., "Concrete Mixers," by Dr. J. S. Owens.

FRIDAY, DEC. 8.

Institution of Electrical Engineers (Manchester Local Section).—At 7.30 p.m., "Electrification of Existing Steam Railways," by Mr. W. H. M. Parr.

Northampton Institute.—At 8 p.m., Sir William Preece, K.C.B., F.R.S., delivers the prizes at the annual prize distribution and conversazione.

Institution of Electrical Engineers.—At. 7 p.m., annual dinner at Hotel Cecil.

Institution of Electrical Engineers (Manchester Local Section).—Dec. 12, at 7.30 p.m., "Street-Lighting," by Mr. Haydn Harrison.

Association of Engineers-in-Charge.—Dec. 13, at 8 p.m., "High-Pressure Gas Illumination," by Mr. J. W. Blakey (at St. Bride's Institute).

Tramways and Light Railways Association.—Dec. 14, at 3 p.m., visit to Lots-road Power station. At 8 p.m., "Improvements in Trucks," by Mr. E. Cook.

Physical Society.—Dec. 15, from 7 till 10 p.m., exhibition of electrical, optical, and other physical apparatus at South Kensington Museum.

Junior Institution of Engineers.—Dec. 16, visit to Messrs. Johnson and Phillips's works at Charlton.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

COMPENSATION.

SIR,—About six months ago we had rather a serious accident to a pedestrian, caused by a broken wire, and which is now causing some trouble to the Council in the matter of compensation. A bare wire had been run for about one mile carrying 1,000 volts to a transformer, and was protected by double-pole fuse where it branched off the insulated wire. In a very heavy wind and rain storm the wire broke, the live end coming to the ground and blowing the fuse, which in ordinary cases would have made it safe for anybody to catch hold of. But, owing to the dead end having blown over the top of a series circuit and hanging down in a loop, the current was directed to earth with a live wire, and this person caught hold of it with both hands and was thrown to the ground, where he laid for about five minutes still holding on to the bare wires till released by chopping the wire with an axe. Of course, the man was very severely burnt, and had received such a shock that he was removed to the hospital in almost a state of collapse. The contention is that the Council is liable for having bare wires running overhead carrying a dangerous voltage. The Council contend that as the wires were protected by safety fuses, and it was an act of God that caused the dead wire to blow over the live wire and again become alive itself, they are not responsible for the accident, and that there is no law existing that prohibits bare wires to be run. I shall be glad if you will find room for this in your valuable paper, so that others may give their experiences of like accidents—if, indeed, such a one has ever occurred before.—Yours, etc., D. H. S.

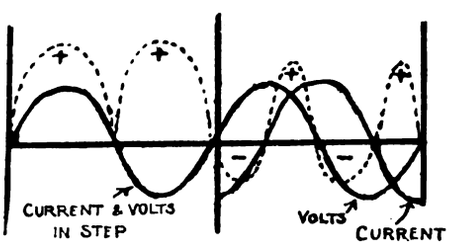
Penrith, N.S.W., Oct. 23, 1905.

ANSWER TO QUESTION No. 820.

SIR,—There are two errors in the answer to Question No. 820 in the supplement to the *Electrical Engineer* of Nov. 10, both evidently being slips made by the authors. May I point these out, as they are likely to prove confusing to the writer of Question No. 820?

1. In Mr. E. R. Alexander's answer the assumption at the end, "if two motors can be found to do the same work, taking the same current at the same pressure, one having a lower power factor than the other," is, of course, impossible.

2. The diagram in the answer of "F. B. M."—the total power in both cases as shown is zero. The diagram should be thus:



The (+) and (−) signs refer to the power as shown by dotted curves.—Yours, etc., P. WEIL.

85, South-side, Clapham Common, S.W.,
Nov. 12, 1905.

BELFAST ELECTRIC TRAMWAYS.

The inauguration of the new electric tramway system in Belfast took place on Wednesday, the 29th inst., Belfast being practically the last of the large provincial towns in the kingdom to adopt electric traction. The contract for the whole equipment was given to Messrs. J. G. White and Co., London, who commenced operations in February last, and were required to have the whole system completed in seven months. Thus it was expected that the inauguration would take place in September, but various causes have delayed it. During the first few weeks of work strikes

Digitized by Google

occurred of the labourers on the permanent-way work, and when September arrived it was found that the pump-house could not be completed in time. This is a portion of the work outside the contract. For some reason, delivery of the condensing plant has not yet been completed, otherwise the whole equipment is practically completed. There are three 1,000-kw. units in the generating station, two of which are sufficient for the work, so that one unit is available as a stand-by.

On Tuesday, the 28th inst, the representatives of the Board of Trade (Major Pringle, R.E, and Mr. A. P. Trotter) commenced their official inspection of the new system. Mr. Trotter, who had to deal with the electrical equipment, completed his inspection, travelling along the various routes in one of the cars which had been previously used in the horse traction service, and was locally converted and equipped for the new electric service. It is understood that the whole of the overhead equipment is satisfactory; as a matter of fact, nearly all the telephone wires contiguous to the track have been removed or disposed underground, so that there is almost an entire absence of guard wire in the overhead equipment. Major Pringle hopes to finish his inspection on Friday, Dec. 1, and in the meantime is so far satisfied that the inauguration of the electric service was possible on the 29th inst. on some of the principal routes.

The inauguration took place at noon. Six of the new cars were held in readiness on the west side of Donegall-square, the first and last cars being elaborately decorated with wreaths and festoons of flowers, trailing smilax, and potted plants. The Lord Mayor of Belfast (Sir Daniel Dixon, Bart, who is also member of Parliament for one of the divisions of the city, and is chairman of the Tramways Committee) was in the first car, and it, together with the other five, were filled by the members of the Council of the county borough, many influential citizens, and the representatives of the contractors. Punctually to the hour named, the cars started amid the cheers of thousands of spectators who had crowded the ample accommodation of Donegall-square and its immediate vicinity.

The first journey taken was over the Malone-road route as far as Cranmore Park and back, then in quick succession journeys were made over the routes of the Ormeau and Lisburn roads, the trips concluding in front of the Ulster Hall at 1.10 p.m. The six cars ran about 50 yards apart, and their speed was a revelation to the many spectators who lined the routes, and who were for the most part only familiar with the speeds of the old horse-car service. The journey along the Lisburn-road was timed at exactly seven minutes, a figure which compares very favourably with the 20 minutes taken by the horse cars.

The entire journey was absolutely devoid of untoward incident—a fact which is much to the credit of the various contractors and all others concerned. There was an entire absence of vibration or pitching of the cars even at the highest speeds, which must have been over 16 miles an hour, and the smoothness of running was unbroken by any jar or other evidence of unsatisfactory permanent-way construction. No attempt was made to set the overhead points by means of the trolley pole, as the necessary construction for this purpose is not yet completed; but apart from this, the overhead portion of the system worked perfectly, and on the whole journey of the six cars only once was the trolley wheel seen to leave the wire, though high speeds were attained.

When the trips were completed, the passengers were entertained with light refreshments in the Ulster Hall by the Lord Mayor. The toast of the "The King" was first given by the Lord Mayor, Sir Daniel Dixon, who then proposed "Success to the New Electric Tramways." In a very few words he drew attention to the fact that the whole of the new system had been undertaken and completed by the contractors in 10 months, and that during that time the horse traction had been but little disorganised. To provide the Belfast people with such a splendid and successful system of electric tramways in that short time reflected the greatest credit on Messrs. J. G. White and the sub-contractors, while it was evidence of the whole-hearted efforts of Mr. M'Cowen (the borough electrical engineer) and his able assistants. This toast was followed by that of "The Health of the Lord Mayor," proposed by Councillor Wm. Harper, vice-chairman of the Tramways Committee. Councillor Harper spoke in felicitous terms of the zeal of the Lord Mayor as chairman of the Tramways Committee, and said that the people of Belfast, so long denied the conveniences of electric traction, would still be without them in 1905 had it not been for the efforts of Sir Daniel Dixon and the diplomatic methods he adopted with all parties to bring the electric tramway system to a successful issue.

The toast being received with applause, the proceedings then terminated.

MANCHESTER SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

Chairman's Address.

BY S. L. PEARCE, M I E E.

(Continued from page 745.)

Turning to the application of electrical power for industrial purposes, we find that very considerable progress has been made during the last year. A cheap supply of electrical energy for London, to which reference will be made later, has been one of the most striking events in electrical circles, and in other parts of the country four power companies—viz., the Yorkshire Electric Power Company, the Lancashire Electric Power Company, the Clyde Valley Electric Power Company, and the Fife Electric Power Company—have commenced operations, and others will shortly follow. It is noteworthy that of the four new companies the three former are employing three-phase systems operating at 10 000 and 11,000 volts, and the latter a two-phase system at 3,000 volts. Nor have the larger municipalities been behind-hand in the development of a power load at cheap rates, assisted by such means as the hiring-out system of motors and the "restricted hours' supply" system at very low rates. It may, perhaps, be of some interest to state that in this city at the present time there is in use some 11,000 h.p. in motors, and the power sales for last year show an increase of 75 per cent. over the preceding year. Industrial establishments possessing their own independent steam installations are naturally chary of making changes, but records go to show that as the more economical advantages of electrical driving are appreciated, so will the gradual supplanting of steam plant be accomplished. This is more particularly noticeable in the case of the iron, steel, and shipbuilding industries, and for colliery and mining work, all of which show a marked partiality for electrical power, which is evidenced by its extensive adoption at the many centres of the North-East Coast, on the Clyde, in South Wales, and in the counties of Lancashire and Yorkshire.

The adoption of electrical transmission of power for textile factories is a problem that more clearly concerns us in this part of the country, but on account of the more favourable conditions for operating with steam plants little progress has been made. This is certainly a matter for some considerable surprise in the light of data obtainable from the States and the Continent, where textile factories have adopted electrical driving extensively. On the other hand, it must be admitted that if it be possible for a cotton mill equipped with steam plant to operate at a total cost not exceeding £2. 10s. per indicated horse-power per annum, it would be difficult from the point of view of economy to show much better figures than these, and some very cogent reasons in favour of electrical driving must be advanced before millowners can be expected to adopt it. Competition in the production of marketable articles is already keen, and, realising that the advantage will be to those who can produce at the lowest cost, we see how important is the question of cheap power to the British manufacturers, and how necessary it is that by every means the production and transmission of electrical power should be cheapened. For large industrial installations there is a tendency to adopt three-phase motors where a three-phase supply is available, and where a variable speed is not required. A comparison between direct-current and three-phase induction motors shows that, so far as efficiency is concerned, there is little to choose between the two types; for motors up to 40 h.p. the advantage rests with the three-phase induction motor, and above this output with the direct-current type. The difference in weight is, however, very marked in favour of the former, and the low maintenance costs and general freedom from running troubles are also strong points in favour of its adoption.

Hauling gears up to 500 h.p. by induction motors are now becoming common in collieries. Continental practice has done much to perfect winding gears, and there is little doubt that

Digitized by Google

the displacement of older steam plants by motors is gradually being brought about. Electric cranes of high lifting capacity are being built in increasing numbers, a notable instance of this class of work being the 150-ton revolving pillar crane at the Dublin Docks. The past year has evidenced a testimony on the part of manufacturers to produce variable-speed motors without double-wound armatures, and without the need for multiple voltage winding. The development of this class of motor for continuous currents will, doubtless, popularise the use of motors for individual drive of machine tools where wide ranges of speed are desired and where complicated gearing is to be avoided.

The question of furnishing energy for large consumers from a public supply or from isolated independent plants is one to which considerable attention has been given. Broadly speaking, it may be stated that unless an exceptional load factor can be shown—viz., something in the neighbourhood of 40 to 50 per cent.—it will be more advantageous for the consumer to obtain energy from supply mains. Capital cost of plant will be saved, space that would be occupied by generating plant can be otherwise utilised, a supply is always available, thereby facilitating overtime arrangements, and antiquation and depreciation of plant become minor considerations. For transmission lines the use of bare copper wires has been sanctioned in the case of three or four of the power companies, and incidentally it may be stated in passing that one of these—viz., the North Wales—avails itself of the use of water power, and will, therefore, form one of the very few examples of hydro-electric installations in this country. It is also of interest to note that this company, together with the Gloucestershire Power Company, were the first to obtain parliamentary powers to use overhead bare conductors. We see very few overhead mains in this country, and until recently the Board of Trade would only sanction their use for special purposes at comparatively low pressures; now, however, they permit bare overhead work for high-pressure transmission lines. Taking a 6,000-volt transmission line, the cost of running three-phase mains of any given section overhead would be approximately one-half of an underground main of the same section. For a 12,000-volt transmission line the proportion would be, roughly, one-third only. It is evident, therefore, that this factor will have an important bearing on capital costs and the question of cheap supply of power. Long-distance power transmission work with its corollary of extra high voltages has not made much advance in this country, up to the present the highest pressure employed being 11,000 volts. Although hard-drawn copper is still most generally used for bare conductors, the recent rise and maintenance of very high prices for raw copper due to restricted sources of supply and the financial operation of capitalists will undoubtedly help to advance the claims of aluminium. For a given conductivity the weight of the latter is only half that of copper, and its tensile strength for a given conductivity is about 75 per cent. of a copper line. Owing to the weight per foot of wire being reduced some 50 per cent. in the case of aluminium, it is possible to use much longer spans. At present prices of copper the above considerations mean that it would be cheaper to use aluminium.

Although the last two or three years have witnessed a considerable reduction in the cost of production of electrical power on a large scale, electrical engineers should not be unmindful of the fact that there is at the present time an increasing competition for the cheap supply of power for smaller or isolated plants. For plants using up to 200 b.h.p. to 300 b.h.p. suction-gas producers and Diesel engines will prove keen rivals owing to their low fuel consumption. The cost of the latter per brake horse-power hour in the case of a suction producer has been stated to be only one-half that of Mond gas at, say, 2d. per 1,000 cubic feet. This saving will, however, be discounted in the cost of the producers if the plant is subject to a variable load or run for considerable periods much below full load. The difficulty is to obtain reliable and accurate data with respect to this latter point, makers invariably giving the full-load results only. It will be conceded that where it is necessary and convenient to transmit all the power required from one point in any works, and under conditions that call for a steady load, the suction-gas plant may be the more economical. But do conditions such as these generally obtain in modern factories, and can any fair comparison be drawn in this form between electrical driving and gas plants? Modern users of electrical power find it more economical and convenient to dispose of their power at certain specified points so as to eliminate transmission losses and secure independent running for the various parts of their factories. If this be granted, then the only fair comparison to be made is between a motor-driven factory taking a public supply of energy and a similarly equipped motor-driven factory taking a supply from its own private gas plant, and it can be shown then that the costs of production do not widely differ. But these are not the only considerations to be taken into account. There are the questions of ground space for the private plant, the expenditure of relatively large sums on same, the ability to run any particular portion of a works on overtime without running the whole generating station, which, in the case of a suction plant running at anything under half load, would certainly be the reverse of economical. These and other points are worthy of consideration, and whilst there may be particular conditions under which the gas plant will prove the most economical, the many advantages of electrical power, coupled with the low rates at which it can now be obtained, should continue to attract all the largest power users.

A steady growth in electric traction work can still be chronicled. For tramways, extensions are proceeding on pretty well defined lines. The trolley wire system is still by far the most extensively used. Conduits are confined more or less to portions of London and Bournemouth, and the Lorain surface-contact system to Wolverhampton. Examples of the "Dolter" and "G. B." systems of surface contacts are, however, being installed at Torquay and Lincoln respectively. Some idea of the extent to which electric tramways and light railways have developed may be gathered from recent published returns, which go to show that the increase in capital invested in these undertakings for the last recorded 12 months over the preceding period is represented by no less a sum than £25,000,000, and the total capital invested in electric traction stood at the end of 1904 at the figure of £107,000,000. The series-parallel system of control up to recently was the only one adopted successfully, but considerable developments have taken place of late in the introduction of systems embodying the principle of "regenerative control." With the series motor, the maintenance of a constant speed over varying grades is attained by the controller with the expenditure of a certain waste of energy in resistances. To obtain an electrical braking effect, the motor is cut off from the line and short-circuited through resistances. The property possessed by a shunt motor of automatically producing a regenerative braking action whenever the normal speed was exceeded, together with that of automatic speed regulation, enabling the car to maintain a fairly constant speed without the use of the controller, would appear as strong points in favour of the adoption of shunt motors for traction work. The most serious objection to their use was the difficulty of insulating the field coils, which had to bear the full line pressure, and in getting on the desired number of turns of fine wire with good insulation. Other objections were the possibility of sudden rises in pressure should the load be suddenly removed when running at full speed with a constant field excitation, the greater liability to sparking, and the danger of a disruption of the field circuit. These objections to the use of simple shunt motors appear to have been largely surmounted in the types adopted in the systems of regenerative control now being introduced. The chief claims of the latter may be briefly stated to be as follows as far as the cars are concerned: economy of power consumption, varying from 7½ per cent. to 40 per cent., dependent on the nature of the route, or on an average 25 per cent. due to the motors returning energy to the line; automatic braking, due to the regenerative action of the motors. The whole of the speed regulation is effected on the shunt field between minimum and maximum speeds. Series field windings are also introduced as a means of further control in cases of emergency. Another system in introducing this principle of regenerative control adopts series motors when running and accelerating, and compound generators when regenerating. To accomplish this without having idle copper in the form of the series windings on the fields at any time, the shunt windings are arranged to be sub-divided and grouped in parallel and used as series windings.

It may be taken that the possibility of economising expenditure both upon energy and upon wheels and brakes by the use of the "regenerative principle" has been fairly clearly demonstrated, these savings being proportionate according to the undulations of the routes served. Further, the variations in the power taken by each car are not so great as with the series-parallel system, and, therefore, a better load factor will be obtained at the power station from a system operated "regeneratively." The outstanding matters on which engineers do not appear at present to be agreed are reliability, maintenance, and whether such systems are as favourable for "acceleration" or hill-climbing capabilities as the "series-parallel." To these questions, the obtaining of accurate and, as far as possible, independent data from repeated trials under strict commercial conditions will alone supply the answer. For existing tramway undertakings to adopt the regenerative system would entail very considerable capital expenditure, and if, in addition to the modified form of controllers new motors were also required, the cost would seriously offset the economies to be gained. For new undertakings, especially where the gradients are severe, it would appear that it has paramount claims for recognition.

It may be noted, in passing, that the principle of regenerative control is more easily capable of application to the induction motor, and most of the three-phase mountain railways on the Continent are so arranged that the energy of the trains on descending should be returned to the line. The practical application of the old principle of regenerative action to the direct-current motor, however, marks a new departure in the tramway world, and as such is of interest to all electrical engineers. The conversion to electric traction of the Metropolitan

Digitized by Google

Underground Railways in London has been one of the outstanding features of this branch of the industry during the last year, and numerous tube lines are in course of construction, all of which work has up to the present been carried out on the composite system, first initiated in this country by the Central London Railway Company, employing three-phase currents in the line transmission and direct current on the motors. This system may be good enough for tube and suburban lines, but most engineers are agreed that it will not solve the problem of main-line working, and it is towards the solution of this latter problem that more than ordinary attention has been given lately. The alternative to the composite system hitherto adopted, but of which there is no example in this country—viz., three-phase currents stepped down from the pressure of the transmission lines and supplied to three-phase motors—has given satisfactory results in a good many places on the Continent, notably on the Burgdorf-Thurn, Valtellina, and Berlin-Zossen lines, under the conditions to which it has been applied, but it would not meet all the essential requirements for the electrification of main-line railways. The impetus to this latter movement was unquestionably given by Finzi's experiments in Milan in 1903, and since that date there has been considerable activity displayed in Germany and the States towards the development of the single-phase commutator motor, which in its perfected form is expected to greatly help forward the solution of the problem of main-line working. This theory appears also to have appealed to one or two of the British manufacturing firms who are now tackling the problem on similar lines.

The question of a standard railway motor is of the utmost importance, and unquestioned advantages would result from a single-phase system as regards chiefly economy, reliability, and simplicity of the track construction and rolling-stock. As far as the motor is concerned, the essential qualifications may be taken as: (1) ability to give a large starting effort; (2) the power to vary the speed through wide limits; and (3) they should return energy to the line when coasting or stopping. Recent developments of the series compensated single-phase motors have made them equal to direct-current motors as far as the first point is concerned, and by the introduction of a transformer between line and motor, with variable ratio of transformation, thus giving a means of regulation between fairly wide limits without serious waste, the second requirement is satisfied. For long lines with no severe gradients and few stops the third point is not of great importance, but for short suburban lines it is of considerable moment, and up to the present this condition is not met by the single-phase motor. The Oerlikon system of a combination of the direct-current locomotive with the motor-generator sub-station carried by the locomotive is not one that is likely to commend itself as a final solution of efficient single-phase working, although it should be remembered that the ideal system will be one that admits of different kinds of application as far as the motors are concerned to suit the different kinds of service over the line. Although the work which has been done with one-phase commutator motors has been largely of an experimental nature, and on experimental lines, the present year has seen the putting into operation of the first single-phase electric railway in the States, and it is understood that one of the English railway companies has decided on applying the same system to a portion of one of their suburban lines. On the American line referred to the motors are of the series type, working from a trolley line fed at 3,300 volts, and at a low periodicity. An auto-transformer carried on the car reduces the trolley line voltage to that for which the motors are wound, and control is obtained by the use of an induction regulator of a type with which we are familar in this country, in which the secondary of the regulator is arranged to oppose or assist the voltage of the main auto-transformer. When the problem of electrifying the main lines in this country comes to be undertaken, it will be desirable to place the generating stations as close as possible to the natural sources of energy—viz., the coal-fields—providing the other conditions governing the selection of suitable sites for power stations are reasonably complied with, therefore to make the supply commercially possible, high pressures must be adopted for the transmission lines. Employing an alternating-current system does away with the serious conversion losses to direct current. The number of static transformer stations could be more economically increased than would be the case with rotary transformer sub-stations, thus giving a better distribution along the track. Further, the alternating-current system admits of a higher pressure on the overhead lines than with the direct-current system, and any such high pressure is capable of reduction by transforming units carried on the train. Simplicity and security of operation is undoubtedly best secured by the use of one overhead line only, and economy of supply to the line is best secured by an alternating-current system.

Although the single-phase system has made very considerable strides during the past year, the advocates of the three-phase system are not prepared to lightly give way. Stress is laid on the fact that the three-phase induction motor is a more mechanical piece of work, and therefore the decreased cost of upkeep for the motor would affect the increased repairs due to the use of a double trolley line. Again, importance is attached to the ability of three-phase motors to return energy to the line in braking and slowing down. The objections are: at least two track conductors are necessary, and there are but two efficient speeds as in the ordinary series-parallel direct-current system at which the motors operate. Whatever may be the outcome of the present developments, whether a standard system applicable to all classes of railway working be evolved, the past year has certainly claimed more attention from engineers for this branch of the industry, and the future is pregnant with great possibilities. Incidentally it may be noted, in passing, the recommendations of the London Traffic Commission bearing on the question of electric traction, and its advocacy of the provision of 50 miles of tramways within the county of London, in addition to several miles of subways, and substantial additions to the existing city and suburban railways. These recommendations, if ever adopted, will provide the electrical industry with a task of furnishing the Metropolis with a transit system equal to any existent. It is interesting, also, to note that the report speaks out with no uncertain voice in favour of electric tramways as against the much-belauded motor 'bus, which should bring consolation to many threatened tramway undertakings.

(*To be continued.*)

A MINE OF INFORMATION.

It is a happy idea on the part of the General Electric Company to collect the numerous catalogues issued by them describing and illustrating their diverse manufactures, and at the end of the year to publish them in book form. The result is a volume which embodies everything electrical, from a terminal screw to a central-station equipment. We have received from the General Electric Company a copy of their 1905-6 edition, and in this vast storehouse of information the buyer and the engineer cannot fail to find something to meet their requirements. Those who have occasion to use and refer to books of such dimensions—for this one extends over 1,500 pages—are often confronted with the difficulty of finding out just what is wanted at a certain time, and, in many cases, a little lack of forethought on the part of the compilers has reduced a really valuable work to a mere chaotic mass of matter. No such description, however, can be applied to the work at present before us, for the excellent system of indexing and classification, and the whole general arrangement, is evidence of the great pains which have been taken to reduce the trouble of reference to such insignificant dimensions that no loss of time need be entailed in the task. The book is divided into 13 different sections, each section representing a different department. The method of arranging the sections is one which enables particulars of all goods likely to be required in connection with one another appearing in close proximity. This comprehensive classification greatly obviates the loss of time consequent upon having to make cross references; thus all plant is kept together in one section, as arc lighting supplies and cables, so that if the price of wall plugs be required it can be speedily obtained by turning to the particular section in which it is classified, where prices of other accessories which are all within the one section can also be seen. Among the new sections the two which will, no doubt, be of considerable interest are "P" and "X." "P" is the electrical plant section, and is devoted to prices and particulars of continuous-current, single and polyphase generators and motors, combined sets, electric cranes, boilers, engines, etc. It extends over 200 pages, and contains, besides illustrations of the manufactures, a number of excellent photographs of central station work carried out by the company. Switchboards are included in Section "X," which is illustrated by a number of plate depicting some of the installations which the company have carried out. What are usually jumbled together and classified under the heading of accessories have in this case been sub-divided and placed in separate sections, so that they can be referred to with facility. The whole of the 13 sections manifest the energy of the company in the very extensive field in the electrical world in which their activities are centred. The sections devoted to large plant and switchboards admirably illustrate the rapid strides which have been made at the Witton Works in the manufacture of this class of apparatus, and give a good idea of the extent of the company's development.

This catalogue must prove of immense value to all engaged in the electrical industry. An enormous amount of time and expense must have been spent upon its production, but we feel assured that all who have one in their possession, and those who must needs be constantly referring thereto, will ever keep the General Electric Company in grateful remembrance for compiling such an indispensable work, and for providing the excellent facilities for enabling them to wend their way with ease through the labyrinth of matter. Our advice to our readers is to write for a copy of the work and judge for themselves as to its value.

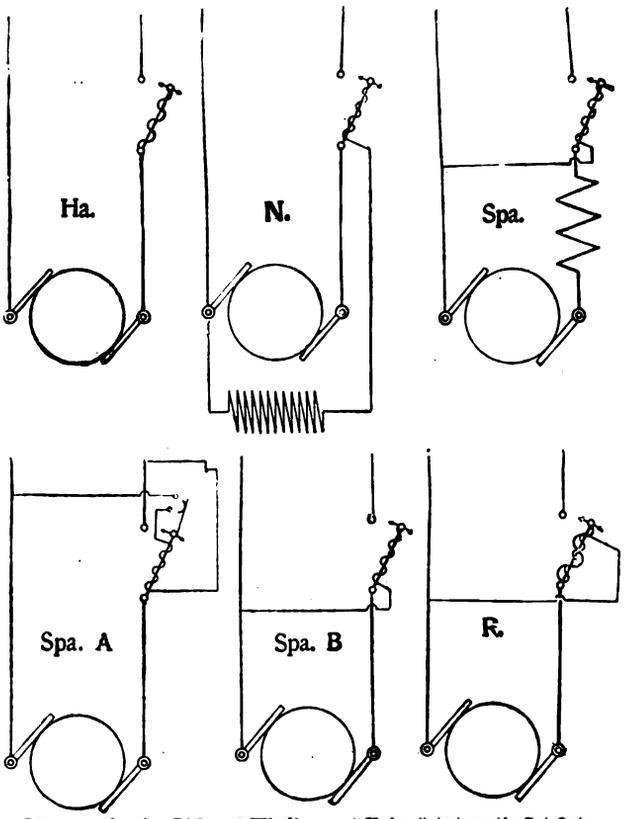
TRADE NOTICES AND NOVELTIES

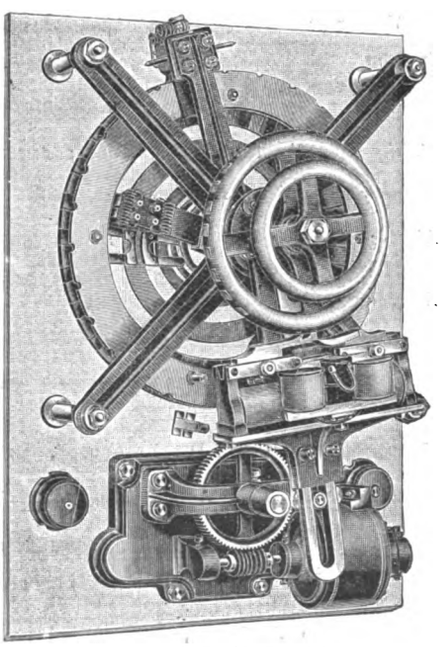
Automatic Circuit Breakers, etc

A list recently issued by the Union Electric Co., Limited, 151, Queen Victoria-street, E.C., deals with direct and alternating



Diagrams showing Different Windings. "Union" Automatic Cut-Outs.

current automatic circuit breakers, suitable both for ordinary motor installations and for the heaviest duties imposed by traction working. The accompanying diagrams illustrate the different methods of operating these cut-outs. The "Ha" series winding is designed to protect a dynamo against reverse current from a battery or other circuit. In the "N" shunt winding type the working coil of the cut-cut is placed in the circuit of a shunt or compound wound motor to disconnect the motor from the mains if current should fail in the circuit, whereas in the "Spa" type it is connected to the terminals of a series motor. Again, in the case of the maximum cut-outs the "Ha" series arrangement is used for protecting a motor or dynamo against overload or a battery against charge or discharge at too high a rate, while the pressure winding "Spa" A with independent circuit is adopted when it is desired to open a circuit at a distance, and the winding "Spa" B for constant load, to open a circuit in which the pressure has exceeded a given maximum. The reverse-current cut-out type "R" can be fitted with supplementary contacts to close another circuit directly it opens, and all sizes are fitted with a magnetic blow-out. The arrangement permitting the fixing of the large circuit breakers behind the switchboard panel is also in accordance with the most recent practice, which is in favour of putting the electrical parts behind the board, and having insulated operating handles in front. The traction type overload cut-outs have a loose handle device of substantial construction, rendering it possible to operate the circuit breaker on a dead short-circuit, without injury either to the apparatus or the operator. On the last page of the list under notice some particulars of cell regulators are given. A novelty is the automatic double regulator, illustrated herewith. This device is eminently suitable for large installations, and such as have to run with a minimum of attention.



Automatic Double Regulator.

Seasonable Novelties.

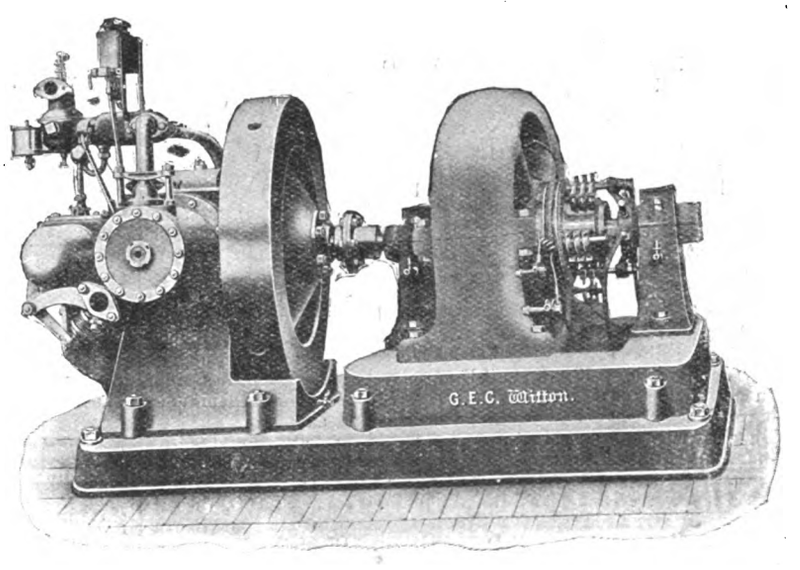
A new catalogue just issued by Messrs. F. Darton and Co., 142, St. John-street, London, E.C. includes illustrations, prices, and particulars of a large variety of seasonable novelties, in the shape of electric motors, small dynamos, gas and oil engines, portable batteries for lighting, telephones, etc. Scientific toys are in great demand just now, especially those of the kind enumerated, so this catalogue should be welcome. We notice also that Messrs. Darton and Co. supply dynamo castings, armature stampings—in fact, all the requisites to enable the enthusiastic amateur to build up machines, and thereby gain additional knowledge.

Magneto Ignition.

Motorists and dealers in motor accessories will be interested in a little pamphlet just issued by the General Electric Company, Limited, which gives full particulars of their new system of magneto ignition (Coate's Patent).

G E C. Electrical Plant.

The "Electrical Plant" catalogue just issued by the General Electric Company, Limited, 71, Queen Victoria-street, E.C., contains particulars of direct-coupled steam, gas, and oil engine generator sets, steam-turbine generator sets, electric lifts and cranes, water-turbines, boilers, steam, gas, and oil engines, etc. It appeals especially to contractors who undertake the installation of self-contained private plants. Some of the generator sets dealt with are exceedingly compact. This is notably the case with regard to the oil-engine set, which we illustrate herewith, by way of example. This set has been designed for small installations, such as for lighting country houses, private yachts, etc., where skilled attendance may not be available, and where safety and reliability are first considerations. The engine is direct-coupled on the same bedplate to a "Witton" continuous-current multipolar-type dynamo, wound for any required voltage. All moving parts of the engine are enclosed, and by the use of a new carburettor, perfect safety is secured.



G.E.C. Oil-Engine Dynamo Set.

Catalogues, etc.

SECRET TELEPHONES.—A little pamphlet which we have received from the Sterling Telephone and Electric Company, 200, Upper Thames-street, E.C., includes prices of their secret intercommunication telephones.

ELECTRICAL DISTRIBUTION APPLIANCES.—The catalogue (1905 edition) of electrical distribution appliances published by Messrs. Callender's Cable and Construction Company, Limited, Hamilton House, Victoria-embankment, London, E.C., is an

Digitized by Google

exceedingly meritorious compilation. It embodies a comprehensive and illustrated price list of designs carefully selected as standards by the company. The plans and sections given could not well be improved upon for clearness, and must have involved the drawing office in a great deal of extra work.

SWITCHES.—Some sheets which we have received from Messrs. A. Seage and Co., Cambridge Works, Hammersmith, London, W., deal with the firm's double-pole switches in cast-iron cases for voltages up to 600.

MOTORS.—The Rhodes Electrical Manufacturing Company, Limited, Bradford, have issued a well-got-up new catalogue of their direct and alternating current motors. The compact form, neat appearance, and other admirable features of these machines are well known to our readers.

WATER MOTORS.—A catalogue recently issued by Messrs. Carrick and Ritchie, Waverley Engineering Works, Edinburgh, illustrates a large variety of turbines, Pelton wheels, and other water motors, incidentally showing what an immense amount of work the firm are doing with this class of machinery for electric lighting and transmission of power.

KNIFE SWITCHES.—Messrs. Ferranti Limited, Hollinwood, Lancashire, have sent us a copy of their catalogue of single-pole, single-throw, quick-break knife switches for currents of 25 to 2,500 amperes; also a catalogue of their double-pole, single-throw, quick-break knife switches for currents of 25 to 1,400 ampere. These switches are of scientific design, and very carefully made.

KORTING GAS-ENGINES.—From Messrs. Mather and Platt, Limited, Salford Ironworks, Manchester, we have a copy of the fourth edition of their two-cycle gas-engine catalogue. The principle of the Körting engine is now well known, but, incidentally, this catalogue records the considerable favour which it has met with in the United Kingdom since Messrs. Mather and Platt, Limited, became licensed manufacturers. Several large plants already installed are described and illustrated.

PRIVATE BILLS AND PROVISIONAL ORDERS.

Further notices have appeared in the *London Gazette* of intended application for private Bills or provisional orders as follows:

Electricity Supply.—Calverley U.D.C. (Extension of Time, etc.), St. Pancras B.C. (Extension of Stations, Refuse Destructor, etc.), London Electric Supply Co. (Extension of Area), North Metropolitan Electric Power Distribution Co. (Wembley), ditto (Edgware), ditto (East Barnet Valley), ditto (Wealdstone). Hackney B.C. (Bethnal Green, Islington, Poplar, Shoreditch, West Ham, Leyton, and Walthamstow), (Kidderminster Electric Lighting and Traction Co. (Stourport and Kidderminster). County of Northampton Electric Traction and Power Co. (Higham Ferrers, Rushden, and Wellingborough), West Cumberland Electric Tramways (Provisions as to Transfer of an Application for Electric Lighting Provisional Orders), Twickenham and Teddington Electric Supply Co. (Twickenham, Hampton, Teddington, Hampton Wick, Sunbury, Feltham, Hanworth, Ashford, Shepperton, Ham, East and West Molesey, Esher, and the Dittons), Brush Electrical Engineering Co. (Workington), ditto (Maryport), Shoreditch and Stepney Borough Councils (Shoreditch, Stepney, Bethnal Green, Bermondsey, Hackney, Islington, Poplar), Camberley Electric Supply Co. (Frimley, Sandhurst, Easthampstead), Market Harborough U.D.C. (Urban District), Hoaforth U.D.C. (Extension of Time, etc.), Hexham and District Electric Supply Co. (Extension), Foots Cray U.D.C. (Extension of Time), West London Electric Undertakers' Association (Power to Westminster Electric Supply, St. James's and Pall Mall Electric Light, Kensington and Knightsbridge Electric Lighting, Notting Hill Electric Lighting, Metropolitan Electric Supply, Chelsea Electricity Supply, and Brompton and Kensington Electricity Supply Companies, and Councils of Hampstead, St. Pancras, Hammersmith, and Fulham, and Central Electric Supply Co. to associate with and supply one another with electricity), Bournemouth and Poole Electricity Supply Co. (Swanage), Mutual Electricity Supply Co. (Henley), ditto (Aylesbury), Newcastle-on-Tyne Electric Supply Co. (Additional Powers), ditto (Castle Ward, Westslade, and Cramlingdon), Farsley U.D.C. (urban district), S. M. H. Tramways Syndicate (Seaham Harbour Urban District), Betwys-y-coed U.D.C. (Urban District), Dorchester Corporation (Extension of Time, etc.), Christy Bros. and Middleton, Chelmsford (Stratton and Bude), Exeter Corporation (Heavitree Urban District), Yardley R.D.C. (Extension of Time, etc.), Slough and Datchet Electric Supply Co. (Extensions), National Provincial Electricity Corporation (Tiverton), Abercarn U.D.C. (Urban District).

Power Companies.—Charing Cross, West-end, and City Electric Supply Co. (London and Essex), L.C.C. (London, Surrey, Middlesex, Kent, Essex), South Metropolitan Electric Supply Co. (supply in bulk), Cumberland Electricity and Power Gas Co. (Workington, Whitehaven, Cockermouth, Maryport, Aspatria, Harrington, Cleator Moor, Egremont, Keswick, Arlecdon and Frizington), London Electrical Supply Co. (Additional Powers to Companies having Statutory Authority for the Supply of Electrical Energy within the Administrative County of London).

Tramways and Railways.—West Cumberland Electric Tramways (Extensions), Wallasey U.D.C. (Extensions), Macclesfield and District Tramways Co. (Borough, Rural District, and neighbourhood), Preston, Chorley, and Horwich Tramways Co. (Extension, etc.), West Yorkshire Tramways Co. (West Riding), Folkestone, Sandgate, and Hythe Tramway Co. (Fotherstone, Sandgate, Cheriton, and Hythe), Ossett Corporation (Extension), Dewsbury Corporation (Extension), Southport and Lytham Tramroad Co. (Extension of Time), Cork Link Railways Co. (Cork), Sandgate and Hythe Electric Co. (to acquire the Sandgate and Hythe Tramway Undertaking of the South Eastern Railway), Hammersmith, City, and North East London Railway Co. (London and Middlesex).

Light Railways.—Mid-Suffolk Light Railway Co. (Financial), Warrington and Northwich Light Railways (Extension of Time), Lindsey Light Railway Syndicate (Fairford and Cirencester), Blackpool and Fylde Light Railway Co. (Extension), Llanelly and District Electric Lighting and Traction Co. (Llanelly and District Light Railways), C. Sinclair and C. E. Straker (Middlesbrough and West Hartlepool Light Railway), Lord Allington and others (Branksome Park and Swanage Light Railway), Middlesex C.C. (County of Middlesex Light Railways), Henry Kaye and others (Clayton West and Darton Light Railway), Bath Electric Tramways (Amendment of their Light Railways Extensions Order), Empire Electric Light and Power Companies (Halesowen Light Railways), Aldershot and Farnborough Light Railway Co. (Amendment).

General Power Bills.—Bacup Corporation (Extension of Electricity Undertaking), Channel Ferry Railway and Quay (Powers to Corporation of Dover as to Supply of Electricity).

NEW COMMITTEES.

The following additional committees have been appointed:

ABERDEEN.—*Gas and Electric Lighting*—Councillor Reilley has been added to the committee in room of ex-Councillor Hutcheon, and Councillor George Allan in place of ex-Councillor Laing, and Dean of Guild Murray takes the place held by the former Dean of Guild, Murray. Councillor Kemp has been reappointed convener. *Tramways*—Councillor Taggart, convener. Councillor Reilley has been added in place of Mr. Hutcheon, and Councillor Glass substituted for Mr. Coutts.

BERMONDSEY.—*Electric Lighting*—Alderman Wilkinson; Councillors Fogden, Bessell, Clark, Moss, Roche, Vesey, Pridmore, Martin, Dean Murphy, and Tovey.

CROYDON.—*Lighting and Electricity*—The committee re-elected Alderman Miller chairman and Councillor Rogers vice-chairman for the current year.

HAMMERSMITH.—*Electricity and Lighting*—Councillor A. Atkinson, chairman; Councillor W. Tomes, vice-chairman; Aldermen Cramp and Pascall; Councillors Bendon, Dr. Bevan, Boarder, E. Davies, Howell, Johnson, May, Neville, Platt, White, and Watkins.

NORTHAMPTON.—*Tramways*—Alderman Wooding, chairman; Councillor Martin, deputy-chairman; Councillors Collier, Green, Martin, Staton, and Webb. The following sub-committees have been appointed—viz: Finance Orders and Claims—the chairman, deputy-chairman, Councillors Collier, Green, and Pearse. Emergency—the chairman, deputy-chairman, and Councillor Green.

NEWPORT.—*Electricity and Tramways*—The Mayor; Alderman Bear and Greenland; Councillors Brown, F. Phillips, Williams, Baker, Abrahamson, Collier, Robjent, Evans, Searles, Parfitt, and Twoomey.

WEST HAM.—*Electric Lighting and Tramways*—The Deputy-Mayor (Councillor Littler); Aldermen Bishop, Byford, Crow, and Ivey; Councillors Baldock, Croot, Cunningham, Dyer, Fielder, Saunders Jacobs, Enos Smith, Spittle, Stoner, and White.

APPOINTMENTS VACANT.

Electrical Engineer, Radcliffe Urban District Council. Salary, £150 to £172 per annum.

Improver. Wages, 10s. per week. Applications to Box 702, *Electrical Engineer* Office.

Wireman for electric light and power plant. Applications to Box 29, *Electrical Engineer* Office.

Representatives for an electrical contracting firm. Applications to Box G 33, *Electrical Engineer* Office.

Laboratory and Workshop Assistant, Battersea Polytechnic, S.W. Commencing salary, 20s. a week.

Switchboard Attendant. Wages, 25s. per week. Applications to Box R P 5, *Electrical Engineer* Office.

Assistant Lecturer and Demonstrator in Electrical Engineering. Leeds University. Salary, £175 a year.

Representative, South Wales district, for the sale of direct and alternating motors. Apply, Box F. Z., *Electrical Engineer* Office.

Shift Engineer, London station. Salary to commence, £2 per week. Applications to Box 574, Sell's Advertising Offices, London, E.C.

Electrical Engineer, colliery in the North of England. Applications to Box Q 11, *Electrical Engineer* Office. See advertisement in last issue.

Junior Charge Engineer. Salary, 30s. per week, rising to 35s. Applications to the Borough Electrical Engineer, 335, High-street, Cheltenham.

LEGAL INTELLIGENCE.

CROYDON TRAMWAYS ARBITRATION.

Certain questions of law in the matter of the arbitration between the British Electric Traction Co. and the Croydon Corporation were down for argument before Mr. Justice Farwell in the Chancery Division last Friday. The arbitration was held by Mr. Parker, and was to settle the form of the lease of the Croydon and District Tramways.

Mr. THOMSON, for the British Electric Traction Co., stated that it had been arranged between counsel that the questions stated by the arbitration should be answered in a certain way.

Mr. WARMINGTON, K.C., for the Corporation, thought it ought to be mentioned that the award was in favour of his client, and as he understood it now the opposition to the award had been withdrawn.

The parties having agreed that the questions stated by the arbitrator should be answered in the negative, his LORDSHIP said the only order he should make was one as to costs.

SWANSEA TELEPHONIC INTERCOMMUNICATION.

National Telephone Co.'s Appeal.

In the Court of Appeal on Saturday last, before Lords Justices Vaughan Williams and Cozens-Hardy, application was made on behalf of the Corporation of Swansea for the appointment of an early date for hearing this appeal. The case was decided some time ago, but execution was stayed on certain terms The action was by the Corporation of Swansea, which had just instituted a telephone system in the borough. The National Telephone Co. had already a system in the borough, and under the Telegraph Act of 1899, on certain conditions and terms, there was a right of intercommunication between the two systems. The action was brought to establish that right. The Corporation succeeded, and the appeal was from the order made in the Court below, and the execution under the order was stayed on certain terms that three exchanges—the two Swansea main exchanges and a local system—will have to be connected, and the interconnection was only to be used for local traffic in each case. The Corporation contracts were all coming to an end, and would have to be renewed in January, and unless they got this made clear before then probably all their subscribers would not take the risk for another year, and subscribe to the National Telephone Co. instead. It was very important from the point of view of the Corporation of Swansea that this should be decided, as far as the Court of Appeal could decide it, before the end of the year.

Their lordships fixed Monday, Dec. 11, for the hearing of the appeal.

BOROUGH OF FULHAM v. NATIONAL CONSTRUCTION CO.

This case was heard in the King's Bench Division before Mr. Justice Bigham on Tuesday, and was an appeal from the award of the arbitrator.

It appeared that in June, 1901, the Fulham Borough Council, the claimants, employed the respondents to put an electrical installation in the Fulham baths. The "non-continuous" system was adopted. On Dec. 23, 1902, two men, named Line and Brown, were using the baths. These baths were separated from each other by slate slabs, about 8ft. high, on the top of which ran an iron tube conducting the electricity. Line was heard screaming, and an attendant found him with his hands on the top of the tube at the top of the slab partition, from which he could not release himself. After the electricity had been switched off, he was taken down, but died shortly afterwards. About an hour later Brown also was found dead in practically similar circumstances. It was admitted that the sections of tubing in these baths were not properly earthed, and that there was a leak in the electric current, and owing to these facts the above accidents resulted. It was contended that this failure to "earth" the tubing was a breach of contract, and that, therefore, the company was liable for the consequent damage to the Fulham Council. This consisted of the sum of £1,100 odd paid by them to the relatives of the two men. The arbitrator found that there was no lack of reasonable care on the part of the respondents in not "earthing" the tubes, having regard to the state of electrical knowledge at the time.

In giving judgment, his LORDSHIP said that the work was carried out under the rules of the Phœnix Fire Office. One of these rules was: "When the system of tubes is employed, the main tube shall be earthed, except in such cases where earthing would not be desirable." In this case the arbitrator to whom the dispute had been referred had held that it would not have been desirable to earth the tube. There had, therefore, been no negligence on the part of the contractor.

Judgment was entered for the electric company.

BRITISH PIONEER ELECTRIC LIGHT AND POWER CO. OF INDIA.

In the Companies' Winding-up Court on Tuesday, before Mr. Justice Buckley, the application for a compulsory order against the British Pioneer Electric Light and Power Co. of India again came on for hearing on the petition of S. T. Biggs and another. The allegation of the petitioners was that there were certain transactions arising out of a concession for a tramway line in Bombay which ought to be looked into by an official receiver.

HIS LORDSHIP, in giving judgment, said the company was incorporated on Feb. 27, 1899, with a capital of £3,000 in £1 shares, on which 15s. had been paid. The operations of the company consisted chiefly in the acquisition of a concession for the construction of an electrical tramway in Bombay and certain dealings and subsequent sale of that concession. The result had been to produce £20,000. There had been returned to the shareholders £6. 15s. per share, or nine times the amount paid up, and there were still some further assets. The company had by special resolutions passed on Nov. 23, and confirmed on Nov. 25, gone into voluntary liquidation. The petition before the Court was presented by the holders of 300 shares and was presented on Nov. 22, the day the special resolutions were passed. The petitioners were two gentlemen named Biggs and Sawyer, who were mortgagees from Mr. Bingham, holding 300 shares, 200 of which had been given for services rendered. Petitioners said that certain transactions which had taken place during the life of the company had given rise to claims against directors of the company for misfeasance. His Lordship reviewed the history of the company and its association with Messrs. Kelmen, and negotiations for the sale of the concession to the Brush Electric Light Co. for £40,000. He said there was no basis for a claim for misfeasance so far as he could see. The petitioners were the holders of only 300 shares, while the holders of the remainder of the 3,000 appeared to oppose the petition. The majority of the shareholders apparently were satisfied at the exceedingly beneficial result of the operations of the Pioneer Co., and they saw nothing to question in the transaction. There did not seem to be anything to investigate. The petitioners were not prejudiced by the voluntary winding-up. They had failed to make out their case, and the petition would be dismissed with costs.

THE RATING OF LIGHT RAILWAYS.

An important point affecting the rating of tramways and light railways came before the City Justices at Wakefield last week, when the Wakefield and District Light Railways Co. were summoned by the Corporation for non-payment of rates, amounting to £40. 2s. 2d.

The light railways company refused payment on the ground that, like ordinary railways, they were liable, under Section 211 of the Public Health Act, 1875, to be rated only at one-fourth of the assessment.

For the Corporation it was contended that a light railway was not a railway within the meaning of the Act, because it was not constructed upon land used only as a railway, but upon public highways repairable by the public at large. In support of this contention the decision of the Swansea Improvement and Tramway Co. *v.* the Swansea Sanitary Authority, 1898, was referred to, in which it was held that the land used by the tramway was not used only as a railway, and therefore was not entitled to be rated at one-fourth. The defendants argued that the provisional order for the making of light railways came within the general enactments, which applied to light railways in the same way as other railways; that, in fact, light railways were exactly in the same position as if constructed under a special Act of Parliament. The company had a right to the exclusive use of the tramlines on the highway, and people had been prosecuted for obstruction; and because of that exclusive use they were entitled to the exemption of three-fourths.

The Bench, after conferring in private, intimated that they decided in favour of the Corporation, and made an order for the rates to be paid in full. They agreed to state a case for the High Court.

PRIVATE TELEPHONES.

A case heard by Judge Woodfall at Westminster on Monday last, in which the Private Wire and Telephone Installation Co., of 5, Palmer-street, Westminster, sued Messrs. Portman and Co., described as commission agents, for £30 rent of private telephone wires.

Plaintiffs' case was that they were the successors and assignees of the Consolidated Telephone Manufacturing Co. In 1901 an agreement was entered into between that company and the defendants, under which private telephone wires were constructed between various offices occupied by the defendants at 8, John-street, 110, Strand, 97, Regent-street, and 2, Sussex mansions, Maiden-lane. The agreed rental was paid at the usual intervals by the defendants to the Consolidated Telephone Manufacturing Co., and subsequently to the plaintiffs as their successors. In March last, however, defendants refused to pay the rent, and now pleaded that the plaintiffs had not obtained the necessary license for the Postmaster-General for putting up these instruments, and, therefore, there could be no contract.

In reply, plaintiffs admitted that they had not the Postmaster-General's license, but pointed out that in the agreement defendants undertook that these telephone wires should only be used by themselves and their servants, and that consequently it was not necessary to obtain a license from the Postmaster-General.

The hearing was adjourned until Dec. 19.

LLOYD'S v. THE MARCONI INTER-MARINE COMMUNICATION CO.

On Saturday last the case of Lloyd's *v.* the Marconi Inter-Marine Communication Co. was again before Mr. Justice Buckley. The action had been in the list for hearing all last week. On Friday counsel asked for a postponement, as settlement was then in negotiation. On Saturday it was announced that the details had been arranged. The result was proceedings in this and another action would be stayed on terms initialled by the leading counsel.

TRAMCAR COLLISION.

At the Sunderland County Court last Saturday an action was brought against the Sunderland Corporation by Robert Reavley for damages sustained through a collision between a Corporation tramcar and one of plaintiff's wagons. The latter was being driven by a pair

Digitized by Google

of horses along a road along which the Corporation tramcars ran. A coal cart, which was in front, got over the tramlines safely, but when the plaintiff's cart tried to cross, the tramcar dashed into it and overturned it. His Honour Judge O'Connor found for the plaintiff for £25. 2s. 10d.

RECEIVER OF RUBBER COMPANY.

Mr. Justice Buckley has granted an application in the action Oppenheim and others *v.* the British Seamless Rubber Co. for the appointment of a receiver. Mr. Crittle, secretary of the company, was appointed receiver.

ELECTRIC CAR AND STEAM-ROLLER.

Before Judge Addison, K.C., at the Southwark County Court, the London County Council sued Jesse Ellis and Co., road contractors, of Maidstone, to recover compensation for damage to an electric car. The defendants put in a counter-claim for £32. 9s. 11d. for damage to a steam-roller.

The Council's case was that an electric car was proceeding along New Kent-road at eight miles an hour, when one of the defendant's steam-rollers approached it, and just before they met the steam-roller was turned suddenly to its off-side and collided with the tramcar.

The defence was that the steam-roller turned to the off-side to avoid a stationary van when the car was 50 yards off. The car proceeded on its journey, the driver apparently mis-judging his position and collided with the steam-roller, breaking the front of the roller.

The presence of the stationary van in the road was denied by the plaintiffs, and his Honour holding that the steam-roller ought not to have left a position of safety and got into the way of the car, found for the Council on claim and counter-claim for £12. 10s., with costs on the B scale.

THE ELECTRICAL FRAUDS CASE.

The trial of W. Leslie, Alice Norton Cheeseman, George Webber, and Richard T. Rosenberg, who were charged, on 25 counts of an indictment, with conspiracy and with obtaining goods and money from firms of electrical engineers by false pretences to the amount of £30,000, was concluded at the Old Bailey on Saturday last. Leslie and Webber (who was in business as an ironmonger at Putney) had been associated for a considerable period, and the case for the prosecution was that they, in conjunction with the two other accused persons, had conspired to obtain large quantities of electrical fittings with no intention of paying for them. Orders for goods were given wholesale by Webber to the prosecuting firms, it being pretended that the particular class of fittings that were required for immediate delivery for use at the Fulham Theatre, where Leslie was employed, could only be obtained through the "Electrical Accessories Company," of Terminus-chambers, Holborn. This was alleged to have been a bogus company, and used mainly for the purposes of the fraud. In a box in the room occupied by the woman the police found £2,000 in gold and £1,500 worth of jewellery, while at the cloakroom of the railway station, where it had been deposited by Leslie, the police found a box containing £4,000 in gold in bags wrapped in some old clothes. It was stated that there was still a sum of £7,450 in Bank of England notes, part proceeds of the frauds, which the police were unable to trace.

The jury found Leslie, Webber, and Cheeseman guilty generally, and Rosenberg guilty of conspiring only, with a recommendation to mercy.

The Recorder sentenced Webber and Leslie each to five years' penal servitude, Rosenberg to nine months' hard labour, and the woman to 12 months' imprisonment in the second division. He also made an order of restitution from the £6,000 found in Leslie's possession on arrest to the amount of the cheques mentioned in the indictment.

COMPANIES' MEETINGS AND REPORTS

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL.

An extraordinary general meeting of this Company was held last week at Winchester House, E.C. (Mr. John MacFarlan presiding), for the purpose of submitting the following resolutions: "(1) That each of the existing 29,100 issued preference shares of £2 each in the capital of the Company be divided into two fully-paid-up preference shares of £1 each. (2) That 8,500 of the existing preference shares of £2 each in the capital of the Company, part of the 20 900 preference shares which remain unissued, be each divided into two preference shares of £1 each. (3) That the remainining 12,500 shares, being the balance of the said existing 20,900 preference shares of £2 each which remain unissued, shall be and the same are hereby converted from preference shares into ordinary shares, and that each of such 12,500 shares be divided into eight ordinary shares of 5s. each. (4) That the capital of the Company be reduced from £162,981, divided into 75,000 preference shares of £1 each, 62,981 ordinary shares of £1 each, and 100,000 ordinary shares of 5s. each, to £115,745. 5s., divided into 75,000 preference shares of £1 each and 162,981 ordinary shares of 5s. each, and that such reduction be effected by cancelling capital which has been lost or is unrepresented by available assets to the extent of 15s. per share upon each of the 62,981 ordinary shares of £1 each, which have been issued and are now outstanding and are credited as fully paid, and by reducing the nominal amount of the said 62,981 ordinary shares from £1 to 5s. per share. (5) That from and after the confirmation by the Court of the foregoing reduction of capital, the rights of the holders of the preference and ordinary shares respectively shall be varied to the following extent. And it is hereby resolved as follows: (*a*) the net profits of the Company available for distribution as dividend in each year shall, after payment of the preferential dividend of 7 per cent. for that year on the amounts paid up on the preference shares, be applicable to the payment of a dividend of 80 per cent. for that year on the amounts credited as paid up on the ordinary shares, and the surplus only (if any) of such net profits remaining after such payments shall be divided between the holders of the preference and ordinary shares in proportion to the number of shares, whether preference or ordinary, held by them respectively; (*b*) in article No 72 of the articles of association the word 'two' shall be substituted for the word 'five.'"

On the proposition of the Chairman, seconded by Mr. John Heal, the resolutions were carried unanimously.

BARCELONA TRAMWAYS.

An extraordinary general meeting was held on Monday at the offices, Winchester House, Mr. J. B. Concanon presiding, to consider a resolution for winding-up the Company voluntarily.

The CHAIRMAN, in proposing the resolution, reminded the shareholders that the directors promised at the last meeting to take the very earliest opportunity of closing up the sale of the undertaking, and to lose no time in connection with the distribution of the assets. Having that promise in view, the present meeting had been called, but he particularly wished to impress on the shareholders that the resolution would not be binding in any sense until the confirmatory meeting to be held about 16 days hence. The balance of the purchase money (£387,000) was not yet paid over, but it would be received on Dec. 11. They were, therefore, somewhat anticipating in holding the meeting before the money was actually in their hands, but, as he had said, the resolution before the meeting was not in any sense binding, nor would the Company be in liquidation until the confirmatory meeting was held. If the resolution should be confirmed at the latter meeting, the bulk of the money would be at once distributed; in fact, they hoped to get it out the same night. He could not state exactly how much the shareholders would receive, but he could confirm his statement at the last meeting—namely, that the amount would be at least £14. 10s. per share. There were various other items to be considered, such as the valuation of the stocks and the amount they were entitled to receive—£5,000—when the unification of the concessions had been confirmed. Until these sums were received the directors could not state the exact amount per share which would be distributed.

Mr. W. F. HAMILTON, K.C., in seconding the motion, stated that the directors had no intention of going into liquidation until the £387,000 referred to had been received in hard cash, and, therefore, if by any chance the money should not be paid by the 11th prox. and the confirmatory meeting were called for the 13th it would not be held, and another meeting would be convened. The reason the directors were running the matter so fine was that they desired at the earliest opportunity to distribute among the shareholders as much as possible of the assets.

The resolution was unanimously passed.

FRASER AND CHALMERS.

The report of this Company for the year ended June 30 states that the business has been generally satisfactory, and the earnings have been about the same as those of the two preceding years, but the total income has been reduced by the non-receipt of dividends on the holding of preference shares of the Allis-Chalmers Co. The changes in the conditions of trade in the United States as respects certain classes of machinery have necessitated continued large expenses by the Allis-Chalmers Co. in laying down plant for the economical manufacture of electrical machinery, steam-turbines, gas-engines, etc., and the profits of the business have been expended in this outlay. The net earnings are £28 922, after the usual allowance has been made for depreciation of buildings and plant at Erith. Competition for trade in South Africa has been severe, and for the first six months of the year the demand for heavy machinery was small. In the last six months some larger orders were obtained, and trade generally has improved. The progress of the mining industry of South Africa offers prospects of a continued demand for high-class machinery, and the Erith shops are at present well supplied with work both for home and foreign use. Owing to the demand for certain classes of machinery and to special requirements for the lately established manufacture of steam-turbines, it has been necessary to add new buildings and tools to the shops at Erith. These improvements will enlarge the capacity of the works, and should increase the Company's earnings on manufactures. The profit of £28 922 added to the balance brought forward, makes a total of £117,624. The dividend on the preference shares and an interim dividend of 3 per cent. on the ordinary shares absorbed £16,065, and a final dividend of 4 per cent. on the ordinary shares is now proposed, amounting to £15,120, leaving a balance of £86,339 to be carried forward.

MORECAMBE TRAMWAYS.

Mr. O. CARR presided at the annual meeting of shareholders in the Morecambe Tramways Co., and, in moving the adoption of the report, which showed a balance to revenue account of £1,630, said that during the year the horse cars had run 145,000 miles, at a profit of 1·88d. per mile, and 1,212,240 passengers had been carried. The number of fares collected had increased by 11 048. The directors regretted that they could not report any further progress in respect to electrification.

Mr. W. H. PICKLES seconded the motion, which was adopted.

A dividend at the rate of 4 per cent. was declared, an increase of ½ per cent. on last year.

NEW COMPANIES REGISTERED.

Rubber Estates Syndicate (of Brazil), Limited.—Capital, £4,150. Object: to acquire any estates for the production of rubber or otherwise and to carry on the business of planters and producers of rubber and other produce, etc. Registered office: 97, Gresham-street, E.C.

Cartomite and Arborite Syndicate, Limited.—Capital, £3,000. Object: to adopt an agreement with W. Love to manufacture and deal with machines, the subject of the patents therein mentioned, and to carry on the business of engineers, electric light and bell installers, etc. Registered office: 78, Fleet-street, E.C.

Ore Concentration Co. (1905), Limited.—Capital, £250,000. Object: to adopt an agreement with B. C. Hiuman, to acquire and turn to account any inventions for the concentration of minerals and the obtaining or separation of metals from their ores, or for the recovery of values from minerals by electrical or other means.

P. M. Electric Manufacturing Co., Limited.—Capital, £3,000. Object: to carry on the business of manufacturers of and dealers in electrical apparatus, sparking plugs, induction coils, tremblers, and all accessories, parts, or articles used in connection with the electrical portion of motor cars, launches, and omnibuses, and other self-propelled vehicles, manufacturers and vendors of electrical apparatus of any kind, etc.

Stratford-on-Avon Electricity Co., Limited.—Capital, £15,000. Object: to acquire rights conferred upon or belonging to any company, corporation, or person to supply electric light or power in Stratford-on-Avon or elsewhere in the United Kingdom, to adopt an agreement between the Corporation of Stratford-on-Avon of the one part and the Birmingham Installation Co. of the other part, and to carry on in Stratford-on-Avon and elsewhere the business of electrical and general engineers, electricians, manufacturers of and dealers in electrical apparatus, suppliers of electricity for light, heat, power, and otherwise, etc.

Evans's Carburetter and Motor Pump Syndicate, Limited.—Capital, £2,000. Object: to acquire certain patents for inventions relating to (1) new and improved carburetters and vaporisers for internal-combustion engines; (2) to motor pumps; (3) to a compound nozzle for blowing compressed air with a suction principle in combination therewith; (4) to a radiator to be attached to internal-combustion engines for cooling water and for other purposes in connection therewith; to develop, deal with, and turn to account the same or any improvements thereon; to carry on the business of mechanical, electrical, and hydraulic engineers, etc.

Liens Registered.

British Electric Co., Limited (London).—Issue on Oct. 13 of £50 debentures, part of a series created same date, to secure £250, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees.

Hopper and Co., Limited (Electricians, Walthamstow).—£2 900 debentures, created and dated Nov. 9, 1905, charged on the company's undertaking and property, present and future, including uncalled capital, have been registered. No trustees.

Keynsham Electric Light and Power Co., Limited.—Issue on Nov. 9 of £1,104 debentures, part of a series created same date, to secure £1,500, charged on certain land and buildings occupied by the company at Keynsham, Somerset, and the company's undertaking and property, present and future, including uncalled capital, subject to £1,500 first debentures. No trustees.

Electrical Corporation, Limited (London).—A charge on book debts and sums of money due to the corporation and its undertaking and property, present and future, including uncalled capital, dated Oct. 31, 1905, to secure £272 2s. 6d., and further advances up to £800, has been registered. Holders: E. S. Parker and A. H. H. Richardson, both of 52, New Broad-street, E.C.

Buenos Ayres Port and City Tramways, Limited.—A trust deed, dated Oct. 30, 1905, to secure £200,000 debenture stock, created by resolution of Aug. 1, 1905, has been registered. Property charged: a certain concession relating to the construction, etc., of electric tramways in the port and city of Buenos Ayres, and the company's lands and general assets, present and future, including uncalled capital. Trustees: C. W. H. Lowther, M.P., Albany, Piccadilly, W.; and J. G. B. Stone, 1, Sloane-terrace-mansions, S.W.

Bombay Electric Supply and Tramways Co., Limited.—A trust deed, dated Nov. 7, 1905, to secure £600,000 debenture stock, with power to issue further debenture stock not exceeding (together with the present issue) half of the company's issued capital, has been registered. Property charged: (1) a concession from the Corporation of Bombay, dated Aug. 7, 1905; (2) the Bombay electric license, 1905, and the Bombay electric traction license, 1905, and any licenses which may be vested in the company in substitution for or supplemental thereto; and (3) the company's undertaking and remaining assets, present and future. Trustees: The Right Hon. Lord Hillingdon, 67, Lombard-street, E.C.; and G. Herring, 1, Hamilton-place, London.

CONTRACTS FOR ELECTRICAL SUPPLIES.

London, W.—Messrs. Grice and Co., Addison Wharf, Warwick-road, Kensington, require a 10-ton electric derrick crane with 60ft. to 70ft. jib, continuous current.

Yarmouth.—Tenders are to be invited by the Port and Haven Commission for an electrically-driven crane. Including foundations, etc., the cost is estimated at £2,000.

Bermondsey.—Tenders for new plant, estimated to cost £5,390, will shortly be advertised for. An estimate is being prepared for condensing plant, for which tenders will be invited.

Omnibus Lighting.—A London motor omnibus company is open to receive proposals for the lighting of its vehicles by acetylene or electricity. Apply to Box 306, Willing's, 125, Strand, W.C.

Glasgow.—The Corporation invite tenders for the supply of 1,000-kw. motor-generators and high and low tension sub-station switchgear. Tenders by Dec. 4. See advertisement in last issue.

Brussels.—The Belgian Government Railways require tenders for lamps, accessories, etc., for railway carriage lighting. Specification No. 698 may be obtained from that authority. Tenders by Dec. 6.

Sao Luiz.—The Municipality require tenders for electric lighting of the town. Tenders by Dec. 16. Particulars may be obtained from the Municipal Secretary of Sao Luiz in the State of Maranhao, Brazil.

Launceston (Tasmania).—Tenders are invited for the supply of 500 or more electric meters and for maximum demand indicators. Tenders to Mr. C. W. Rocher, town clerk, Town Hall, Launceston, Tasmania, by 12 noon on Jan. 15.

Guadalajara (Spain).—Tenders are required for the electric lighting installations in various public buildings. The estimate is 11,343·00 pesetas. Particulars may be obtained from the Secretary of the Provincial Government at Guadalajara. Tenders by Dec. 8.

Castlerea.—The Rural District Council invite tenders for the construction of works for lighting the town of Ballaghaderreen: (1) builders' work; (2) hydraulic turbine plant; (3) electrical work. Specifications and particulars may be had from Mr. C. Mulvany, M.I.C.E., Engineer's Office, Athlone, on payment of £1 as a deposit, returnable after receipt of bona fide tender. Tenders by Dec. 23.

Poplar.—The Guardians invite tenders for the supply and erection of the following plant at the children's homes and schools now in course of erection at Hutton, Essex: (Section X) steam-engines, dynamos, pipework, etc.; (Y, part 1) main switchboard, wiring, motors, etc.; (Y, part 2) fire-alarms, telephones, and electric bells. Tenders to Mr. G. Herbert Lough, clerk, Guardians' Offices, 45, Upper North-street, Poplar, E., by 6 p.m. on Dec. 13.

Spain.—The *Gaceta de Madrid* of Oct. 10 contains details of a concession for the construction of an electric tramway as an extension to that of the east of Madrid. Tenders must be sent in by Dec. 13 to the Director of Public Works, Madrid, in whose office particulars may be seen. A deposit of 1,899·95 pesetas, or about £60, is required to qualify any tender. Local representation is necessary. The same journal of Oct. 12 contains a notice of a concession granted to the Sociedad Los Tranvias de Zaragoza for the construction of an electric motor tramway in that city. The *Gacetas* may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C.

Madrid.—The Directorate-General of Public Works, Madrid, require tenders for the concession of an electric tramway between Zumárraga and Azioitia, in the province of Guipúzcoa. An application for this concession has already been made by Don Dionisio Sorseta, who, at the same rates, will enjoy certain preferential rights over other tenderers. The competition will turn, in the first place, on a reduction of the tariffs proposed, and if two or more identical propositions are made, a further competition will take place verbally as to any reduction tenderers may be prepared to accept of the period (60 years) of the concession. A deposit of 6,897 pesetas (about £208) is required to qualify any tender.

Australian Commonwealth.—Tenders are invited by the Deputy Postmaster-General, Brisbane, for the supply and delivery at the Departmental Stores, Brisbane, of insulators, phosphor-bronze wire, copper sleeves, binders, and tapes. Tender forms, specifications, and conditions may be obtained from, and samples seen at, the Stores Branches, Postmaster-General's Department, Sydney, Melbourne, Adelaide, and Brisbane. Tenders by noon on Dec. 18.—Separate tenders are required by the Deputy Postmaster-General, Melbourne, for the supply and delivery at Melbourne of (1) 10 miles of 26-pair lead-covered paper-insulated telephone cable; (2) 1 mile of 156-pair lead-covered paper-insulated telephone cable (12½lb. conductors); (3) 5,000 barrel insulators delivery within three months of date of acceptance of tender. Tender forms, specifications, etc., and sample of insulator, may be seen at the General Post Offices, Melbourne, Sydney, Brisbane, Adelaide, Perth, and Hobart. Tenders must be endorsed "Tender for ——," as the case may be, and addressed to the Deputy Postmaster-General, Melbourne. They may be deposited in the tender-box at the General Post Office, Melbourne, or, if sent by post, must be prepaid and registered. Tenders by Dec. 17.

RESULTS OF TENDERS.

Melbourne.—The Corporation have accepted the tender of the Key Engineering Co. for 10,000 yards of 3in. fibre conduit

Salford.—The Electricity Committee have placed an order for 6,000 yards of fibre conduit with the Key Engineering Co.

Manchester.—The Electricity Committee have placed an order for 6,000 yards of fibre conduit with the Key Engineering Co.

Oldham.—The Electricity Department have placed an order for 3,000 yards of 2½in. fibre conduit with the Key Engineering Co.

Colonial Orders.—The D.P. Battery Co. have booked a 100-kw. battery for Australia and a small battery of 15 kw. for New Zealand.

Handsworth.—The Urban District Council have accepted the tender of Ellis and Ward, at £71. 19s. 10d., for altering the electric wiring and fittings at the Council house.

Digitized by Google

Northampton.—The tender of Nunn, Browne, and Co. to supply coal at the generating station for the ensuing 12 months has been recommended for acceptance.

Manchester.—The Electricity Committee have accepted the tender of the Key Engineering Co. for the supply and erection of a Harris-Anderson feed-water purifier for their Bloom-street works.

London County Council.—The amount of the contract for the ploughs for the 34 single-deck cars, which are being obtained for use on the southern tramways from the British Westinghouse Electric and Manufacturing Co., is £408.

London County Council.—The tender of Siemens Bros., of York-mansions, York-street, at £99. 16s. 6d., for providing a 30 h.p. electric motor in connection with the heating and ventilating apparatus at the Old Montague-street School, has been accepted.

Erith.—The Electricity Committee recommend that the contract with the Electric Construction Co. for the supply of motors to the Council for letting on hire be extended to March 31, 1906, upon the revised schedule of prices submitted by the company dated Nov. 10.

Bray (Ireland).—The Urban District Council have accepted the tender of Johnson and Phillips, Old Charlton, Kent, for 220 yards $^{7}/_{16}$ concentric paper-insulated and lead-covered cable, for a working pressure of 600 volts, at £13. 5s. per 220 yards; and that of the British Thomson-Houston Co., Rugby, for 10 10 ampere alternating-current induction voltmeters, 100 volts 60 periods, at £2. 2s. 9d. each.

London, S.W.—The London County Council are recommended to accept the following tenders for electric fittings, cables, etc. for the year 1906: Evered and Co., London; General Electric Co., London; Scerryn and Co., Birmingham; Dorman and Smith, London; J. Harrison, London; Armorduct Manufacturing Co., London; Baxter and Canter, London; Drake and Gorham, London; Verity's Limited, London; Craigpark Electric Cable Co., Glasgow.

Brighton.—The Town Council have accepted the tender of the British Westinghouse Electric and Manufacturing Co., at £1 462. 10s., for the installation of a motor-generator at the Southwick power station in connection with the supply of electricity to Aldrington; and that of the British Thomson-Houston Co., at £670, for the provision of a switchboard for controlling the low-tension circuits for Aldrington, the lighting, and the auxiliary motors at the Southwick power station.

Westminster.—The Finance Committee have received the following tenders for putting the electric light installation of St. Martin's-lane library in thorough repair:

T. Potter and Co., 44, South Molton-street*	£75	0	0
F. J. Coleby and Co., 7, Thayer-street, W.	73	12	0
Lund Bros and Co., 78, Queen Victoria-street, E.C.	88	0	0
L. Sunderland and Co., 39, Victoria-street, S.W.	104	0	0
Drake and Gorham, 66, Victoria street, S.W.	110	0	0
Foote and Milne, 66, Victoria-street, S.W.	119	10	0

* Recommended for acceptance.

Japan.—Messrs. Tokata and Co. have placed the following orders for electrical plant with the Westinghouse Co. of America: For the Furukawa Western Bureau—one 62½-kw., 570-volt, compound-wound, direct-current engine-type generator, direct connected to a Westinghouse 11 by 19 by 11 automatic compound engine. For the Senju Seijusho—two type 7 B direct-current generator panels; one type 7 B direct-current feeder panel; one type 7 B blank panel, all arranged to make a complete switchboard to control two 33-kw., 110-volt, shunt-wound, direct-current generators connected for three wire distribution. For the Kosaka Mine—one 15-h.p., 7 200 alts., three-phase, 220-volt, type C induction motor; one 3-h.p., 7,200 alts., three-phase, 220 volt, type C induction motor, which are to be direct connected to Denver Engineering Works electric mine hoists. For the Naval Briquette Works—one 10-h.p., 110-volt, shunt-wound, open-type S motor, with back gear, ratio of 5 to 1; one 5-h.p., 110-volt, shunt-wound, open-type S motor, with back gear, ratio of 5 to 1. For the Kimura Gold Mine—one type 13 three-phase generator panel, for one three-phase generator and one three phase feeder, 3,500 volts, 40 amperes; two 30-h.p., 200-volt, three-phase, 7 200 alts., type C induction motors; three 37½-kw., 7 200 alts., transformers: three 7½-kw., 7,200 alts., transformers.—*The Anglo Japanese Gazette.*

BUSINESS NOTES.

TRACTION.

Malaga (Spain).—The Malaga Tramways have obtained a concession for an electric tramway in Malaga.

Chili.—Don Fernando Petite has obtained sanction to construct and work an electric railway between Santiago and Banos de Colina.

Hythe.—Mr. Sellon, of the Folkestone, Hythe, and Sandgate Co., explained his tramway scheme to the Town Council last week, but was asked to submit same in writing.

Brighton.—The question of introducing ½d. fares into the tramway system has been before the committee, but further consideration has been deferred until the next meeting.

Cheshire.—We understand that the promoters of the Cheshire trams have decided not to proceed with the line between Cheadle, Handforth, Wilmslow, and Cheadle Hulme.

Dumbarton.—It has been agreed by the Western District Committee of the Dumbarton County Council to petition against the Dumbartonshire tramways order and the Dumbartonshire burgh extension order.

Belfast.—The municipal electric tramway service at Belfast was inaugurated at Belfast on Wednesday by a triumphal procession of six cars, on which were members of Parliament and representatives of all the local public bodies.

Cuba.—Application has been received by the Secretary of Public Works from Mr. G. F. Greenwood, the representative of the Cuban Electric Co., for permission to construct and work electric tramways in Regla and Guanabacoa.

Erith.—The Tramways Committee have invited the Bexley Urban District Council to discuss with them the question of inter-running and other matters of joint interest in connection with the tramway undertakings of the two authorities.

Scarborough.—The Marine-drive Sub-Committee have decided to submit a plan to the tramway company for the construction of tramways round the drive, which connects the North and South Bays, and is costing over £100,000 to construct.

Swinton.—The plans submitted by the tramway company for the construction of a tramway across the Midland bridge have been accepted by the Town Council, and an agreement will be entered into between the company and the Council as to details.

Northampton.—It will be recommended at the Council meeting on the 4th inst. that special school tramway tickets be in future printed and supplied by the Tramways Committee for the conveyance of scholars attending the Wellington-place School by trams at half fare.

Cleckheaton.—The District Council have agreed to confer with the Bradford Corporation in reference to the suggested linking up of the Spen Valley and Bradford tramway systems at Oakenshaw, on the suggestion of the Yorkshire (Woollen District) Electric Tramway Co.

York.—The Streets and Buildings Committee have appointed a sub-committee to deal with the resolution of the City Council remitting the question of the acquisition of the street tramways to them, with instructions to effect the purchase of the tramways if possible.

Liverpool.—The widow and daughter of Mr. James Sykes, a cashier, of Liverpool, were at Liverpool on Tuesday awarded £1,100 damages against the Lancashire and Yorkshire Railway Co. in respect of the loss of Mrs. Sykes's husband, who was killed in the Hall-road electric train accident.

London, Brighton, and South Coast Railway.—A correspondent writes to the *Times* that the London, Brighton, and South Coast Railway Co. are preparing to go ahead with the electrification of their South London line on the single-phase system. It is believed the contract will be undertaken by the Allgemeine Elektricitäts-Gesellschaft.

Dunfermline.—The promoters of the Dunfermline and district tramway scheme have agreed that the system to be introduced in the town should be the single-double line; that means the laying down of the double rails, but only traffic on one side of the street at a time. Application is to be made to the Secretary for Scotland for power for the construction of the tramways in the town and district.

Lincoln.—A public service of cars over the new electric tramways was started on the 23rd ult., the first car being used by the mayor and Corporation for a trip along the entire system. The line, which is a little under two miles long, is operated by the "G. B." surface-contact system, Lincoln being the first town to adopt it for a public service. The tramways have cost £20,000, and there are eight cars, which have cost about £600 each.

Heywood.—The section of the tramways from Heap Bridge to the Reform Club was officially inspected last week. The inspector (Colonel Druitt) went over the whole of the track and passed it, fixing the speed at which the cars should travel at 14 miles an hour, with the exception of Bridge-street and Market-street, Heywood, the speed in those streets not to exceed 10 miles an hour. The route was opened for traffic on the same day.

Torquay.—The Town Council Electric Lighting Committee have under consideration an offer from the National Electrical Construction Co., of Westminster, who are constructing the tramways for the Dolter Co., to buy or lease the electrical station from the Corporation. The Local Government Board has, after nearly 12 months, sanctioned the enlargement of the electrical station, at a cost of about £10,000, in order to provide current for trams.

West Ham.—The Electric Light and Tramways Committee recommend the Council not to identify themselves at the present time with the metropolitan boroughs who are contemplating the promotion of Bills in Parliament during the ensuing session for obtaining powers for supplying electricity in bulk. A proposal was before the Council at their meeting on Tuesday for the adoption at the various tramway termini of a better method for the regulation of passenger traffic.

Hampstead.—The application of the London Motor Omnibus Co. for the Borough Council to withhold their support to the Bill to be promoted by the London County Council for the provision of an electric tramway from Cricklewood to the Marble Arch, on the grounds that the problem of London traffic could be better solved by the provision of motor omnibuses than by the provision of electric tramways, has been referred to the General Purposes Committee for consideration.

Wembley.—The District Council having objected to the scheme of the Middlesex County Council for an extension of the tramway system to Swan, had before them an intimation from the same authority that they were going to apply for powers for a light railway commencing at a point one chain east of the Wembley and Harrow boundary, extending east to link up with the line in course of construction. The District Council have passed a resolution to the effect that this proposal is sufficient compliance with their wishes to enable them to reconsider the question.

Dundee.—A report has been issued by the tramway manager on the question of interchanging traffic with the new district tramway from Dundee to Monifieth, which will be opened shortly. The latter belongs

Digitized by Google

to a limited liability company, and when the company obtained the order, power was taken for the changing of crews at Dundee. Mr. Fisher, the Dundee manager, suggested, however, that the drivers should run right through either way, and that the conductors only should change at the boundary, pointing out that this would obviate the conductors collecting fares in territory over which their employers were not owners.

New South Wales.—The report of the Railway Commissioners on the working of railways and tramways in the Colony for the quarter ended Sept. 30 shows that the tramway earnings were increased by £2,247, while the expenditure was decreased by £2,879, which is an improvement of £5,126 over the corresponding quarter of last year; 16,892 additional passengers were carried, but tram mileage shows a decrease of 86,082 miles. The revenue during the period under notice amounted to £194,598, expenditure £160,033. The total number of tram miles run were 4,035 595, the earnings of which were 11½d. per mile, as against an expenditure of 9½d. Expenditure absorbed 82·24 per cenc. of the earnings.

Musselburgh.—With regard to the proposed application for powers to construct tramways which we announced last week, we understand that the Town Council consider some of the routes dangerous, and have decided to insist that where the new line ran through the burgh there should be at least the regulation minimum of 9ft. 6in. space left on each side of the road between outer rail and kerb, and that the road be widened where necessary to effect this; also that a minimum of 5ft. of footway be left on the north side of the road, and that Ravenshaugh Bridge be widened and made secure for traffic. They have also agreed that wayleave be charged, but the sum and other matters have been referred to the committee.

Longton.—Major Druitt inspected the new section of the Potteries Electric Tramway on behalf of the Board of Trade on Friday last. The new line traverses a long incline and terminates near Heathcote-street close to the cutting which opens into Adderley Green district. The termini of the new tramway will be Longton Market-square and Heathcote-street, and the fare will be 1d. for the single journey. The contract for the permanent road has been carried out by Mr. Law, of Kidderminster, and the installation of the overhead equipment was in the hands of the Potteries Electric Traction Co. We understand that subject to the inspector's satisfaction the new section will be opened to the public to-morrow ((Saturday).

Cardiff.—In answer to the complaints made against the frequent repair of the track between Leckwith-road and Theobald-gardens, the engineer (Mr. Harpur) reported to the Tramways Committee that the unsatisfactory state of the track between these points was due to the Corporation having utilised, with the object of economy, the concrete foundation of the old tramway, for which they had paid a big price. The Chairman said the only remedy was relaying and a double track, while Mr. Harpur added that rewidening was proceeding now at the spot referred to. The committee have declined to receive a deputation of tramway employés and representatives from the Tramway and Vehicle Workers' Association to discuss the charges made by the tramways manager against some of the employés.

Wandsworth.—The Borough Council have consented to the introduction of a Bill by the London County Council to obtain powers for the construction of a tramway from Clapham to Lavender-hill, upon the following conditions: the London County Council to pave with wood the whole width of the carriageway of Long-road and North-side, Clapham Common, from South-side to Cedars-road, making the width 33ft., and setting back the kerb for that purpose, and adding a strip of the common to the public way if necessary; the London County Council to construct a surface-water sewer along Long-road; the Borough Council to pay one-third of the cost of the works referred to; the London County Council to reconstruct as a double line and electrify the existing tramways from the junction of Cedars road and Lavender-hill to East-hill, Wandsworth, as soon as possible.

Newcastle.—A meeting of the representatives of the Tramways Committee of the Corporation and the representatives of the tramway employés took place on Tuesday for the purpose of endeavouring to settle the dispute arising out of the late strike. The questions brought forward by Mr. Tate (on behalf of the tramway employés) for consideration were extra remuneration for men working on Sundays, and also extra duty on other days; excessive hours of work; and the reinstatement of a Gosforth conductor, who was alleged to have been wrongfully dismissed. A long discussion took place, but no definite conclusion was come to. It was, however, arranged that a special meeting of the sub-committee, along with Mr. Tate, be held to-day to consider the case affecting the car conductor, and that the next conference between the whole of the representatives take place on Tuesday next.

Hammersmith. — In response to the application of the London County Council for payment of a sum of £1,973. 11s. 11d. by way of a contribution towards the costs and expenses incurred by the Council in carrying out reconstruction and widening of roads in the borough, the Borough Council have informed the London County Council that before any payment is made the whole of the improvement should be completed. The Council consider that the number of men employed in repairing the tramways permanent track in the borough is not sufficient, and have informed the London United Tramways Co. that unless the work of repair is pushed forward more rapidly to the satisfaction of the Council, the Council will put in force the provisions of Section 28 of the Tramways Act, 1870, enabling the Council to do the works necessary for the repair and maintenance of the roads and charge the company with the cost.

Dewsbury-Batley.—The Bradford-road section between Dewsbury and Batley was officially inspected last week by Colonel Druitt on behalf of the Board of Trade. As far as construction was concerned, Colonel Druitt found everything to his satisfaction. In regard to a portion of the Dewsbury section near the railway arches, he had to draw attention to the manner in which the ordinary paving had been joined up with that nearest the tramrails. The Dewsbury Corporation aver that it is the duty of the British Electric Traction Co. to put this right, while the company throw the responsibility upon the Corporation. Sanction was given for the running of cars for the public at noon, and it is understood that between Dewsbury and Branch-road, Batley, a speed of 14 miles per hour will be allowed, and between Branch-road and Birkenshaw 16 miles per hour. This is more than double the speed of the old cars, so that travellers will be able to appreciate the difference.

New London Tube.—A new railway from the Marble Arch to Cricklewood, authorised in 1899 but delayed on account of the South African War, is now to be carried out, and, in addition, powers will be sought from Parliament in the coming session to extend the line to Victoria. The promoters of the scheme propose to construct subways for the convenience of passengers wishing to change to other lines, communicating with the District Railway, Victoria, the Great Northern, Piccadilly, and Brompton Railway at Hyde Park-corner, and the Central London at Marble Arch. It is probable also that the Baker-street and Waterloo Railway's extension to Paddington will be connected with the proposed North-West London line. It is also intended to construct some short branch lines to facilitate intercommunication with the tramways. The actual lines will not, of course, be joined, but subways will be built leading to the existing tramway route. It is understood that the estimates aggregate over £2 500,000. The proposed extension to Victoria follows the lines of one of the recommendations of the Royal Commission on London Traffic.

Abram.—The following are some of the conditions upon which the Council would consent to the sale to the Wigan Corporation of that portion of the South Lancashire tramway undertaking which is in their district: That any setts excavated in the construction of the tramway shall not be broken up into road ballast, but shall be applied only as setts in or towards the reinstatement of the road; that the Corporation when constructing the tramway shall at their own expense provide proper means of lighting the entire route of the tramway (constructed) on the trolley wire standards at points in the road, to be approved by the Council, and shall continue, so long as the tramway remains in existence, to light the road at their own expense with electricity; that so long as the tramway continues in use there shall be issued to the Council, free of charge, passes over the Corporation tramway system for the clerk, surveyor, medical officer of health, nuisance inspector, and collector for the time being, and also for three members of the Council, whose names shall from time to time be furnished by the Council to the Corporation; that the Corporation shall widen Dover Bridge.

Southampton.—The report of the tramways manager upon the working of the undertaking for the six months ended Sept. 30 was presented to the Town Council at the meeting last week. From it we gather that the working expenses, excluding any work on the track, showed a saving on the estimate of practically £240, and a saving of about £150 on the power bill. Allowing for the extra mileage run, the units per car mile have dropped from 1·185 to 1·161. In spite of the large amount of work done, the expenditure for track repairs only exceed the estimate by £54. The traffic receipts show a small decrease when compared with the corresponding period of last year, the amount taken being £26,939, as against £27,464 being a decrease of £51b. The interference to traffic caused by the various reconstruction works accounts for some of this decrease, while the absence during the six months under review of any popular attraction in the town was very noteworthy, and had been a severe loss to the department. This decrease of traffic receipts was not local, for very nearly all the undertakings in the country which have not increased their route mileage and car mileage show a similar decrease. During the six months the Corporation have reconstructed 1,824 yards of single track at a cost of £4,663, and have also put a further 500 yards of track into a state of thorough repair. In moving the adoption of the report, the chairman of the Tramway Committee consented to refer back the financial portion for preparation by the borough treasurer.

Durban.—The annual report of the manager of the tramways states that with the exception of an interruption of the supply owing to the failure of water, as the result of the storm in June last, no serious hitch occurred to the supply of current to the tramways, and they are now being charged for all current at the rate of 1½d. per unit, which, of course, only includes the actual operating cost, and does not include any capital charges. As there appears to be considerable misapprehension in certain quarters as to the reason of this, and an idea that the capital accounts of the tramway and electrical departments have not been regularly kept, the manager explains that the reason the latter do not make a charge for interest, etc., is that the machinery in the power station for generating current for tramways was bought and paid for out of the tramway loan, and this was the only course which could have been taken, as such machinery could not have been paid for out of a loan which was raised for electric lighting purposes. When the electrical department was completely separated from the tramway department, it became necessary, or convenient, that the cost of tramways machinery should be transferred to the other account; but until recently the capital account of the electrical department was overdrawn, and had not the funds to take over this expenditure. Funds now, however, are available, and the transaction of transferring about £40,000 to £50 000 can be made, and the price charged to the tramway department per unit will have to be increased to cover the interest and depreciation on the amount transferred. The cost to the electrical department of generating 1,548,000 units was £7,110, and the repairs to underground mains necessitated an expenditure of £334.

The Underground Railways.—Some important reductions have been announced by the District Railway Co., which come into operation to day. Over the Inner Circle portion of their system the single-journey fares will in no case be in excess of 4d. first-class and 2d. third-

Digitized by Google

class. The fares from Earl's Court, High-street (Kensington), Gloucester-road, South Kensington, Victoria, etc., to all City stations to Aldgate East will now be 4d. first and 2d. third, instead of 6d. first and 3d. third, as formerly. The Metropolitan Railway are also reducing the fares by their route from South Kensington to the City *via* King's Cross, the journey being accomplished on and after to-day for 2d. third-class and 3d. first-class. Already the omnibus companies have extended some of their stages westwards to meet the competition by the electrified railways and motor-driven 'buses. The increased comfort with which a journey can now be made on the Underground Railway has fully justified the electrification from the public point of view. The change is also being justified from the standpoint of the companies. In conversation with a representative of the *Evening Standard and St. James's Gazette*, the deputy-chairman of the District Co. said that over 200 000 more passengers were being carried than was the case at this time last year. The increase has temporarily added to the army of "strap-hangers," but at present the company is helpless in the matter. The Board of Trade, Mr. Perks pointed out, would not allow a more frequent service of trains to be run until the automatic signalling arrangements were at work. He believed, however, that the last of the steam trains—those of the London and North-Western—would be adapted to the new conditions by Friday, and he hoped the automatic signals would be installed before the close of 1905.

Middlesbrough.—Details of an important private scheme in the shape of a light railway for more rapid communication between Middlesbrough and Hartlepool have been issued, which include the erection of a transporter bridge across the Tees. A junction will be effected with the Middlesbrough tram system at the Ferry-road terminus, and the lines will be laid along Ferry-road to within about four yards of the clock tower, thence across the transporter bridge (measuring, with its approaches, about 360 yards), terminating at the southern end of the road leading from the existing ferry entrance gates to the Port Clarence railway station. From this point it is proposed that a line will be laid along the Haverton Hill-road to Haverton Hill, and thus along Clarence-street to Hope-street. From this point the line will cross the fields to Cowpen Bewley. Crossing by an overhead bridge the railway lines at the Cowpen gates, the route taken will be in the direction of Greatham, entering the village at the point where the footpath from Cowpen enters. Passing along by the graveyard to the main roads, the light railway is to be laid along the west side of the road to a point opposite the Travellers' Rest public-house, thence along the road to its junction with Stockton-road, and afterwards to Foggy Furze, terminating by a junction with the electric tram system at their termination. The full length of the route is over 7½ miles, and the depôt and power station is to be situated at Cowpen Bewley. The lines will be constructed with a gauge of 3ft. 6in., and electric power independent of the light railway or tramcar system. Representatives of the Council have given their opinion that the Corporation should construct the transporter bridge, and at a reasonable figure give the company running powers over the bridge. It is likely, however, that the scheme will meet with opposition from the N.E.R. and the Middlesbrough Corporation.

London County Council.—At the usual weekly meeting on Tuesday last Mr. Allen Baker, M.P., chairman of the Highways Committee, said that the projected tramway from Holborn to Hampstead, through King's Cross, was in the third section of the northern tramways, and would be proceeded with probably within a year or two of the completion of the first 22½ miles. It was hoped that the Dulwich line would be proceeded with as soon as the generating station at Greenwich was ready. The special report on the electrification of the northern tramways would be presented at the meeting next week. The Highways Committee recommend that the estimate of £1,200 in respect of the provision of 500 additional ticket-punches for use on the Council's trams be approved, and that the punches be made by the staff of the tramways department. The Highways Committee, as to through tramways from Aldwych to the Angel at Islington, resolved: "That the supplemental estimate of expenditure on capital account of £7,000 be approved, in addition to the amount of £33,000 included in the estimate approved on Aug. 1, for the purchase of electric cars for use on the through tramways route between the Strand and the Angel, Islington. That expenditure on capital account not exceeding £27,761 be sanctioned in connection with the supply of 34 single-deck steel electric cars required for use on, or in connection with, the through tramways route between the Strand and the Angel, Islington. That, subject to the result of the usual inquiries proving satisfactory, the tender, amounting to £14,280 of the Brush Electrical Engineering Co. for the supply and delivery of 34 single-deck steel tramcar bodies be accepted. That, subject to the result of the usual inquiries proving satisfactory, the offer of the British Westinghouse Electric and Manufacturing Co. to undertake the supply and delivery of 34 tramcar trucks and electrical equipments, and the assembly of the cars for the sum of £13,184 be accepted." The Council confirmed the committee's resolutions without discussion.

Croydon.—The obstacles which have stood in the way of an amicable settlement of the tramways question now seems to be disappearing by the submission of the differences between the Corporation and the British Electric Traction Co. to arbitration, and by the report which was presented by the Tramways Committee at the last meeting of the Council. The committee are advised and recommend the Council to resolve and determine that notice be given to the company terminating the leases of Jan. 23, 1900, and March 2, 1903; that the corporate seal be affixed to the lease to the British Electric Traction Co. of tramway No. 20, authorised by the Croydon and District Electric Tramways Act, 1902, in accordance with the said Act and the award of the arbitrator; and that six months' notice to determine the proposed lease of tramway No. 20 aforesaid, such notice to expire at the same time as any notice given by the Corporation to determine the lease of Jan. 23, 1900, be given to the company in accordance with Section 35, Sub-Section 14, of the Croydon and District Electric Tramways Act, 1902. The committee recommend that the extension of the tramway from Thornton Heath terminus to the Gloucester, authorised by the Croydon Corporation Act, 1905, be constructed as a double line throughout. The borough road surveyor and the borough electrical engineer reported with reference to the condition of the tramway track and electrical equipment, giving details of repairs and renewals required, at an estimated cost of £2,106. 16s. 11d., that the track paving is in good condition throughout. The lessees have not yet, however, attended to the corrugated rails mentioned in the former reports. The committee have been in communication with the local manager as to the wearing down in places of the rail lip or check to below the running tread, on an average from ¼in. to ⅜in., and also as to several necessary renewals. The overhead equipment appears to be in good condition. The feeder section and Quin pillars have been examined and found satisfactory, and the Quin switches were tested and found in working order. The state of these boxes is much better than it was 12 months ago. A general examination of the cars was made and a detailed examination of the equipment of certain of the cars taken haphazard. The motor bearings, gearing, lifeguards were found in good order. Certain controllers were selected and examined, and these were also found in good condition. Electrical tests were carried out on some of the motors, and these were also found satisfactory. Trial trips were made on two bogie cars and the brakes tested, and found to be in order. The whole of the above part of the equipment, etc., of the tramways are maintained in a satisfactory condition, with the exception of certain bonds which show a leakage of current. The report was adopted by the Council. An order has been received from the Board of Trade sanctioning the borrowing of the following sums for the construction and equipment of tramway No. 20, authorised by the Croydon and District Electric Tramways Act, 1902: £4 302 in respect of the permanent way, to be repaid in 30 years from date of borrowing; and £1,798 in respect of the electrical equipment, to be repaid in 20 years from date of borrowing.

LIGHTING AND GENERAL.

Falkirk.—A new agreement with consumers has been prepared in consequence of the change of the price of current.

Carnarvon.—An inquiry has been held into an application for powers to borrow £1,000 for electric lighting purposes.

Leek.—Combined shops and houses having at least six 8 c.p. lamps fixed in the house are to be allowed an alternative flat rate.

Quillota (Chili).—The General Industrial Electricity Committee have obtained sanction to supply the town with electricity.

Salford.—Power consumers will from Jan. 1 be charged for current for lighting purposes at the power rate up to 15 per cent. of their power consumption.

Brussels.—During Sunday's storm the new municipal electricity works, which were approaching completion, sustained damage to the extent of £12,000.

Swansea.—The extensions for electricity supply to Morriston and Sketty are so far completed that the houses already wired may be supplied by Christmas.

Llanelly.—The electric lighting agreement with Mr. Howell was further discussed at the last Urban District Council meeting, but no decision was arrived at.

Holyhead.—An inquiry has been held into an application for sanction to borrow £3 000 for electricity extensions, £1,720 of which amount is for new work.

Valparaiso (Chili).—The Valparaiso Electric Lighting and Tramways Co. have obtained permission to make the necessary installations for lighting the streets in Valparaiso for the next 10 years.

Leeds.—The Yorkshire Electric Power Co. are about to lay down an electric installation at Horsforth, and throughout the West Riding are developing the system of electricity for manufacturing and public purposes.

Northampton.—Notices from the electric light and power company of their intention to extend electric light mains in Henry-street, Shakespeare-road, and Grey Friars-street have been received by the Town Council.

Maryport.—The Urban District Council have appointed a committee to consider the applications to Parliament for the supply of electric light and power by the British Electrical Engineering Co. and the Cumbrian Electric Power and Gas Co.

Mexico.—An application has been made by Señor Félix Araiza for an appropriation of 2 000 litres per second for the production of motive power from the waters of the River Bolaños, situated between the State of Jalisco and the Territory of Tepic.

Dunstable.—The Town Council have decided to appoint a committee in regard to the application of the Provincial Electric Light Corporation for a provisional order to empower them to supply electric current for light and power within the borough.

Rochdale.—The Corporation's high-tension supply will shortly be in working order. The cables for this would pass near the workhouse, and the Guardians have asked for a quotation with the view of considering the question of taking a supply of electricity from the Corporation.

Sheffield.—The electric supply department have decided upon a reduction in the price of electrical energy for heating and cooking to 1d. per unit from the commencement of the New Year. This is about the cost per hour of the four-light luminous electric radiator they supply.

Dover.—Messrs. Pearsons, the contractors, are being pressed by the Admiralty to complete the harbour works by next October. They

Digitized by Google

consequently require additional supplies of electric power from the Corporation works. A committee has been appointed to deal with the matter.

Worcester.—The City Council have approved the expenditure of £225 in carrying out work in the electricity transformer chambers in the city to meet the demands of the factory inspector. The appointment of Mr. B. Smith as temporary junior assistant at 10s. per week has been approved.

Burslem.—The electric light installation at Chell workhouse is now in full working order. The whole of the work has been designed by and carried out under the superintendence of Mr. Ashton Bremner, the borough electrical engineer of Burslem, who has acted as consulting engineer to the Guardians.

West Ham.—Last Tuesday the Council received a report by the town clerk on electricity supply in London, in which he said that if the London County Council proceed with their suggested Bill it might be advantageous for West Ham to support the same in preference to joining the other borough councils.

Stock Exchange.—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to the Bombay Electric Supply and Tramways Co.'s 60,000 6 per cent. cumulative preference shares of £10 each, Nos. 1 to 60,000, and £600,000 4½ per cent. debenture stock.

Stirling.—Mr. Hanson's last report shows that during the four weeks ending Oct. 28, 28,368 units of electricity have been generated at the power station, as compared with 23,914 for the corresponding period of last year. The total connections in equivalent 8-c.p. lamps up to date was 18,291, as against 16 273 at the same period last year.

Brighton.—An inquiry will be held by Mr. H. Ross Hooper, C.E., on Dec. 12 into the application of the Town Council for power to borrow £38,500 for purposes of electric lighting, and £5 909 for the purpose of acquiring the site of the Star Foundry in Bread-street and the erection thereon of buildings in connection with the electric light undertaking.

A New Telegraph Line.—The *Globe* St. Petersburg correspondent says that direct telegraphic communication has been established between Ashabad and Meshed in North-East Persia. Meshed is of great importance, not only by reason of its trade, but also as being the Mecca of Persia. It is the capital of Khorassan, and is 201 miles north-west of Herat.

Norton (Malton).—The Northern Counties Electricity Supply Co. have obtained permission to lay a cable from the railway through the Council's premises to Commercial-street, subject to the company entering into a written agreement to remove same on being notified and paying 5s., such notice, however, not to be given until the expiration of 10 years from the date of the agreement.

New Zealand.—The Wellington city engineer is having plans prepared for the new rubbish destructor to replace the now obsolete one at Clyde Quay. The ratepayers lately sanctioned a loan of £20,000 for this purpose, and Mr. Norton is of opinion that very considerable energy can be generated by the heat, even an electric plant on a small scale.—*N. Z. Mining, Engineering, and Building Journal.*

Mansfield.—The electrical engineer in his last report gives the following figures: units passed out of works, month ended Oct. 31 1905, 24,972, an increase of 8,873 units on the previous year; traction units generated during the month, 17,334; number of applications to date, 247; new connections during the month with an equivalent of 449 8-c.p. lamps, 15. Feeder mains are about to be laid to Mansfield Woodhouse.

Westminster.—The Council have received a letter from the Westminster Electric Supply Corporation stating that they have decided to reduce the charge for current for purposes other than lighting—*i.e.*, for power, heating, and cooking—to 1d. per unit net as from Jan. 1 next. The charge for electric current for power purposes recently concluded with this and the other electric supply companies at present supplying premises belonging to the Council is 2d. per unit.

Johannesburg.—We are informed that Messrs. Newtons Limited, of Taunton, are this week shipping to the Jubilee Gold Mining Co., Johannesburg, a large generator and two motors of their well-known "Mawdsley" type, together with main switchboard and two controlling panels, and that this is the third repeat order they have received from that firm during the last few years, proving conclusively the suitability of their machines for mining purposes generally in South Africa.

Erith.—The Urban District Council having had some trouble with their rotary converters, and as they are required to take the tramway load during mealtimes, it has been agreed that the resident electrical engineer obtain estimates from not less than four electrical firms, alternatively, for one 200-kw. and for one 250 kw. rotary converter complete, with transformers and switchgear. Extension of mains, transformers, etc., are to be provided in connection with a supply to the works of Messrs. Vickers, Sons and Maxim.

Croydon.—The committee have decided to supply electricity on special terms to basements having no natural light for the purposes of power, heating, and lighting at a flat rate of 2½d. per unit. The borough electrical engineer in his last report says, with regard to work for unemployed that he is at the present time unable to find extra work for men inside the electricity works. In the outside department a considerable number of men are employed for cable-laying when the weather permits, and this work will extend more or less through the winter.

Henfield.—The National Telephone Co. have opened a local exchange at Henfield. The National Co. now embraces several areas not touched by the competing Brighton municipal system, Henfield, Keymer, Ditchling, and Rottingdean being exclusively served by the company. It is reported that in the Brighton area the National system has been making extraordinarily rapid progress. On Sept. 7 last the company had 3,681 stations in the Brighton area, compared with 1,973 Corporation stations. On Nov. 23 the Corporation had increased to 3,009 stations and the National to 3 902.

Heylake and West Kirby.—The last report of the Electric Supply Committee shows that during October 40,236 units were generated and 30,162 consumed, the total consumers numbered 692, and the estimated revenue was £567, while the estimated expenditure was £462, the net profit for the month being £105. The net loss since March was £526, as compared with a corresponding loss last year of £745. This profit of £105 compares with a net profit in October last year of £20, a gain of £85. The West Kirby station is progressing favourably, and the arc lamps will probably be completed early in December.

Barnstaple.—At their last meeting the Town Council discussed a recommendation of the Electric Light Committee that from Jan. 1 all private consumers other than the Town Council be allowed a discount on the year's account of 5 per cent. on amounts between £2 and £5; above £5 and not exceeding £10, 7½ per cent. discount; above £10 and up to £50, 10 per cent. discount; and above £50 12½ per cent. discount. On a vote the principle of allowing discounts was adopted, and the matter then deferred to the end of the year. The Ilfracombe Electric Lighting and Power Co.'s application to be supplied with current for all purposes at power rate for a branch they intend opening in Barnstaple was not entertained.

Hampstead.—The total income of the electric lighting undertaking of £23 189 includes £1 895 received from consumers transferred from the North-West London Electric Supply Co., whose business was recently purchased by the Council. The Council have decided to continue the tenancy of the land upon which the North-West London Electric Supply workshop and buildings purchased from the company stand. The Midland Railway Co. have increased the rent from £76 to £200 per annum. Certain parts of the premises, however, are let by the Council for £225 per annum, and the Council have still offices with rooms over and a workshop which can be used for the purposes of the electric lighting undertaking.

London Gazette.—The partnership between G. F. Frizell and E. C. Louis, carrying on business as electricians at 79, Denmark hill, Camberwell, has been dissolved by mutual consent. A receiving order has been made out on creditors' petition in the estate of W. G. Leather, electrical engineer, trading as the Windus Electric Co. at 25, Howard-street, Sheffield. The last day for receiving proofs in the estate of Messrs. Holmes and McCallum, electrical engineers, Crown Works, Darwen, is Dec. 13. Gerald Algar, electrical engineer, and trading as G. Leslie at 5, Denning-road, Hampstead, London, has made application for debtor's discharge. Luke Jesson Sharp, 191, Corporation-street, Birmingham, has been released from trusteeship in the estate of James Marsden, electric fittings manufacturer, Woodcock-street, Birmingham.

York.—The last report of the Electricity Committee contains the following return for the month of October last: Units generated—public lamps, 17,765; power and private lighting, 80,991; used at works, offices, and battery, 13,455; used by private arc lamps, 2 349; unaccounted for, 7,874—total, 122,344. Estimated income—public lighting, £99; power and private lighting, £916; motor and radiator rents, etc., £39—total, £1,054. Total income per unit sold, 2·56d.; horse-power of motors connected during month, 7; total horse-power of motors connected to date, 742; 8-c.p. lamps connected during month, 495; total 8-c.p. lamps connected to date, 48,817; equivalent 8-c.p. connected—total, 67,367. The total cost was £502, and cost per unit 1·22d. The total cost for the corresponding month last year was £473, and cost per unit 1·28d.

Barnsley.—An inquiry has been held into an application of the Town Council for sanction to borrow £3,000 for purposes of electric lighting. Mr. E. A. Barker, borough electrical engineer, said the works were opened on Feb. 17, 1900, and at the end of the financial year (March, 1901) the receipts were £2.250, and the expenditure £2,242, leaving a credit balance of £8. In the following year (1902) there was a debit balance of £97. receipts being £2 491, and expenditure £2,589. The income in 1903 was £3 338, and the expenditure £3 244, showing a profit of £93. In 1904 the income was £8 348, and the expenditure £7 376, the credit balance being £972. Receipts in 1905 totalled £9,675, and expenditure £7,832, the profit being £1,842. The loan was for the making of services, meters, and mains, the approximate cost of each being: services, £1,100; meters, £850; and mains, £1,050.

Brighton Telephones.—Competition being the theme of a discussion at the last Council meeting, Councillor Lintott said that subsequent to the Local Government Board inquiry about six months ago they received about 80 notices to discontinue. Of these, probably about 50 per cent. were the outcome of the influence of the company's canvassers. The committee, however, ascertained from the subscribers that these were provisional notices, with a request to be waited on a few days before expiry. In fact, quite 60 per cent. had withdrawn their notices, and although the Corporation had received 80 notices to discontinue they had added 195 new lines or instruments. To-day there were 2.009 lines or instruments connected, a number, he believed which had never yet been reached by the system; so no one could truthfully say the department was in any way going back. Considering the present state of uncertainty with regard to municipal telephones all over the country, the committee felt it was their duty to give their subscribers public assurance that it would be their endeavour to see that none were permitted to suffer through their loyalty to the Corporation system.

Leith.—The National Telephone Co. have just opened a new telephone exchange on the "central battery" system. A compact power plant, consisting of a duplicate set of motor-generators and a storage battery of 11 large cells, now takes the place of the magneto-generators and small primary batteries formerly attached to the subscribers'

Digitized by Google

instruments. The storage battery, periodically charged by the motor-generator, supplies current for operating the system, while a separate motor-generator is utilised for ringing and testing purposes. The switchboard is at present equipped for 1,000 direct exchange lines, and has an ultimate capacity of 3,000; there are nearly 100 junction lines, and the service is under the control of 12 operators. It is interesting to note that at the present time there are 650 direct exchange lines and 130 private lines passing through the test-room. Over 1,000 instruments are working, and it is computed that about 30 000 messages pass through the exchange each day. For some time the National Telephone Co. has been occupied in converting its huge London system to the central battery method of working, and it has also constructed new exchanges of the same character in several of its provincial centres. The conversion of the Edinburgh system, where the switchboard is already equipped with lamp signals, but not with the full automatic working, will shortly follow, and it is the policy of the company to eventually convert all its large systems to the central battery working.

Preston Dust Destructor.—At the Sheffield congress of the Association of Cleansing Superintendents, Mr. Thomas Lloyd, cleansing superintendent to the Corporation of Preston, read a paper on cremation and utilisation of the town's refuse. The latest installation consists of four four-grate Meldrum patent Simplex regenerative destructor furnaces, each unit having a total grate area of 100 square feet, the plant being so arranged that any pair of units can work together. The economisers are of Messrs. E. Green and Sons' make, and contain 288 pipes, arranged in three groups, eight pipes wide. After describing the installation in detail, Mr. Lloyd said that steam was supplied by the destructor for the horizontal cross-compound engines, each with a maximum of 470 h.p., which supply the means for generating electricity, and supplying the tramway department with sufficient steam to generate 20 000 units per week on an average. The total number of units generated from Dec. 29, 1904, to June 21, 1905, was 487,644, sufficient to run the tramways over 10 miles of streets with a length of track of 16 miles for that period. During this time the cars have covered a distance of 354 046 miles. The destructor is shortly to supply the power to generate the electricity for lighting the car-shed and workshops at the car station; also for the destructor buildings, stables, storeyard, and workshops connected therewith, besides supplying steam for a large Defries disinfector, thus creating a considerable saving to the ratepayers.

Hammersmith.—The premises of 28 additional consumers, representing a maximum of 972 8-c.p. lamps, have been connected to the mains, and seven consumers have been disconnected. The present number of consumers taking current from the mains is 1,756. The Council will not join the Notting Hill Electric Lighting Co. in their Bill, which is being prepared under the instructions of the joint Boards of the Kensington and Knightsbridge Electric Lighting Co. and the Notting Hill Electric Lighting Co. The main object of the proposed Bill would be an association of the existing companies and local authorities now holding statutory powers under the Electric Lighting Acts in West London, including Hampstead, St. Pancras, Hammersmith, and Fulham and the Bill would authorise the associated companies and local authorities to interchange bulk supply, and to supply energy within the area of each of the associated companies and local authorities, but only with the assent of the company or local authority in possession of the area in question. A letter has been received from the Incorporated Municipal Electrical Association suggesting that an endeavour should be made to induce the Local Government Board to allow the expenses of delegates attending the conferences of the association, in the same way as are expenses of delegates to meetings of the Urban District Councils' Association. We understand that no action will be taken in the matter. A second crane is to be purchased for the works at a cost of £49.

Birmingham.—The Electric Supply Committee, in their report to the City Council, recommend the adoption of a reduced scale of charges, as follows: Lighting supply—for first 300 units per quarter, proposed new charges, 5d. per unit (present charges, 6d.); for any further quantity in same quarter, 3½d. (4d.). Day lighting supply—for first 300 units per quarter, 3d. (3d.); for any further quantity in same quarter, 2d. (2d.). Power supply—for first 300 units per quarter, 2d. (3d.); for any further quantity in same quarter up to 3,000 units, 1½d (2d.); where 3 000 units or over per quarter are used, after first 300 units, 1¼d. (1½d.). These charges are subject to 5 per cent. discount for prompt payment. On last year's figures, which showed a net profit of £10,789, these reduced charges would have decreased the receipts by about £9,750. The Council state that, having regard to the large payments for interest and sinking fund that will have to be met on increased capital expenditure now being incurred by the department, which expenditure cannot be expected to be remunerative for the next two or three years, there is no doubt that the revenue during this period will not be sufficient to fully meet the increased charges. It will be necessary, therefore, to draw upon the reserve fund, which has been accumulated to meet such an eventuality. This fund now stands at £49,393. 19s. 2d., and will be more than sufficient to meet any deficiency that is likely to arise on this account. The reduced charges, if approved, will take effect in the quarter commencing Jan. 1, 1906.

London County Council.—On Tuesday it was agreed to lend the Battersea Borough Council £10,891 for electric light installation, and the Southwark Borough Council £5,942 for electric lighting purposes. The Highways Committee recommended that the agreement with the London Electric Supply Corporation for the temporary use by the Council of the company's premises at Deptford, and for the supply of steam from the company's boilers for working the Council's plant installed there, be cancelled, and that an amended agreement be entered into with the London Electric Supply Corporation for the supply to the Council, for a period of three years, of electric power to the Greenwich electricity generating station, where it will be measured, with a minimum of 1,500,000 units a year, at a price for the first 2,000,000 units of 1d. per unit, and for any quantity beyond that amount of ·75d. per unit, and that the agreement be subject to the company holding sufficient plant at the disposal of the Council to allow of a maximum demand of 1,500 kw., and purchasing the plant installed by the Council at the Deptford station for the sum of £13,000. Notices under Electric Lighting Acts and Orders were agreed to as follows: from the Brompton and Kensington Electricity Supply Co., high and low tension mains along Courtfield-gardens; Charing Cross, West-end, and Electricity Supply Co., mains along and across a portion of Chancery-lane; County of London Electric Supply Co., high and low tension mains along New North-street and mains along Hotham-road; London Electric Supply Corporation, low-tension mains along a portion of the Strand and high and low tension mains in Evelyn-street, New King-street, and Prince-street; Metropolitan Electric Supply Co., low-tension mains along a portion of Sandland-street; Notting Hill Electric Lighting Co, mains along a portion of and across Boundary-road and across Latimer-road; South Metropolitan Electric Light and Power Co., low-tension mains along a portion of Hyde-vale and construct two transformer boxes at the junction of Wemyss-road and Montpelier-vale.

Torquay.—Proposals from the National Electric Construction Co., the contractors for the tramways, for leasing or purchasing the existing electrical undertaking of the Corporation have been referred to the Electric Lighting Committee. The Local Government Board have informed the Council, in reference to the recent inquiry into the application for sanction to borrow £9,500 for the extension of the electric lighting and power station, that they would sanction the borrowing of £8,099, and they had deducted the following sums: cost of taking down and removing 125 kw. alternator, £10; outstanding debt on such alternator, £1,356; cost of removal of 40-kw. alternator, £55—total, £1,401. As regarded the first and third deductions, the Board did not regard these items as suitable subjects for a loan. The deduction of the second item was made in accordance with the Board's usual practice in cases where works on which debt was outstanding were to be superseded. They raised no objection to the application of any sum received from the sale of the 125-kw. alternator in defraying the cost of the new plant. At the same time the Board pointed out the desirability of postponing for the present any extension of the system of public lighting by electricity. They gathered that this system was unremunerative, and, having in view the financial advantage of utilising the present generating station as long as possible, it was clearly inadvisable to increase the existing load for any unprofitable purpose. Moreover, the Board considered that, as the provision of a new generating station would, no doubt, ultimately be necessary, the Town Council should see that the undertaking was carried on with the greatest economy, and otherwise in such a manner that a substantial reserve fund might be built up to meet the anticipated large expenditure. The town clerk added that the loan had to be repaid in 15 years. Mr. Mortimer, in moving that the Local Government Board's letter be referred to the Electric Lighting Committee, said no doubt a certain amount of gratification was felt that the loan had been granted. At the same time, he thought, with those who advocated the larger scheme, that this scheme, with certain modifications, was preferable to the present one. The motion was adopted.

Dumbarton.—The contractors for the electricity works are now at work. The agreements entered into by the Electric Supply Corporation and Messrs. Crompton and Co. provide not only for a supply of electricity for lighting and power purposes throughout the town, but also for a system of electric tramways. The contract for mains has been given to Messrs. Callender's Cable and Construction Co. The Electric Supply Corporation have purchased a large plot of ground near the railway, and comprising an area of 1¾ acres, and the plans for the generating station have been passed by the Dean of Guild Court. The buildings will consist of an engine-room, boiler-house, battery-room, pump-room, stores, and offices. Provision is made for future extensions, and designs for the car-sheds, which will occupy a portion of the site, are now being prepared. The electric generators will consist of two 200 kw. and one 50-kw. Crompton dynamos, each direct coupled to a Belliss engine. The engines will be compound high-speed fitted with forced lubrication and working with superheated steam at a pressure of 180lb. per square inch. The auxiliary machinery will consist of automatic balancers and boosters, together with the necessary switchgear. For the tramway service a special Crompton-Mackintosh booster will be provided in order to work the tramway storage battery to the best advantage. Two A.B.P. accumulator batteries will be provided, one for the tramways and the other for the general supply. Each battery will have a capacity of 420 ampere-hours. The boiler-house plant will consist of two Babcock and Wilcox land-type boilers, each capable of evaporating 6,000lb. of water per hour under normal conditions. Provision is being made in the boiler-house for thermal storage tanks, but these will not be supplied in the first instance. The boilers will be fitted with mechanical chain-grate stokers, and the feed water will be driven by electrically-driven pumps. The supply will be continuous current at 240 volts for lighting and small motors, and 480 volts for large motors, etc. Current for private lighting purposes will be supplied at 4½d. per unit. The detailed survey and drawings of the tramways work have been completed, and the contracts for the work will be placed in the course of the next few days. They will be on the overhead system, and cars, etc., will be on the Glasgow model. The tramways in the burgh are the beginning of a larger scheme for carrying a through route from Balloch to Clydebank, for which the Electric Supply Corporation intend to obtain parliamentary powers.

Leicester.—An interesting report on the Leicester gas and electric light undertakings, their history and remarkable progress, by Councillor E. Edwards (chairman of the Municipal Gas and Electric Light Committee), appeared in the *Leicester Daily Post*, in which the author deals with the latter undertaking as follows: "The Leicester Corporation Act of 1879 authorised the Town Council to apply £20,000 of

Digitized by Google

gas capital during a period of five years, to be repaid within 10 years of borrowing, to the lighting by electricity of streets and places of public resort. No action was taken under this authority, and it was not until the year 1889 that the Leicester Town Council decided to apply for a provisional order to empower them to supply electricity under the Electric Lighting Public Act of 1882. The Electric Lighting Orders Confirmation Act of 1890 gave the necessary permission. The whole borough was described as the area of supply, with a 'limited area,' comprising the centre of the town, duly set out. In July, 1892, schemes and tenders were invited for the electric lighting of the 'limited area.' Twenty-five tenders were submitted to the Gas Committee, and the engineer and manager, Mr. Alfred Colson, M.I.C.E., was instructed to report upon them. He was unable to recommend any for adoption; but competitors were allowed to modify and improve their scheme upon lines placed before them. Two which most fully embodied the conditions with which he considered any selected scheme should comply were recommended to the committee. Of these, that of the Brush Electrical Co. was accepted. On April 25 the Town Council unanimously adopted the recommendation of the Gas Committee. The system decided upon was the high-tension alternating current, with street transformers and low-tension distribution, and with the central station placed on the Aylestone-road gasworks. Generating plant capable of producing 875 kw. was erected there. Current was first supplied to the town on Dec. 19, 1894. The undertaking developed, and its business steadily increased. The consequence was that in 1897, 1900, and 1904 application had to be made for further capital. In 1897 the induction type of alternator was adopted, with the most satisfactory results. The capacity of the central station has been increased until it is now equal to 4,400 kw. The price charged for current at first, 6d. per unit, was reduced in 1897 to 5d., and in 1899 4½., 2d. per unit being charged for power purposes. The length of cable laid is 85 miles, 36 of which are high-tension and 49 low tension. The total expenditure on capital account to June 30 last was £254,915. Care is taken to maintain the plant and cables thoroughly up to date. The sum of £40,900 has been paid in interest; £35,000 to sinking fund account, and the balance of net profit in hand at June last was £14 515. There are 2,537 consumers, with an installation equivalent to over 215,000 8-c.p. lamps. Many thought that street-lighting by electricity would be undertaken by the Corporation. But the Gas and Electric Lighting Committee have been strongly opposed to it, believing that incandescent gas is far superior both as regards efficiency and cost. The wisdom of the policy has been thoroughly justified, not only by the fact that the authorities of most Continental cities are now adopting the same policy, but by the circumstance that the city of London authorities have decided to substitute incandescent gas lighting in even those streets where electric lighting has been in use for a considerable number of years. When the electric light was first introduced some thought gas was doomed. Instead of this, electricity has been the best friend gas ever had, because it has been put upon its merits. It has thus improved its lighting capacity, has sought other spheres of usefulness, such as cooking, heating, and power. The result has been that wherever the electric light has been introduced, the consumption of gas has increased by leaps and bounds. The Leicester Town Council were wise in placing the development of both illuminants in the hands of one committee, thus preventing friction that might otherwise have arisen. The committee also are fortunate in having in their service an official who is not only in the front rank as a gas engineer, but also an exceedingly capable electric engineer. The great success of the combined undertaking has thus been due to one master mind that has directed the whole. It is my sincere hope that this happy combination will always continue."

Durban.—The report of Mr. John Roberts, the borough electrical engineer, for the municipal year ending July 31, 1905, states that, notwithstanding the commercial depression, which, as reflected in the business of the department, has been more severe than in any previous year since the commencement of the undertaking, last year's working showed satisfactory results. The following shows the extension which the business has undergone: number of private consumers of electric light—year ending July 31, 1905, 2 936 (year ending July 31, 1904, 2,441); number of private consumers of electric power, 171 (140); number of street arc lamps, 255 (230); number of street incandescent lamps, 1,240 (802); number of units sold, 4,419,651 (3,787 675); total revenue, £76,702 (£69,052). During the year the price was reduced by 10 per cent. in the form of discount for prompt payment, and this substantial discount has been the means of bringing the revenue in very promptly, and this is well illustrated by the fact that on July 31 last the amount of outstandings was £3,152, as compared with £4 735 at the end of the previous financial year. He strongly recommends that future reductions be made in the form of increased discounts, and that the figure of 8d. per unit be kept as a standard on which all future reductions should be made. This course is rendered advisable, if not absolutely necessary, by the fact that as the number of connections increases, and as the electric light extends into the residences of the poorer classes, the average account will continue to decrease, and the work of collection of the large number of small accounts every month will become so troublesome and expensive that, at the low price at which it is hoped to supply current, every means must be taken to induce customers to pay promptly, and reduce the labour and expense of dealing with arrears, and reduce the loss from bad debts. The power business has suffered most from the depression in industrial undertakings, and the revenue from this source has actually decreased, although the department has made a gain owing to the demands which have been made by other departments, chiefly the water department. So successful have been the results of the application of electric motors to the work of sewerage and water pumping that the borough engineer is shortly to convert the existing steam pumping plant at Florida-road reservoir to electricity, and it is expected that greater efficiency and economy will result. The greatest increase in street-lighting has taken place on the Berea and other residential parts, and there are now few thoroughfares of any importance which are not illuminated. The work is still going on, however, and during the present year Mr. Roberts hopes that most of the remaining oil lamps will be superseded, and that it will be possible to reduce the charge for these incandescent lamps from £3 per annum each to £2. 10s. The net profit account shows profits as follows: street-lighting, £244; motive power supply, £794; private lighting, £13,335—making a gross total of £14,374; subtracting a loss on tramway current supply, £622—total profit, £13 752. The following table gives a comparison of the cost per unit generated in the power station for the years 1903 4 and 1904-5: units generated year ending July 31, 1905, 5 157,135 (year ending July 31, 1904, 4,348 914); coal £15 491, ·72d. (£14,151, ·77d.); oil and waste, £773, ·04d. (£762 ·04d.); water, £670, ·03d. (£750, ·04d.); wages, £4,548, ·21d. (£5,055, ·28d.); repairs, £2,201, ·10d. (£2,318, ·13d.)—totals, £23,683, 1·10d. (£23,036, 1·26d.). Mr. Roberts promises still further reductions in the cost of production, and says: "A large expenditure may be necessary to effect the economies I look forward to. These economies lie chiefly in the direction of saving coal. The expenditure account shows that this item amounts to nearly half the total cost of production, and the labour in handling over 42 tons per day cost almost exactly £1,000 per annum. I am now carefully experimenting on mechanical stokers, and the results so far obtained seem to show that it will be profitable to add them to all the boilers as soon as possible, and to put in a conveyor to automatically carry the coal to these machines. I hope, therefore, to ask your permission to purchase this plant and instal it without delay. The following is a list of the amounts spent under the various chief items of capital expenditure: power station, wages £1 639, material £ 0 453—total, £12,093; underground mains, £679, £3,646—£4 325; overhead mains, £830, £2 681—£3,511; sub stations £480, £956—£1,176; house services (chiefly meters), £1,196, £1,874—£3 070; street-lighting, £345, £803—£1,148; sundries, £116, £258—£374; totals, £5,026, £20,671, £25,697. The principal works involving the above sums are enumerated and described as follows: The power station—the purchasing and fixing of a large battery from the Tudor Battery Export Syndicate absorbed approximately £4,000 of the amount under power-station construction. This battery was erected very expeditiously, and has so far given very good results; and by its use great economy in coal is expected to be obtained. A large item of £2,166 was paid to Messrs. Dick, Kerr, and Co. as a final payment on their contract with us, which has extended over three years, and was paid for machinery actually supplied during the previous year. A proportion of the payment on two large boilers and two chain-grate stokers is also included. The remainder has been spent on completion of building, fixing of new economiser, improvements in the boiler-room, improvements on the switchboard, etc., which have been made with a view to increase economy of operation. Underground mains—The following list shows the number of miles of mains laid during the year, and also the total to date: cable for motive power, total miles on July 31, 1904, 11·372, miles added during year ·420; cable for tramways, 17·223, ·002; street arc lighting, 15·000, ·030; high-tension cable for private lighting, 41·292, 1·358; low-tension cable for private lighting, 24·007, 1·698—total, 1904, 108·894, total added 3·488. Total miles on July 31, 1905, 112 382.

PROVISIONAL PATENTS, 1905.

Nov. 20.

23863. An advertising device for electrical station indicators. Josef Esser, 51, Hohenzollernring, Cologne s/Rh., Germany. (Complete specification.)

23878. Locking device and electric coupling for arc lamps and the like. Johann H. Bastians, Crest, Kenley, Surrey. (Date applied for under Patents Act, 1901, Jan. 6, 1905, being date of application in Germany.) (Complete specification.)

23889. Improvements relating to automatically cutting off the current from electrically heated furnaces, stoves, or other apparatus at any desired temperature. Henry Edward Newton, 6, Bream's buildings, Chancery-lane, London. (Klewe und Co. G. m. b. H., Germany.

23894. Improvements in and relating to electric switches. The British Thomson-Houston Company, Limited, and John Malcolm Wallace, 83, Cannon-street, London.

23904. Improvements in connection with monophase electric motors. Felten und Guilleaume-Lahmeyerwerke Act.-Ges., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Nov. 21, 1904, being date of application in Germany.) (Complete specification.)

23934. Improvements in or relating to electrical distribution systems. Alfred Julius Boult, 111, Hatton-garden, London. (J. Lester Woodbridge, United States.) (Complete specification.)

Nov. 21.

23976. Improvements relating to combined electric motors and air compressors. The Phœnix Dynamo Manufacturing Company, Limited, and Robert Pohl, 322, High Holborn, London.

23997. Improvements in electric telegraphs. Siemens Bros. and Co., Limited, and George Sylvester Grimston, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

24024. Improvements in means for controlling self-exciting generators. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Digitized by Google

24025. Improvements in and relating to vapour electric apparatus. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Nov. 22.

24058. Improvements in elastic suspension devices for the electric motors of tramcar and like trucks. Montague Brown Mountain, Godfrey Maesien Gibson, and Arthur Falkland Howard Head, 55, Market-street, Manchester.

24061. Improvements in electric arc lamps. Henry Bevis and Arthur Ernest Angold, Peel Works, Adelphi, Salford, Manchester.

24106. Improvements in operating rotating apparatus by means of single-phase commutator electric motors supplied for polyphase circuits. Rudolf Braun, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London.

24139. Improvements in magneto or dynamo-electric machines. Henri Guillon, 40, Chancery-lane, London.

24141. Improvements in dynamo-electric machines. The Hon. Charles Algernon Parsons and Alexander Henry Law, 18, Southampton-buildings, Chancery-lane, London.

Nov. 23.

24158. A prepayment mechanism and switch in connection with the prepaying of rentals or instalments for hire purchase, in respect of apparatus or wiring in connection with installations of electric light, heat, or power. Francis Henry Merritt, Acristo, Wells-street, Ryde.

24162. Improvement in obstruction removers applicable to electric tramcars or the like. John Richard Hudson, 17, Haymarket, Sheffield.

24178. Improvements in ships' telegraphs and like instruments. James Eggleshaw, 65, Chancery-lane, London.

24183. Improved controller finger contact for electrical work. Francis Ernest Imeson, 8, Wilson-street, Thornaby-on-Tees, York.

24184. An automatic life-guard or cut-out for overhead wires. James E. Newton, 42, Raphael-street, Halliwell, Bolton.

24187. Improvements in apparatus for the control of electro-magnetic power hammers, drop stamps, presses, and the like. Thomas Henry Large, 154, St. Vincent-street, Glasgow. (Complete specification).

24189. An improved means and apparatus therefor for preventing the hoisting rope or wire from damaging the electric cables in an arc lamp column or the like. Ernest Charles Lea, 18, Fulham-place, Paddington, London.

24197. Improvements in or connected with the control of electric motors used in connection with secondary or storage batteries. Willis Nelson Stewart, Alderman's House, Alderman's-walk, Bishopsgate-street, London.

24200. Improvements in devices for electrically lighting inverted gas-burners. Paul Benard, 65, Chancery-lane, London. (Date applied for under Patents Act, 1901, Nov. 26, 1904, being date of application in France.) (Complete specification.)

24213. Improvements in make and break apparatus suitable for induction coils. Frederick George Loring, 24, Southampton-buildings, Chancery-lane, London.

24235. Improvements in electric motor-controlling devices. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24236. Improvements in and relating to electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24240. An improved bracket for supporting electric lights and the like. John Dingle Adams, 28, New Bridge-street London.

Nov. 24.

24249. Improvements in and relating to electrical contact breakers of explosion engines of motor vehicles. Walter Joseph Charles and Alfred Watson, 11, Burlington-chambers, New-street, Birmingham.

24268. Improvements in the section and form of conduit in the method of laying it in connection with tramway rails and placing within it an electric conductor and in the manner of applying a brush or pulley from a car to the said electric conductor. Henry James Peddle, 14, Fountainhall-road, Edinburgh.

24280. Improvements in electric interlocking of railway signals with block telegraph instruments. William Robert Sykes, jun., Frederick Thomas Hollins, and Frederick William Leake, 96, Fillebrook-road, Leytonstone.

24281. Improvements in electrical block indicators for railway gate crossings. William Robert Sykes, jun., Frederick Thomas Hollins, and Frederick William Leake, 96, Fillebrook-road, Leytonstone.

24293. Improvements in contact-breaking devices for magneto-electric ignition apparatus. Willy Roos, 65, Chancery-lane, London. (Complete specification.)

24316. Improvements in electrical generators or motors. Samuel Jevons, 77, Colmore-row, Birmingham.

24302. Improvements in mechanism for automatically actuating electric switches or contacts or apparatus for regulating the supply of electricity at different rates or for similar purposes. John Meany Tourtel, 146A, Queen Victoria-street, London.

24303. Improvements in switch-releasing mechanism for coin-freed electricity meters. John Meany Tourtel, 146A, Queen Victoria-street, London.

24323. An improved mechanical and electrical register counting entries through turnstiles and the like and recording them at a distance. Alfred Laurence Penniket, 39, Holford-square, London.

24325. Improvements in or relating to electric conductors. Alfred Julius Boult, 111, Hatton-garden, London. (Harry E. Knight, United States.)

24339. Improvements in junction boxes and similar apparatus for the connection of electric cables or the like. Arthur Trevor Dawson and Albert Periam Pyne, 7, Southampton-buildings, Chancery-lane, London.

Nov. 25.

24383. Improvements in electric switches. John Arthur Hirst and Percy Smith Brook, Northgate Electrical Works, Victoria-road, Chester.

24403. Improvements in apparatus for controlling electric circuits. The British Westinghouse Electric and Manufacturing Company, Limited, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (The Westinghouse Electric and Manufacturing Company, United States.)

24421. Improvements in dynamo-electric machines. Ludwig Torda, 40, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 14.

1904.

22443. Combined telephone and sounding telegraph. Andersson.

25026. Electric switch-operating mechanism. British Thomson-Houston Company, Limited. (General Electric Company.)

25027. Electric switch-operating mechanism. British Thomson-Houston Company, Limited. (General Electric Company.)

25370. Method of utilising the live wires of an electric lighting and like circuit to convey signals by the aid of electric waves. Lee and Bottone.

25519. Electric incandescent candle lamps. Dafforn.

25645. Space telegraphy. Stone. (Date applied for under International Convention, Nov. 25, 1903.)

25682. Arc lighting lamps. Andersson. (Date applied for under International Convention, Nov. 30, 1903.)

25784. Means for regulating electric circuits. Leitner and Lucas.

26169. Fusible electric cut-outs. British Thomson-Houston Company, Limited. (General Electric Company.)

27869. Construction of lock and electrical contact maker and breaker for lifts. Burnett and Richmond.

28546 Protected or armour-clad electric switch fuses. Berry.

28840. Self-acting electric motor-starting rheostat. Hirst and Brook.

29607. Liquid resistances for controlling the current in electromotors and the like. Bruce Peebles and Co. Limited, and Peebles.

1905.

3171. Electric motors and dynamo-electric machines. Vickers, Sons, and Maxim, Limited, and Williamson.

4166A. Improvements in induction coils. Bines. (Date applied for under Rule 5, Patents Rules, 1905, Feb. 28, 1905.)

4273. Apparatus for automatic electric advertising and like purposes. Fricker.

4715. Electric insulators. Cushing.

7591. Alternating-current dynamo-electric machines for synchronising and connecting them with distributing conductors. Johnson. (Voight und Haeffner, Akt.-Ges.)

8652. Plug boxes and the like for the connection of electric conductors to the main supply cables. Kirk and Corlett Electrical Engineering Company, Limited.

9344. Electric current motor. Kruyswijk. (Date applied for under International Convention, May 5, 1904.)

11441. Device for limiting the speed of compensated single-phase alternate-current motors. Elektrizitäts Akt.-Ges. vorm. W. Lahmeyer und Co. (Date applied for under International Convention, July 30, 1904.)

13327. Responders for wireless telegraphy. Hancock.

13570. Electric switches for coin-freed mechanisms, time switches, or the like. Siemens Bros. and Co., Limited. (Siemens Schuckertwerke G. m. b. H.)

13703. Dynamo-electric machines. British Thomson-Houston Company, Limited. (Allgemeine Elektricitäts-Ges.)

13953. Electrical recording devices. Harrison. (Electric Railway Improvement Company.)

14314. Microphone apparatus for telephone and other circuits. Majorana.

Digitized by Google

14222. Suspension of electric motors of locomotives and other electrically-propelled vehicles. British Thomson-Houston Company, Limited. (General Electric Company.)

15055. Process for extracting metals from ores and other metalliferous material by electrolytic means and apparatus therefor. Garz und Co., Eisengiesserei und Maschinen-Fabriks Act.-Ges. (Date applied for under International Convention, Aug. 26, 1904.)

15836. Electric wiring. Yorke.

16024. Telephone office systems and methods of establishing connections therein. Lean. (Deutsche Telephonwerke R. Stock und Co. G. m. b. H.)

16357. Arc lamps. Blondel.

16397. Disengaging mechanism for the controlling devices of shunt circuit arc lamps. Efrém and Sidler.

17032. Electrically-operated fans. Thompson. (Firm Reiss und Klemm.)

17084. Electric train lighting systems. Siemens Schuckertwerke G. m. b. H. (Date applied for under International Convention, Aug. 25, 1904.)

17243. Electricity meters. Aron.

18401. Continuous-current dynamo-electric machines. Siemens Bros. and Co., Limited. (Siemens Schuckertwerke G. m. b. H.)

19116. Machine for electrically welding metal wires, cables, hoop-irons, and the like. Rolland.

20058. Method of winding revolving field magnets. Siemens Schuckertwerke G. m. b. H. (Date applied for under International Convention, Nov. 12, 1904.)

20100. Rontgen-ray tubes. "Polyphos" Elektrizitäts-Ges. m. b. H. (Date applied for under International Convention, Oct. 5, 1904.)

20898. Electrolytic apparatus. Rüber. (Date applied for under International Convention, Oct. 15, 1904.)

NOTES.

Nottingham Guild.—Mr. G. Preece, of Manchester, has promised to read a paper on "Electric Cables" before the members of the Nottingham Guild of Mechanical and Electrical Engineers. The chair will be taken by Mr. H. Talbot (city electrical engineer). Among the papers arranged for the session is one on "Iron Manufacture" by Mr. J. Crawford, while other members of the guild have promised to contribute papers. The annual dinner will take place on March 13, 1906.

Milan Exhibition.—At a recent meeting of the British section of this exhibition the following gentlemen were elected on the commission: the Right Hon. the Earl of Glasgow, G.C.M.G., Sir Philip Watts (the Admiralty), Sir Alexander Binnie, Sir Thomas Wardle (Leek), and representatives of the Manchester Society of Engineers, the Iron and Steel Institute, and the British Chamber of Commerce for Italy (Genoa). The commission have appointed "Executive" and "Juries" Committees, and approved the Finance Committee previously formed.

Physical Society.—An exhibition of electrical, optical, and other physical apparatus will be held next Friday evening, Dec. 15, from 7 to 10 p.m., at the Royal College of Science, Exhibition-road, South Kensington. The meeting was originally arranged to take place this evening, but has been cancelled. Among the firms exhibiting apparatus will be Messrs. Crompton and Co., Messrs. Elliott Bros., Messrs. Everett, Edgcumbe, and Co., Messrs. James Pitkin and Co., Messrs. Nalder Bros. and Thompson, and others. Admission will be by tickets only, which may be obtained through any of the Fellows of the society.

New York Electrical Society.—The centenary of the birth of Benjamin Franklin (Jan. 17, 1906) is to be celebrated with much distinction in the United States. Owing to the number of functions on hand for the evening of that day, the New York Electrical Society (the oldest electrical society in America) has decided to hold its "Franklin Night" on the 16th. Mr. Marconi has expressed his desire to render his tribute to the memory of the great electrical inventor, and his address has, therefore, been fixed for that evening. The occasion should be of great interest, in view of the recent progress made in wireless methods in America.

Iron and Steel Institute.—The council have arranged that the annual general meeting of the institute shall be held in London on May 10 and 11, 1906. In place of the usual autumn meeting, a joint meeting with the American Institute of Mining Engineers will be held in London on July 23 to 28. It is intended during the week following to give the American visitors an opportunity of seeing some of the ironmaking districts. It is anticipated that the visiting party will include many of the leading ironmasters who entertained the Iron and Steel Institute in America in 1890 and 1904. The Lord Mayor of London has kindly consented to act as chairman of the London Reception Committee, and to give an evening reception at the Mansion House.

Siamese Tramway System.—On the occasion of the opening of this system, which took place in October last by his Majesty the King of Siam, the directors presented an address to his Majesty in which were given details of the work carried out. The overhead wire system has been adopted, with two trolley wires, on one of which runs the up car and on the other the down car. By the introduction of this feature the directors hope that wear and wear will be greatly reduced, and the possibility of breakdown and stoppage of traffic removed. The power station is fitted with the most modern plant, amply sufficient to deal with all the traffic that can come upon the line. The total length of the track is about 19·10 km., and has occupied 18 months in construction.

Witham Railway Disaster.—Lieut.-Colonel von Donop's report to the Board of Trade on the disaster which occurred on the Great Eastern Railway on Sept. 1 states that the cause was not any defect in the rolling-stock. Though the findings of the inquiry do not call for any special observations on our part, we think that the concluding sentence of the report is worthy of special attention. One of the carriages was destroyed by fire owing to the ignition of gas in the cylinder underneath the framework, and this occurrence, says the report, "points to the desirability of adopting some other source of illumination, probably electricity." The disastrous consequences of an accident cannot be but seriously aggravated when to it are added the horrors of fire, and, as a necessary precaution, the system of lighting by gas must yield to the safer system of electric lighting.

Teltow Canal.—Electric traction on the Teltow canal, which is one of the principal canals in Germany, is about to be applied on a large scale, in accordance with a programme formerly decided upon. It will be remembered that a number of experiments with different forms of tractors were made along the canal, and these showed that the electric system offered many practical advantages. A large central station for supplying the current has been erected, which contains a 400-h.p. dynamo and engine group and two large steam-turbine and dynamo sets of 700 h.p. each. The station is now prepared to furnish current. The extensive system of locks will first have an electric system for operating it. The rails for the electric locomotives have been laid along the canal in the eastern section between Grünau and Britz, on both banks. The overhead wires and the poles are being put in place, so that it will not be long before the locomotives will be ready to haul the canal boats.

Engineering Standards Committee.—This committee, acting at the request of the Secretary of State for India, instructed the Locomotive Committee to consider the questions of the most suitable designs of locomotives for use on the railways of India and the standardisation of their component parts. The report of this committee, signed by Sir Douglas Fox, chairman, and Mr. Leslie S. Robertson, secretary, has just been issued, and contains a list of instructions to designers, based upon the findings of a conference of consulting engineers and locomotive builders. A number of plates are given describing the design of the proposed passenger engine and tender and goods engine and tender for the 5ft. 6in. gauge and metre gauge. The committee have also been requested to consider the advisability of standardising three more types of broad-gauge locomotives of a heavier class than those dealt with in the present report, and they are now giving their consideration to this request. The report may be obtained from the secretary, Mr. Leslie S. Robertson, at the offices of the committee, 28, Victoria-street, Westminster, S.W., at the price of 10s. 6d. net.

Pacific Cable.—The present position of the negotiations in connection with the Pacific Cable indicates a deadlock. At the Imperial Conference which was held in London four or five months ago a committee was appointed to see if a pooling arrangement with the Eastern Company was possible, on the understanding that the agreement with New South Wales, which is held to operate against the Imperial undertaking, is modified in some way. The

Digitized by Google

terms of the company were obtained and submitted to the Governments of the various countries concerned—namely, Great Britain, Canada, Australia, and New Zealand. It is understood that New Zealand has declared against any pooling arrangement, and so far the other Governments have taken no steps towards coming to an arrangement, Australia having not officially ratified in any way the action of Lord Jersey, its representative at the conference. There the matter rests, and at present there is little prospect of anything further being done. In the event of the position remaining unchanged by next month, the Pacific Cable Board, it is understood, proposes to open new offices in Australia, thus coming into direct competition with the private concern.

Obituary.—We regret to record the death of Sir Henry Charles Fischer, C.M.G., late controller of telegraphs, which took place on Thursday of last week at Southover, Bromley, Kent, in his seventy-third year. Sir Henry was born and educated in Germany, and in 1852 entered the Hanoverian Government telegraph service. He came to England in 1856 and entered the service of the Electric and International Telegraph Company. At the transfer of the telegraph to the State in 1870, he was deputed by the Postmaster-General to organise the staff and other arrangements of the Central Telegraph Office of the General Post Office, and he was for many years controller of the department before his retirement in February, 1898 In 1877 he went to America with Sir William Preece, then engineer-in-chief to the Telegraph Department, and they brought back with them the first pair of telephones. Another result of their visit was the introduction into this country of reading by sound as well as of quadruplex telegraphy, by means of which four messages could be sent simultaneously over the same wire in opposite directions. In 1898, the year of his retirement, he received a knighthood, while decorations in recognition of his services were conferred upon him by various foreign monarchs. He also received the Diamond Jubilee medal in recognition of special services in connection with the arrangements for the transmission of Queen Victoria's message to all parts of the world on Diamond Jubilee Day. Sir Henry was a director of the Eastern Telegraph Company.

Indian Telegraphs.—The record of the Indian Telegraph Department for 1904-5 is very satisfactory from every point of view. The administration report announces that the receipts from all sources exceed those of the previous year, whilst the number of departmental offices has also considerably increased. During the year, 1,992 miles of line and 15,419 miles of wire were added, making the length in all 61,684 miles of line and 227,419 miles of wire. It is of interest to learn from the report that communication by means of wireless telegraphy was established in October, 1904, between Diamond Island and Port Blair. The first two months were spent in erecting 150ft. masts and installing the oil-engines and dynamos at Diamond Island, Upper Island, and Port Blair—a distance approximately of 300 miles—on Feb. 10, 1905, since which date communication between those places was maintained regularly, with a few brief interruptions, to the end of the year. The installation is now working perfectly. The report further states that Wheatstone's automatic apparatus was installed in the Mandalay office, raising the number of offices with this apparatus to 15, three of which are translation offices only. Arrangements have practically been completed for fitting up new storage cells and motors in the Bombay central office, and for refitting the office with electric lights and fans to be operated by current supplied by the Brush Company. The installation in the Allahabad office of oil-engines, dynamos, and accumulator cells was commenced in March of this year, and has now been completed. The whole of the work of the department during the year was admirably carried out and gained approval.

Books Received.—We have received from Messrs. Archibald Constable and Co., London, a copy of Mr. J. D. Henry's history of "Baku" (12s. 6d. net). The author describes the origin, early history, progress, and condition of the Russian oil industry up to the time of the massacres in September. The book contains a mass of statistical, trade, and technical information of unquestionable value to oil men, and at the same time is sufficiently general in its scope to be of interest to all who are attempting to follow the sensational events at Baku and other parts of the Caucauses. Sir Boverton Redwood contributes an introductory note to the book, which contains numerous illustrations and a map of the oil fields.—"Alternating Currents," by Alfred Hay, D.Sc., M.I.E.E. (Harper and Bros., London. 6s. net.) In this work Prof. Hay attempts to furnish a general account of the principles, construction, and use of alternating-current measuring instruments, generators, motors, and transforming machinery. Special attention is devoted to methods of testing. The book contains a large number of diagrams and a copious index. The *Proceedings* of the American Institute of Electrical Engineers (vol. xxiv., No. 11, November, 1905) contains a paper by Mr. N. J. Neall on the "Performance of Lightning Arresters on Transmission Lines" and a discussion on "Air-Gap Flux in Induction Motors."—The November issue of the *Journal* of the Chemical Society contains contributions by Dr. J. Wade on the "Influence of Water and Alcohols of the Boiling Point of Esters," and by Mr. H. O. Jones on the "Stereoisomerism of Substituted Ammonium Compounds," together with other papers and abstracts.

Electric Brakes.—On many street railways it has been found that the hand-brake does not satisfy all modern requirements, and the question arises as to the most efficient braking system with which it may be superseded. Some have advocated the adoption of electric brakes, whilst by others preference is shown for use of air-brakes. Advocates of these types took the opportunity of expressing their views as to the merits of their respective systems at the tenth annual meeting of the German Street and Interurban Railway Association, when papers were read by Mr. Scholtes, manager of the Nürnberg Street Railway system, in favour of the use of electric brakes, and Mr. Bjorkegren, whose paper dealt with the subject of air-brakes. Mr. Scholtes pointed out that, as a result of several years' experience, definite conclusions had been arrived at which proved the superiority of the electric brake. Statistics were produced which showed that in Germany 49 per cent. of the street cars were equipped with electric brakes, 31 per cent. with hand-brakes, and 20 per cent. with air-brakes. Of the railway companies who expressed themselves as opposed to electric brakes, it was found that the electrical equipments were not suited for electric braking, though the difficulty could be avoided by selecting apparatus of larger capacity. The maintenance charges of the electric brake per car per annum amount to £2. 10s. The cost of maintenance per car per annum of air-brakes for motorcar and trail car amounts to about £10. The first cost of the electric brake is even less than that of the air-brake, which is £4. 5s. per car per annum. The average additional cost of a larger controller and more closely graduated resistances required by electric braking is about £14 for motorcars and £18 for trailers. As a result of extensive inquiries Mr. Scholtes has ascertained that the solenoid brake is now considered preferable to the disc type.

Electrolytic Oxidation of Hydrocarbons.—An abstract of the observations of Mr. Herbert Drake Law and Mr. F. Mollwo Perkin on the electrolytic oxidation of the benzene series is contained in the November issue of the *Journal* of the Chemical Society. The chief product obtained by the oxidation of ethylbenzene in sulphuric acid solution containing acetone, using a current density at the anode of 1·3 amperes per square decimetre was phenylmethyl carbinol; phenylethyl alcohol was also found in small quantity, and benzaldehyde made its appearance when the number of ampere-hours was more than sufficient to oxidise the whole of the hydrocarbon to alcohol. When oxidised under the same conditions, cymene gave rise to cuminaldehyde and a mixture of mono- and di-hydric alcohols. The carbazone derived from the aldehyde was prepared; it crystallises in pearly plates, melting and decomposing at 206deg. to 208deg. When cumene boiling at 155deg. to 158deg. was oxidised with an anode density of 1·66 amperes per square decimetre, a mixture of cuminaldehyde and hydratropaldehyde and a mono- and a di-hydric alcohol was obtained. These experiments confirm the results of earlier experiments carried out with toluene and the xylenes, and indicate that certain groups, for example, the aldehyde group, are relatively stable when acted upon electrolytically. The protective action exerted by a negative group is illustrated by the oxidation of cymene, the *iso*propyl group not being attacked to any appreciable extent until the methyl group has been completely converted into the aldehyde group. The conclusion is drawn that the active oxidising agent in the electrolysis of dilute acid and alkaline solutions is the hydroxyl group and not oxygen. Even in acid solution, in consequence of the greater mobility of the hydroxyl ions, there is a tendency for these to concentrate around the anode.

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on Monday, Sir James Crichton-Browne, M.D., F.R.S. (treasurer and vice-president), in the chair. Lieut. E. P. C. Amphlett, Mr. F. Bailey, Mr. H. Behrens, Mr. J. Kennedy, Mr. J. N. Kerr, and Dr. E. M. Modi were elected members. The special thanks of the members were returned to Dr. Ludwig Mond, Ph.D., D.Sc., F.R.S., for his donation of £500 to the fund for the promotion of experimental research at low temperatures. It was announced from the chair that the managers had elected Prof. William Stirling, M.D., LL.D., D.Sc., Fullerian professor of physiology. The following are the lecture arrangements at the Royal Institution before Easter: a Christmas course of six illustrated lectures, adapted to a juvenile auditory, by Prof. H. H. Turner, on "Astronomy"; Prof. E. H. Parker, three lectures on "Impressions of Travel in China and the Far East"; Prof. William Stirling, six lectures on "Physiology," subject; Dr. J. E. Marr, three lectures on "The Influence of Geology on Scenery" (the Tyndall lectures); Rev. Canon Beeching, two lectures on "Shakespeare"; Mr. Benjamin Kidd, two lectures on "The Significance of the Future in the Theory of Evolution"; Mr. H. B. Irving, two lectures on "The English Stage in the Eighteenth Century"; Mr. Francis Darwin, three lectures on "The Physiology of Plants"; Prof. B. Hopkinson, three lectures on "Internal-Combustion Engines" (with experimental illustrations); Mr. J. E. C. Bodley, two lectures on "The Church in France"; Mr. J. W. Gordon, two lectures on "Advances in Microscopy"; Mr. M. H. Spielmann, two lectures on "George Frederick Watts as a Portrait Painter"; and Prof. J. J. Thomson, six lectures on "The Corpuscular Theory of Matter." The Friday evening meetings will commence on Jan. 19, when Prof. J. J. Thomson will deliver a discourse on "Some Applications of the Theory of Electric Discharge to Spectroscopy." Succeeding discourses will probably be given by Prof. S. P. Thompson, Mr. H. F. Newall, Mr. W. C. D. Whetham, Dr. R. Caton, Dr. Hutchison, Sir Andrew Noble, Bart., Prof. P. Zeeman, Mr. W. B. Hardy, and other gentlemen.

Society of Arts.—The second of a series of four Cantor lectures on "The Measurement of High-Frequency Currents and Electric Waves," by Dr. J. A. Fleming, F.R.S., was delivered at the society's rooms on Monday, Dec. 4. The lecturer said he had lately been considering a new method of representing and delineating an oscillatory spark. A number of photographs had been taken by that method, which showed the details of the oscillatory discharge. One of the points to be noted in connection with the subject, which had an important bearing on wireless telegraphy, was the "decrement," which expressed the rate at which the oscillations in a circuit died away. For all practical purposes the oscillations might be considered to be concluded when the amplitude of the oscillations had fallen to 1 per cent. of the initial value. Another important factor was the damping factor—*i.e.*, the ratio of the resistance to twice the inductance of the circuit. In an ordinary Marconi aerial oscillations were damped out so completely that they died away at about 20, whereas in other circuits there might be hundreds of oscillations. He and other investigators had used a hot-wire ammeter for measuring currents and trains of oscillations whose mean square value ranged from ¼ ampere up to 15 to 20 amperes. For measuring still smaller high-frequency currents a satisfactory method had been designed by Duddell. It was also necessary to investigate the spark voltage. When this final factor was ascertained it was then possible to work out accurately the details of the discharge of a condenser. Turning to the consideration of methods of determining decrement, Dr. Fleming said it was necessary to distinguish between the radiation and the resistance decrement. In the case of wireless telegraphy, the damping of the oscillations was primarily due to the radiation decrement. The subject of determining decrement had been studied by Rutherford and Bjerknes, and a method adopted by Drude capable of application to both open and closed circuits, was based upon the use of a resonance curve. These investigations had a great bearing on the efficiency of a Marconi aerial. The problem in connection with the efficiency of a wireless telegraphy transmitter was to find an improved method of charging. He was inclined to believe that the coil would be given up before long and superseded by some form of electrostatic instrument. At present there was a large dissipation of energy in the coil itself.

Royal Society.—Following an old-established custom, the Royal Society met on St. Andrew's Day (Thursday, Nov. 30) to hold its anniversary meeting and to elect a president and council. Sir William Huggins delivered his valedictory address as president, which dealt largely with the influence which the discoveries of science had conferred upon the general life and thought of the world during the last 50 years. Some instructive and stimulating observations were also made with reference to the place of science in general education. The president then proceeded to the award of the medals. The Copley medal was awarded to Prof. Dmitri Ivanovitch Mendeleeff, F.M.R.S., for his contributions to chemical and physical science. A Royal medal was awarded to Prof. John Henry Poynting, F.R.S., on account of his researches in physical science, especially in connection with the law of gravitation and the theories of electro-dynamics and radiation. The other Royal medal was awarded to Prof. Charles Scott Sherrington, F.R.S., for his work on the central nervous system, especially in

Digitized by Google

relation to reflex action. The Davy medal was awarded to Prof. Albert Ladenburg on account of his researches in organic chemistry, especially in connection with the synthesis of natural alkaloids. The Hughes medal was awarded to Prof. Augusto Righi for his experimental researches in electrical science, including electric vibrations. Prof. Righi had been for many years a prominent and active worker in the sciences of light, electricity, and magnetism. He was the first to announce the very interesting and still imperfectly explained phenomenon that the ultra-violet rays of the spectrum, when they fell on a piece of electrified metal, were capable of causing a discharge of that electricity. The following were elected to serve on the council for the ensuing year: president, Lord Rayleigh; treasurer, Alfred Bray Kempe, M.A.; secretaries, Prof. Joseph Larmor, D.Sc., and Sir Archibald Geikie; foreign secretary, Francis Darwin, M.A.; other members of the council—Shelford Bidwell, Sc.D., Sir T. Lauder Brunton, M.D., Prof. J. Norman Collie, Ph.D., Prof. Wyndham R. Dunstan, M.A., Prof. John Bretland Farmer, M.A., Prof. Francis Gotch, D.Sc., Sidney Frederic Harmer, Sc.D., Sir William Huggins, K.C.B., Prof. Edwin Ray Lankester, M.A., John Edward Marr, Sc.D., George Ballard Matthews, M.A., Hugh Frank Newall, M.A., Sir William Davidson Niven, K.C.B., Prof. John Perry, D.Sc., Prof. Ernest Henry Starling, M.D., and Prof. William Augustus Tilden, D.Sc. In the evening a banquet took place at the Hôtel Métropole, where there were assembled some of the most distingnished representatives of science, jurisprudence, and literature, and over which the new president (Lord Rayleigh) presided.

High-Tension Lines.—The Missouri Power Company claim to have operated a high-tension service of the highest voltage over the longest time. The length of the line extends from the company's power station at Helena to Butte, Mont., a distance of over 65 miles, and during the past 2½ years it has been continuously operating at 55,000 volts. An inquiry into the operation of the system has been made by Mr. Chas. F. Scott, who, in the *Electric Journal*, asserts that the record of the plant for the year has been a remarkable successful one. The service is for 24 hours a day, seven days a week, and the power delivered at Butte for mining and smelting operations shows a very high load factor. The success of this plant is proved by the present plans for extension. A new dam and power-house will be constructed a few miles below the Canyon Ferry plant. The old and new power-houses will be operated in parallel over the present lines to a new sub-station at Butte, and an additional sub-station at Anaconda. The transmission voltage will be increased to 70,000 volts, and the maximum distance of transmission will be approximately 100 miles. The new power-house will contain three banks of raising transformers, each consisting of three 2,000-kw. units. An important adjunct to the system will be a steam-turbine auxillary plant at Butte. During seasons of low water the steam plant will be used to supply power; at other seasons when water power is abundant, the limit of the amount of power transmitted is the capacity of the generators and transmission circuits, the turbo-generator will be uncoupled from the turbines in order that they may run as idle synchronous motors for increasing the power factor of the current from the transmission lines. A brief description of the insulators and pole construction was communicated to the International Electrical Congress by Mr. M. H. Gery, jun. The line cables are composed of seven strands, and have an area of 106,000 circular mils. They are carried along insulators mounted on cedar poles and fir cross-arms. The cross-arms, braces, and pins are held in place by means of through bolts. The pins are prepared by being first dried and then tested in paraffin, until all moisture is removed. The glass sleeves are not fastened to the insulators, and merely rest on a shoulder of the pins. The circuits are transposed five times, making two complete turns between the generating station and the sub-station. The switching operations are such that the circuits may be operated either singly or in multiple. A telephone circuit is located on one of the lines, and gives good results in service. The poles are from 35ft. to 75ft. in length, and the pole tops are from 9in. to 12in. in diameter. The poles are set from 6ft. to 8ft. in the ground, according to height, and the standard spacing is 110ft., with a maximum spacing of 150ft.

Traction Systems.—Traffic conditions on electrically-equipped railways may be divided into three broad classes—viz., short-haul service, long-haul service, and grade work—and their influence on motor specifications was pointed out by Mr. A. H. Armstrong in a lecture at the Brooklyn Polytechnic Institute. In dealing with the relative values of the different types of railway motors, Mr. Armstrong said that the direct-current series motor, though satisfactory, was not as good as one specially designed to fulfil special conditions. The installation of the direct-current shunt motor might be warranted under conditions where its ability to return energy on down grades would be an important factor. The two important characteristics which the three-phase motor has in common with the direct-current motor are that it runs at constant speed and returns energy to the line. In general, however, the three-phase motor possesses qualities which under certain conditions make it preferable to the direct-current series motor. In certain classes of work the single-phase motor is a strong rival of the direct-current series motor. This rivalry is not due to superiority in design, performance, lesser cost, or weight, but because the first-mentioned motor effects certain fundamental changes that greatly reduce the cost of the distribution system and line. Mr. Armstrong mentioned another method of electric operation—namely, by motor-generators, which scheme allows the use of large induction or direct-current motors carried either on the locomotive or in a tender behind. A field for motor-generator operation has been opened up by the application of electricity on the steam trunk lines, necessitating the employment of very heavy and bulky apparatus which cannot be placed under standard passenger cars. Mr. Armstrong then discussed hand, multiple-unit, and alternating-current potential control systems. Hand control, he said, practically reaches its limit when a larger equipment than four 50-h.p. motors is used, mainly because the controller becomes too heavy and bulky for the car platforms. Hence for equipments above this capacity it is better to subdivide the control system, placing the main apparatus under the car, and to actuate the motors through a series of contactors, which may be electrically or pneumatically operated. Alternating-current potential control is becoming the recognised method of controlling single-phase railway motors, the speed depending upon the potential supplied. This method is very economical and simple, the speeds being varied by changing the connections of the car transformer taps. For motor-generator work direct-current potential control is used. A typical speed time run, Mr. Armstrong said, can be considered in several different ways. Taking it up in its fundamental state, it consists of a period of acceleration, a certain amount of free running, and a period of braking. Given intervals must intervene between acceleration, running, and braking, and the all-day duty of the motor consists of a repetition of similar runs.

REVIEWS.

Electric Railways Theoretically and Practically Treated. By SYDNEY W. ASHE B.Sc., and J. D. KELLY. D. Van Nostrand, New York; Archibald Constable and Co., London. Price, 10s. 6d. net.

We are afraid that this book is not suitable for the English market. The publishers' note practically confirms this when it tells us that throughout the American ton = 2,000lb. is used instead of the English ton = 2,240lb. Thus it happens that there must be hardly a single calculation but requires translation. A man has not time in the ordinary way to have to worry out things that are not foot-tons, or tons weight, or pounds per ton tractive effort in his own sense. Nor, again, do we agree with the authors as to the absence of "a modern text-book." That may be so in America, but it does not hold in Europe. We also object to the use of *I* for C. The latter is almost universally used in this country, and it is time that notation and nomenclature used here be standardised. However, if it were not for the continual bother of translating from unfamiliar to familiar, there is much in this book that is excellent.

Telegraphy: A Detailed Exposition of the Telegraph System of the British Post Office. By T. E. HUBERT, A.M.I.C.E. With 509 Illustrations. Whittaker and Co., London. Price, 6s. 6d.

The *Times* mentions the size in inches of, say, the covers of a book. Macaulay in some of his essays mentions dimensions, not from the flattering point of view, but otherwise. If, however, Macaulay had had this book before him, probably the size as well as the contents would have in the flattering sense been pronounced prodigious—prodigious. Over 900 pages of good, solid, scientific, and practical matter. Evidently the book is understood to be so good that its circulation must be extraordinary, and from every point of view it deserves all the success that can come to it. We have often declaimed against examinations being made an end instead of a means. Of course, examinations are necessary, but as usually understood they are to be condemned absolutely. If a master requires a man to take any responsible position, he probably sees a man or men, and puts him or them through their facings to find out if they are competent to undertake the responsibility. The Post Office authorities have to do something of the kind with its would-be employés—hence its examinations. This book is directly practical, and, carefully studied, will fit anyone to face with equanimity the ordeal of showing his fitness for a position in the telegraphic service. At the same time, it is the best text-book we have seen for such as are studying for the City and Guilds Institute examinations. The book is excellently arranged, each chapter exhaustively dealing with its particular subject, the earlier chapters giving the information required to understand the later chapters, which deal with more complicated pieces of apparatus. There is, of course, little new in the purely scientific work, but the whole value of the book

FOR

Electric Light Artisans and Students

(Embracing those Branches prescribed in the Syllabus issued by the City and Guilds Technical Institute).

BY

W. SLINGO and A. BROOKER.

LONGMANS, GREEN & CO.,
39, Paternoster Row, LONDON, E.C.

consists in the clear method of analysing and explaining apparatus, describing the functions of the detailed parts, and the exact work and value of the whole. Those of us who are familiar with the telegraphic work of the past half-century will not be surprised at the enormous collection of apparatus that Mr. Hubert has to describe, but to those who are merely outsiders it would be a revelation to examine the book. It is out of question to enter into detailed criticism—wherever we have tested the information it has not failed, even in such a detail as the use of karri (Australian hardwood) for oak in the cross-arms of poles. The description of apparatus is doubly clear by the extensive use of diagrams, which, again, are very good. Altogether the book is one which should be carefully studied, not only by those who would be but by those who are engaged in telegraphy.

Mechanics for Engineers: A Text-Book of Intermediate Standard. By ARTHUR MORLEY, M.Sc., Senior Lecturer in Engineering in University College, Nottingham. With 200 Illustrations and Numerous Examples. Longmans, Green, and Co., London. Price, 4s net.

If we were asked what was the ideal to be attained by a student in physics, we should probably reply, accuracy of measurement. All books on mechanical subjects treat of measurement, and that which assists the student to gain greater expertness and accuracy is the best. We should give Mr. Morley's book a high position among similar books, in that his definitions are exact, his descriptions accurate, and his examples numerous, and not so much of the catchy character in which some authors seem to delight. Students do not want training in mathematical conundrums, but in plain, straightforward work. When the conundrum comes, they form an exception to the rule, and must be tackled as exceptions. The aim of a good book is to assist the student to employ the information therein in his practical work, and not to make him a clever juggler with figures. We commend this book from another point—"the gravitational system of units has been adopted in the English measures." If a man is going to work in a shop, he is better if familiar with the tools and measures used in that shop, although some idealists may think he ought to know nothing about them, but about something else he is not likely to see or use in practice. Again, we commend the chapter on the elements of graphical statics. Many a man can solve a hard practical problem graphically that would be utterly at sea with any other method. Lastly, we are glad to find Messrs. Longmans have not yet descended to the use of wood pulp paper, which is cheap and nasty, while their productions are of such high quality as will well stand the hard usage of student life.

Elementary Electrical Calculations. A Book suitable for the Use of First and Second Year Students of Electrical Engineering. By W. H. N. JAMES, A.R.C.Sc. (Lond.), A.I.E.E., Lecturer and Demonstrator in the Electrical Department of the Municipal School of Technology, Manchester, and D. L. SANDS, Assistant Lecturer, etc., as above. London: Longmans, Green, and Co. Price, 3s. 6d. net.

A Guide to the Electrical Examinations. By FREDERIC H. TAYLOR, A.M.I.E.E., etc. London: Percival Marshall and Co. Price, 1s. net.

The first-named of these books is well worth the serious consideration of all students. The aim of all studentship is threefold—first, to gain; secondly, to think; thirdly, to utilise. The book of Messrs. James and Sands is an aid to the second and third phase of studentship. In the first place, it systematises the thoughts which should be evolved during the course of teaching, and, secondly, it shows how the information gained can be utilised. A student may think he knows, but he is not equipped for practical life till he can prove that he knows—that is, till he can solve the problems that arise for solution in all practical work. What Messrs. James and Sand do is this: first give the moral derived from the teachers or the text-book preaching, then give a large number of practical examples to test the student in the application of the moral. The method they use is to clearly explain the units used in science and in

practice, then to explain the moral, or, better, the equation by references direct or by indirect analogies that may prove forcible illustrations. Thus, hydraulic analogies are largely used. Altogether, the book with its explanations, its worked examples, and its large number of questions for the student to test his powers upon is one that ought to commend itself wherever a student or students exist. A book of this kind to be of service must accord with the general run of text-books, which, to say the least, are very defective, in that they make much of arrangements that really have been explained otherwise. What is a shunt but a conductor in parallel with another conductor, and what is one conductor in parallel with another but a way of increasing the area of a conductor over a certain length? However, these are matters for text-books. Given the ordinary books as they are, we can hardly conceive a better set of notes and examples than has been furnished by Messrs. James and Sands, and the book, like all Messrs. Longmans' publications, is excellently illustrated and printed.

The little treatise of Mr. Taylor is in a different class, dealing with a different subject. It is intended to give information and hints as to examinations. Hence it tells us of certain examinations—what they are, how conducted and the preparations required; then giving hints or practical examples as to the working of the examination papers. The aid thus given is of great use when the student is entirely self-taught and cannot get the assistance of a master, otherwise the information is of a kind that can at any rate partly be better given orally. The sample answers to questions are good.

The Law and Practice relating to Patents, Trade Marks, and Designs. By DAVID FULTON, Barrister-at-Law. Jordan and Sons, Limited. Third edition.

The third edition of the above work, which has recently appeared, maintains the same high standard of practical utility which characterised the previous editions. The work is divided into three parts—Part I. dealing with patents, Part II. with trade marks, and Part III. with copyright in designs. The statutes between 1883 and 1902 have been codified and consolidated, and any alteration in the earlier Acts is shown in the text by the use of different type—an arrangement which will commend itself to the practitioner by reason of the fact that it will save him considerable time and labour. A similar course has been adopted with regard to the new rules. The work seems to have been very carefully revised since the second edition appeared, and, so far as we have been able to ascertain, no case of importance has been omitted. Although the book is by no means bulky, the index, one of the most important parts of a work of this nature, contains no less than 120 pages, and is divided into three parts to correspond with the three divisions of the subject-matter. The only improvement we can suggest is that in future editions the author should give all the references to a case, instead of one only, as practitioners may not be all possessed of the report cited.

Practical Electric Wiring for Lighting Installations. Illustrated with over 130 Original Drawings, Diagrams, and Plans. By CHARLES C. METCALFE, A.M.I.E.E., Electrical Engineer to the Education Committee, Manchester; Lecturer and Instructor in Practical Wiring at the Municipal School of Technology, Manchester. Harper and Bros., 45, Albemarle-street, W. Price, 5s. net.

This little book, as its title indicates, is a practical treatise on electric wiring, a subject which in the past has not always been given that serious attention which its importance warrants. The difference between good and bad wiring is the margin which separates perfect safety from constant danger. To borrow a phrase: "Bad workmanship cannot be redeemed by the use of good materials, but good workmanship can to a great extent redeem inferior material." Good workmanship and material should, therefore, be inseparable. Then, as the author points out, the use of higher pressures than formerly, with the correspondingly increased fire risks incurred by bad workmanship, make it imperative that the wireman of to-day should be a really skilled workman.

Digitized by Google

Further he must, especially if he desires to take charge of a job, possess a good general knowledge of practical wiring, have a more than nodding acquaintance with the internal arrangement of buildings and their construction, and be well up in the various rules issued by the fire insurance companies, the Institution of Electrical Engineers, and the supply companies in his immediate neighbourhood.

Unfortunately, in wiring installations the bad work that really matters is nearly always concealed from view. Wood casing and steel conduits are cloaks for weak spots. But it cannot be expected that wiremen will be infallible if their foremen are not themselves sufficiently alive to the importance of good workmanship. True, there are many wiring contractors who know their business and can be relied upon, but it is equally certain that this branch of electrical engineering still lends itself to the display of crass ignorance of the fundamental rules for safe work. The book which we have before us is well calculated to raise the general level of wiring work. It is suitable alike for foremen, wiremen, students, and for all those who wish to acquire a practical knowledge of wiring, jointing, and fitting for the installation of the electric light. The series of suggestions which it contains are based upon practical experience extending over some 17 years, being accompanied by plain instructions and diagrams for carrying them out. Chapters I. to IX. inclusive cover the whole range of work falling to the wireman's lot to execute, those on jointing and the insulation of joints being especially noteworthy. The remaining chapters should be of great use to architects and others practically concerned with electrical installations. They include a specification for a complete installation of electric lighting, and a description of the installation, with plans and sections of the building, etc. To conclude, "Practical Electric Wiring" is a book we can confidently recommend. It contains a mass of useful information which we do not remember having previously seen given in the same lucid manner.

National Engineering and Trade Lectures. Edited by BEN. H. MORGAN. Vol. III.: "British Progress in Gasworks Plant and Machinery," by C. E. Brackenbury, A.M.I.C.E., etc. Illustrated. London: Archibald Constable and Co., Limited. Price, 6s. net.

In these days when some local authorities are inclined to revert to gas as a street illuminant, and when gas interests are thus made jubilant, it behoves every responsible electrical engineer to keep himself thoroughly acquainted with the progress made in all that concerns gas. Electrical engineers must not imagine that their library is complete if it contains only works upon their own subject; it should contain whatever gives them information upon competing subjects, and in this book on gas they will find the latest information on the present position of gas production and the appliances used therein. The best and the most recent appliances for production this book describes and illustrates, but it does not deal to any extent, if at all, with that important matter—usage. It is not so much how produced as how used that interests electricals, and the most modern types of burners, their peculiarities and their efficiencies, is what the electrical engineer wants to know. Gas has gone ahead in its burning; electricity has not progressed quite so rapidly, and no doubt a glamour has been thrown around gas which acts upon the consumer to the advantage of gas.

The Use and Care of Chains for Lifting and Hauling. HENRY ADAMS, M.I.C.E., M.I.Mech.E. Second edition. 1s. 60, Queen Victoria-street.

This is the second edition of a paper which was first read at a meeting of the Civil and Mechanical Engineering Society in April, 1887. The author is an expert on chain work, and when the Home Office recently prepared a series of draft regulations for docks and wharves much opposition was aroused, and he was called in to give the authorities the benefit of his long practical experience in connection with dock machinery and cranes, with the result that the regulations finally issued were considerably modified, and the dock owners relieved from what would have been onerous restrictions upon the carrying out of their work, particularly as regarded the testing of their chains and machinery.

New Electrical Handbooks.

ALTERNATING CURRENTS:
Their Theory, Generation, and Transformation.

By ALFRED HAY, D.Sc., M.I.E.E.

Demy 8vo 178 Illustrations. 307 pages. Price 6s. net; post free 6s. 4d.

CONTENTS—Theory of Single-Phase and Polyphase Currents—Theory of the Wattmeter—Measuring Instruments—Alternators, Transformers, and Induction Motors—Synchronous Motors and Parallel Running—Regulation of Alternators and Transformers—Testing of Alternators and Transformers—Theory of Induction Motors and Circle Diagram—Testing of Induction Motors—Induction Generators and Speed Control of Induction Motors—Rotary Converters—Compensated Induction Motors and Compounded Alternators—Single-Phase Commutator Motors.

PRACTICAL ELECTRIC WIRING
for Lighting Installations.

By CHARLES C. METCALFE, A.M.I.E.E.,
Electrical Engineer to the Education Committee, Manchester.

Demy 8vo. With over 130 Illustrations from Original Drawings and Photographs. 5s. net; post free 5s. 4d.

Special Chapters are devoted to:—Fitting and General Arrangement—Tools—Accessories—Systems—Wires and Cables—Joints—Flexible Conductors—Insulation of Joints—Plans and Schedule—Specification—Installation.

ELECTRIC TRACTION.

By ROBERT H. SMITH,
Assoc.M.I.C.E.; M.I.Mech.E.; M.I.E.E.; M.I. and St.I.; Whit. Schol.

Demy 8vo. 465 pp. 347 Illustrations. 9s. net; post free 9s. 6d.

An up-to-date and authoritative work upon Electric Traction in all its aspects. The dynamic and constructional principles are dealt with in detail, and are mainly based upon examples already existing or actually under construction. The author emphasises the consideration of economic conditions and commercial results as aspects which call for more study than they generally receive, and supplies copious data from authoritative sources.

ELECTRICAL ENGINEERING.

By E. ROSENBERG.
Translated by W. W. HALDANE GEE, A.M.I.E.E., of the Manchester School of Technology, and CARL KINZBRUNNER, A.M.I.E.E.

Demy 8vo. Profusely Illustrated. 6s.

A comprehensive Text-book for all who desire a knowledge of the chief principles of the subject. It comprises, besides the fundamental phenomena of the electric current, dynamos and motors for continuous, alternating, and three-phase current, accumulators and their apparatus, measuring instruments, electric lighting, alternating-current engineering, and polyphase work.

STARTERS AND REGULATORS
for Electric Motors and Generators:
Theory, Construction & Connection.

By RUDOLF KRAUSE.
Translated by C. KINZBRUNNER, A.M.I.E.E., and N. WEST, A.I.E.E., of the Manchester School of Technology.

Demy 8vo. Profusely Illus. 4s. 6d. net; 4s. 10d. post free.

Special Chapters are devoted to:—The Conduction of Electric Currents—Circuit Breakers and Circuit Breaking—Theory of Starters—Mechanical Construction of Starters—Calculation of Regulating Resistances for Generators and Motors—Construction and Connections of Regulators for Generators and Motors.

TESTING OF CONTINUOUS-CURRENT
Machines in Laboratories and Test-Rooms.

By C. KINZBRUNNER, A.M.I.E.E.

Demy 8vo. Profusely Illus. Price 6s. net; 6s. 4d. post free.

Special Chapters are devoted to:—Resistance Measurement—Measure of Temperatures—Insulation Measurements—Measurement of Speed—No-Load Characteristics—Load Characteristics—Magnetic Measurements—Efficiency—Separation of Losses—Practical Testing of Continuous-Current Machines.

THE DISEASES OF ELECTRIC MACHINERY:
Their Symptoms, Causes, and Remedy.

By C. KINZBRUNNER, A.M.I.E.E.

Limp Cloth. Price 1s. 6d. net; 1s. 8d. post free.

No advanced knowledge of Electric Machines is assumed, and Special Chapters are devoted to:—Sparking—Excessive Heating—Dynamo Fails to Generate—Motor Fails to Start—Speed of Motor too High or too Low—Noise—Faults with Starters and Regulators—Alternating-Current Generators with Rotating Armatures—Alternators with Rotating Field—Single and Multiphase Induction Motors—The Installation, Care, and Maintenance of Electric Machines.

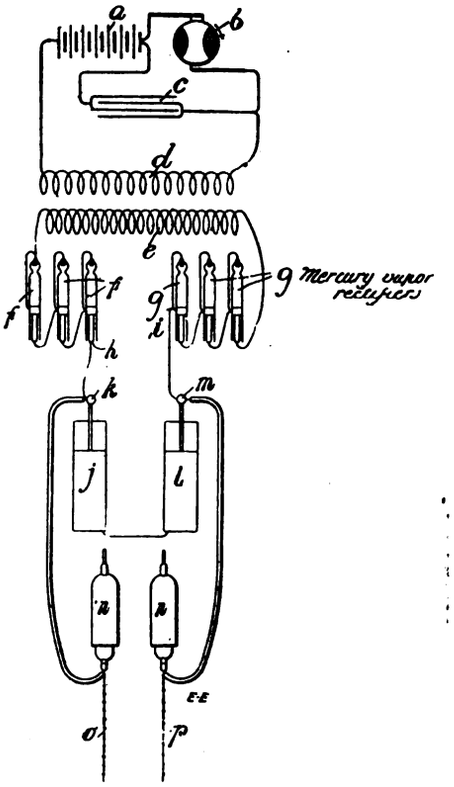
Charing Cross Disaster.—The collapse of the glass roof which spans the southern portion of Charing Cross Station, without the slightest warning, cannot but evoke expressions of sympathy with the sufferers and the directors and officials of the South-Eastern Railway Company. It is impossible to say at present whether the accident was due to subsidence or to the breaking of a stay-rod (which are the most probable theories), but technical investigations and a Board of Trade examination will locate the cause. At present men are engaged in clearing away the *débris* and strengthening the remaining portion of the roof. These operations have been considerably expedited by the excellent work performed by the Electrical Engineers Volunteer Corps, the value of whose services is worthy of the highest appreciation. At 6.30 p.m. on Tuesday evening a message was received at headquarters, where some of the men had gathered for drill, asking for assistance. Colonel Crompton immediately gave orders for the dispatch of men and apparatus to the scene of the disaster. Fortunately, Captain J. H. S. Phillips (machinery officer) was present at the time, and under his direction two searchlights with all the gear were got ready and transferred from the drill hall to Charing Cross. Primitive resistances, consisting of a combination of old iron wire and wheel trucks, were fitted up by the men, and the projectors mounted on two horse-boxes covered with tarred canvas; current was obtained from the Charing Cross Company's mains, and within two hours after having received the first call the projectors were in working order, lighting up the operations on the roof. The complete transfer of the gear and its erection at the station was entirely effected by the officers and men of the corps in so remarkably short a time, and this notwithstanding the fact that some little delay was occasioned in connecting the supply and adapting the 80-volt gear of the corps for the 200-volt current of the supply company's mains, which necessitated the bringing of a great deal of additional gear. Until the arrival of the Electrical Engineers work on the roof was at a standstill, as it was impossible to use torches on that class of work. The men consequently have been employed with their searchlights every night this week from dusk till 8 a.m. on the following morning, and they are ready to give their services for any length of time. Captain J. H. S. Phillips has been in attendance during practically the whole of the time since the installation of the apparatus, and under the directions of this capable officer, ably supported by Captain W. Bunn and Lieutenant E. G. Sheppard, the men have bravely carried on their valuable work. This is the first occasion on which volunteers have been called upon to do work of an indispensable character under such circumstances as the present, and the feat of the Electrical Engineers serves to show that, although their work is carried on quietly and unobtrusively, it is of the utmost value to the country.

Dispersement of Fog.—At a time of the year when the atmosphere is charged with aqueous vapours and impure emanations, and when the City is for the greater part wrapped in dense fog, it is singularly appropriate to turn attention to devices which have been introduced with the object of dispelling fog. Experiments with high-potential discharges for fog condensation were formerly carried on by the aid of Voss or Wimshurst electrostatic machines, but the apparatus was found too delicate for use on an extensive scale. Sir Oliver Lodge has given close attention to the subject for a great number of years, and his studies have culminated in the invention of a high-potential discharger for dispelling fog, for which a patent has just been granted in the United States. The present contrivance, which is described in the *Western Electrician*, is such that the current from a dynamo, either continuous or alternating, is so transformed and treated as to give a practically continuous high-potential discharge in one direction only. Further, the invention consists in combining high-potential rectifiers in such a way that, instead of reverse pulses being suppressed, they are redressed to form positive and negative discharging streams required for deposit purposes. In the accompanying diagram there is a



battery, *a*, in circuit with an intermitter, *b*, and the primary of a large Ruhmkorff induction coil. A condenser may be placed in parallel with the intermitter. The secondary of the Ruhmkorff coil is connected through two series of high-potential mercury vapour rectifiers to the terminals, *k*, *m*, of the insulated coatings of Leyden jars whose outer coatings, *j*, *l*, are in electrical connection. To the terminals are also attached the leads or discharging wires, which are supported by insulators, *n*. In the operation of the apparatus the current generated in the battery or dynamo is interrupted by the intermitter, and induces intermittent pulses of violently high potential in the secondary coil of the Ruhmkorff coil. These pulses are transmitted through the rectifiers—positive pulses through the series *f* and negative pulses through the series *g*—to the insulated coats of the two Leyden jars. The object of each series of rectifiers is to transmit a current easily in one direction and to strongly oppose a passage of current in the opposite direction. By this means the intermittent supply from the induction coil is enabled to maintain the jars steadily charged. The higher the potential desired the more numerous are the rectifiers required in each series. It has been found that six in each series is a convenient number to use where it is required to keep up a practically continuous discharge between the dischargers. By suitable arrangement of the discharging means, the invention can be applied to various purposes in which continuous high-potential discharge in one direction is required, such as, for example, where it is desired to utilise the high-potential discharge in causing the deposit of lead fumes in the manufacture of white lead by furnace processes, and in the depositing of valuable factory dust by means of a combination of the electrical discharge apparatus and a centrifugal settling chamber.

BELFAST ELECTRIC TRAMWAYS.

The first tramways in Belfast were laid under the Act of 1872 by the Belfast Street Tramways Company, and were altered and extended under subsequent Acts and orders until the lines owned and worked by the company consisted of 35 route miles. From the commencement until the present time the tramways have been worked by horses, but in February of this year the Corporation proceeded to relay, extend, and electrify the tramways, having acquired the undertaking from the company under an Act passed during the session of 1904. The amount paid by the Corporation to the Belfast Street Tramways Company for their undertaking was settled by arbitration, and the amount awarded by the arbitrator, Mr. L. L. Macassey, LL.D., C.E., including the value of three years' unexpired lease, compensation to officers, and £60,000 debentures (to be paid off by the Corporation), was £364,448.

In July, 1904, Mr. Henry A. Cutler, M.I.C.E., the city surveyor, and Mr. V. A. H. M'Cowen, M.I.E.E., the city electrical engineer, reported to the newly-formed Tramways Committee of the Corporation on the various systems of electric traction, in which they set forth the merits and cost of the different systems, having regard to local conditions, and strongly recommended the adoption of the overhead trolley system. The committee adopted the report of their engineers, and instructed Mr. Cutler to prepare drawings, specification, and quantities for the permanent way and the buildings required for the generating plant; Mr. M'Cowen to prepare a scheme for the electrical operation of the system, including specifications for the generating plant, cables, and overhead equipment; and Mr. Nance, who had for many years managed the horse tramway system under the old company, and had been appointed manager for the Corporation, to prepare a specification for new rolling-stock and to make the necessary alterations and additions to the car-sheds and depôts, so as to make them available for the new undertaking. Mr. Nance has supervised the construction and equipment of the cars and carried out the whole of the work in connection with the depôts by administration, and what drawings were necessary were prepared by the city surveyor. After the specifications had been submitted to Messrs. Lacey, Sillar, and Leigh for expert advice, tenders were invited for the work of reconstruction and electrification of the tramways, excluding the buildings, in six different sections, which led to a very keen competition,

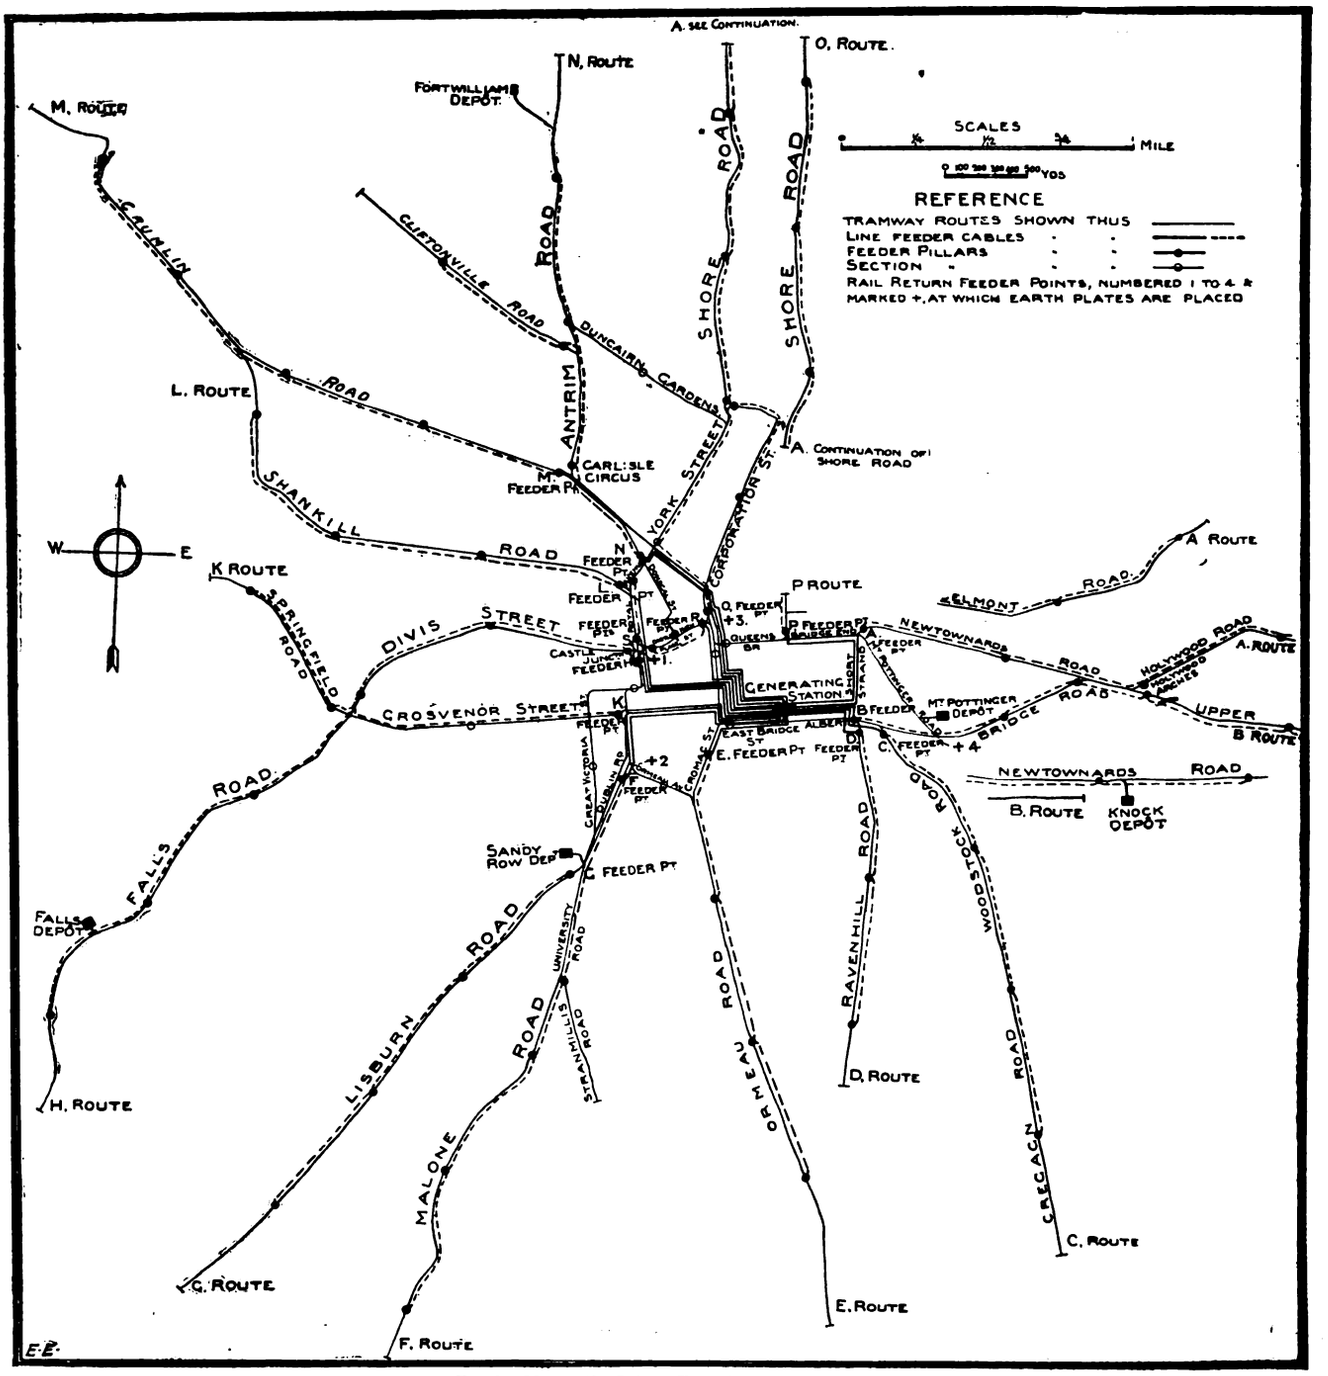

FIG. 1.—Map of the Belfast Electric Tramways.

Digitized by Google

and eventually the tender of Messrs. J. G. White and Co., of London, for the whole of the six sections, amounting to £543,404, was accepted.

Permanent Way.

The reconstruction of the permanent way was commenced last February under the superintendence of Mr. E. S. Pinkerton, A.M.I.C.E., who acted as resident engineer, and Mr. F. Lewis, who acted as clerk of works. All the routes were laid as double line to a gauge of 4ft. 9in., and the work now completed consists of about 80 miles measured as single track. Sixteen single-track miles of the tramways were laid only five years ago, and as this portion of the work was in fair condition, the renewal of the special work, bonding, and general repairs was the only work necessary in connection with them. British standard sections were adopted for the rails and fishplates used in the new track, No. 4 section, weighing 105lb. to the lineal yard, being used on the straight and flat curves, and No. 4c section, weighing 111lb. to the lineal yard, on curves of 66ft. radius and under. The rails were manufactured to the British standard specification by the North-Eastern Steel Company, Middlesbrough. The rails (Figs. 2 and 3) are anchored at the joints with Cooper anchors, consisting of 2ft. lengths of rail inverted and riveted to the under flange of the rails with 12 rivets at each joint. Attached to the rail between the joints are intermediate anchors spaced about 11ft. apart, consisting of sections of steel joists 8in. long, riveted

MR. HENRY A. CUTLER, A.M.I.C.E., CITY SURVEYOR, BELFAST.

transversely to the under flange with four rivets to each anchor. The tiebars, which are of mild steel, 2in. by ¼in., are Bayliss's patent, with lock nuts at both ends. The joint bonding has been executed with 0000 B. & S. gauge copper bonds of the protected type, two bonds being fitted to each joint under the fishplates. Solid crown cross bonds have been put in at 40-yard intervals in the tracks, and 80-yard intervals between the tracks.

The whole of the special work (Figs. 4 and 4A) was manufactured and supplied by the Lorain Steel Company. The points to junctions are made to a radius of 150ft, and are armoured with manganese steel insert pieces. The crossings are of iron-bound type with steel-armoured centres. The whole of the special work was manufactured and fitted together at the company's works in America, and delivered on the ground ready for laying. The care with which the work had been designed and manufactured enabled it to be put together on the site without the slightest trouble. Owing to the close spacing of the rail anchors, it was possible for some modifications of the usual method of tracklaying to be made and do away with the necessity for removing temporary rail packings after the concrete had been put in. The method adopted was as follows: When the necessary excavation had been completed, the rails were put in position, the fishplates, anchors, tiebars, and bonds fitted, and the rails packed temporarily in the usual way, leaving sufficient space underneath for the proper thickness of the concrete bed; then, when the platelaying had been completed, plastic concrete packing was put under the anchors and left for about 24 hours to set. The concrete bed was then put in in the usual way and packed tight under the rails while in a plastic state, the temporary packing being drawn in front of the concrete gang, leaving the track supported on the permanent anchor packing instead of relying upon the temporary packings, which usually have to be withdrawn after the concreting has been completed. The concrete bed (Fig. 5) under the rails consists of broken stone, gravel, and cement, mixed in the proportions of 6 of the aggregate to 1 of cement. Its normal thickness was 7in., and the upper surface was finished 1in. above the rail bed. Where the foundation was considered unreliable the thickness of the concrete was increased, in some places to as much as 12in. The paving has been executed with granite setts

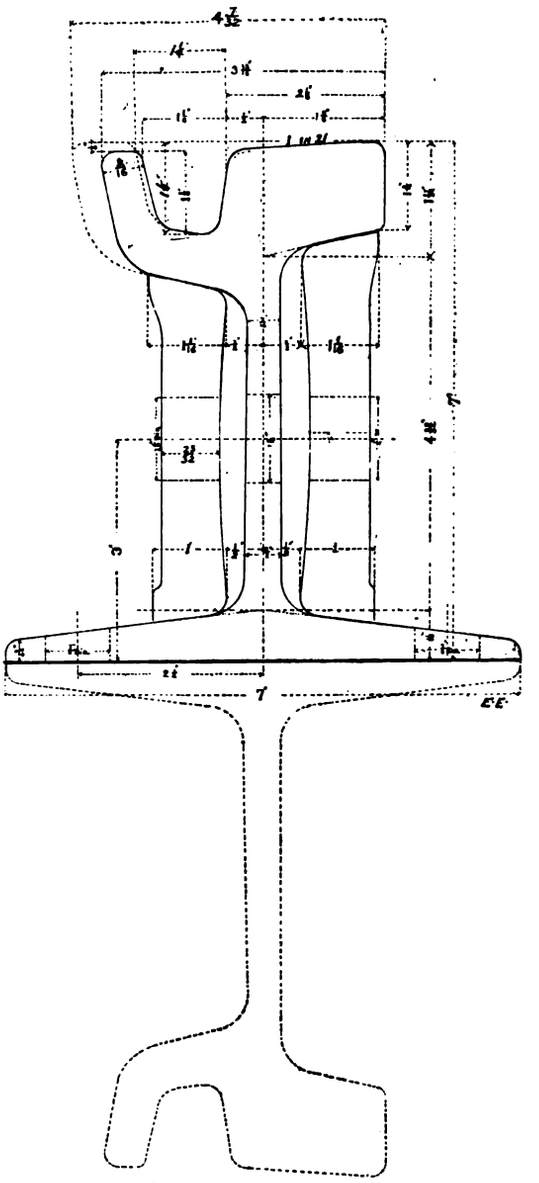

Fig. 2.—Section of the Rails used at Belfast.

5in. to 5½in. deep and 3in. to 4in. wide. The setts were laid on a dry compo bed mixed in the proportions of 4 of sand to 1 of cement, which was thoroughly wetted after the paving had been laid, and the joints were then grouted up with 3 to 1 compo, and back washed after the setts had been rammed. In the bulk of the work the rails were not parged, as the grouting was found to properly fill the space between the setts and the web of the rail, and to make a more satisfactory job. In some places, where it was necessary to turn the traffic on the road immediately after completion, such as at road crossings, the rails were parged, the setts bedded on sand, the joints racked up with chippings and grouted with pitch and creosote oil.

The work in connection with the permanent way was started in February, and has been completed in a record-breaking time, which speaks well for the organisation and

Digitized by Google

energy of the staff of the contractors. In carrying out the work numerous alterations had to be made to sewers, gas, water, and other mains, and in two places roads had to be lowered to provide the proper headway under bridges.

Power Station.

The contract for the new power station necessary for the generating plant for the tramway undertaking was let to Messrs. M'Laughlin and Harvey, of Belfast, whose tender of £19,690 was accepted by the Council. The site of the building (Fig. 6) adjoins the electric light station and is very centrally situated close to the bank of the River Lagan, which is navigable for barges to the site of the works, and will provide an unfailing supply of water for condensing. The building was designed by Mr. Cutler in such a way as to make it possible to instal the plant during the erection of the building. The work was commenced in April last, and owing to the soft nature of the ground some 1,750 piles had to be driven through 30ft. of river mud down to the rock. The foundations on top of the piles are formed with cement concrete, in which is embedded a steel grillwork made of old tramrails. The framework of the building is made of steel, and the roof and floors were erected before the brickwork was commenced, which enabled the coal bunkers, boilers, and engines to be installed during the time the building was being erected. This arrangement afforded the only possible way of having power available for running the cars in such a short time as was allotted for the completion of the work. As a result of the preparation made in designing the structure, the engines are now running and current being generated although the building is not completed. The new building is designed to harmonise with the existing electric light station. It has a frontage of 180ft. to East Bridge-street and 138ft. to the Lagan Bank-road. It is faced with red brick with stone dressings. The floors in the basement of the building are formed of concrete rendered with cement, and the stoking floor and switch gallery floors

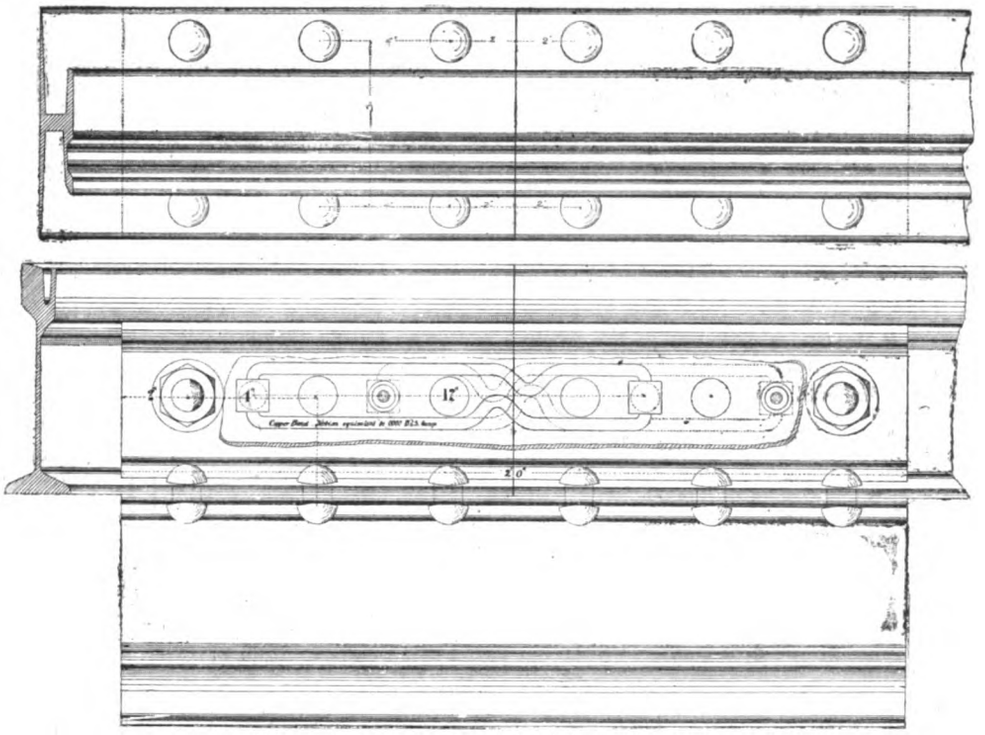

Fig. 3.—Details of Rail Joint.

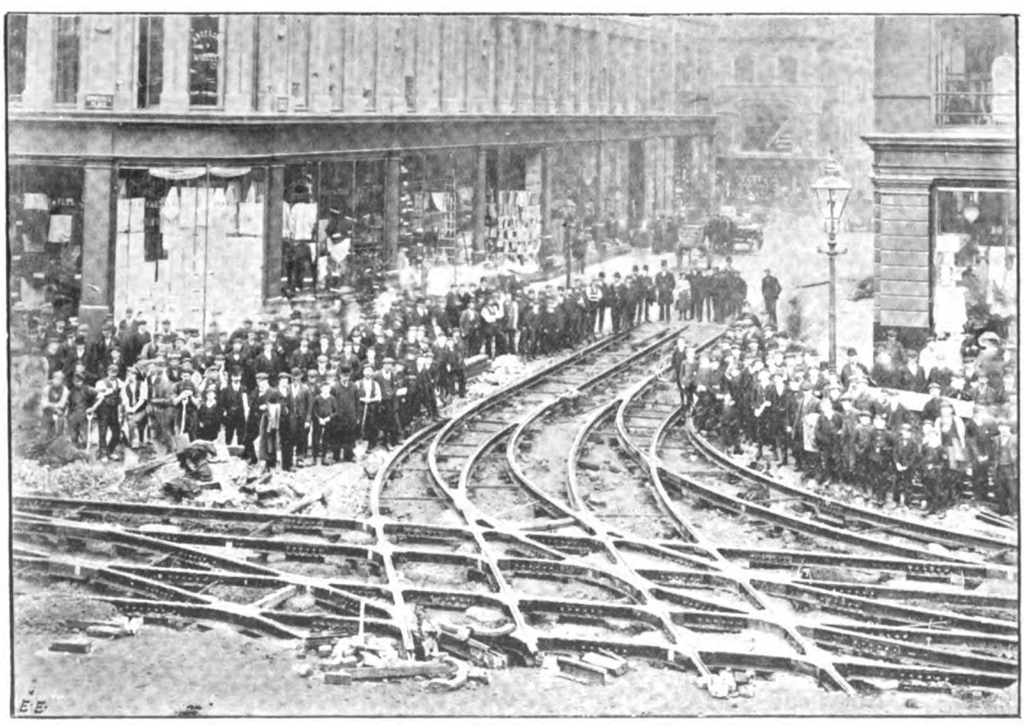

Fig. 4.—Special Work at Belfast.

Digitized by Google

are formed with concrete on steel joists. The stoking floor is finished with Staffordshire blue paving bricks, the switch-gallery floors with vitreous glass mosaic, and the floor of the engine-room with encaustic tiling. The skylights for lighting the engine-room and boiler-houses are glazed with Helliwell's patent glazing, and the walls of the engine-house and switch galleries are faced with glazed tiles. The great care and energy which have been displayed by Messrs. M'Laughlin and Harvey in carrying out their contract have been no small factors in the expeditious completion of the work, and they are to be highly commended for the facilities they have afforded other contractors working in the building.

Pump-House.

The contract for the pump-house, in which the condensing water pumps are erected, was let to Messrs. Courtney and Co., of Belfast, whose tender amounted to £6,281. The pump-house is situated on the bank of the River Lagan, and a cofferdam along the river front and two sides had to be constructed before the work was commenced. The pump-house is 68ft. long and 16ft. 6in. wide, and is built of red brick with stone dressings. The pump wells are built in concrete faced with blue brick, and the openings to the river are protected with movable screens to prevent foreign matter entering the wells. The pumps are carried over the pump wells on steel joists, and the floor is constructed of concrete and paved with tiles. Considering the risk natural to the work, and the conditions under which it had to be executed, the contractors are to be complimented upon the expeditious manner in which they have carried out their contract. In designing and supervising the construction of the power-house and pump-house, Mr. Cutler was very ably assisted by his chief architectural assistant, Mr. J. C. M. Browne, C.E., and by Messrs. J. Trotter and F. Byers, who acted as clerks of work.

Generating Station.

The generating station (Figs. 7 and 8) forms an extension of the central electricity works which was erected in 1898, this site at the time being recommended by Mr. M'Cowen as a suitable point for distributing energy for the city's requirements both for lighting and traction purposes, and all the plant installed has been arranged for both lighting and traction supply, the generators being provided with compound windings for tramway supply at 550 volts, the lighting pressure being 440 to 500 volts on the outers of the three-wire system. The plant in the original works consists of high-speed steam dynamos having a total capacity of 3,400 kw.; the engines throughout are of Belliss and Morcom's make, the dynamos being by Mather and Platt, Parker, and Johnson and Phillips. The boiler-house plant consists of six Lancashire and six water-tube boilers, together with economisers and steam and electrically driven feed pumps. The condensing plant is of the Wheeler combined type, with steam-driven horizontal air and circulating pumps placed below the condenser, cooling water being obtained from Wheeler and Klein cooling towers. Owing to the large developments in

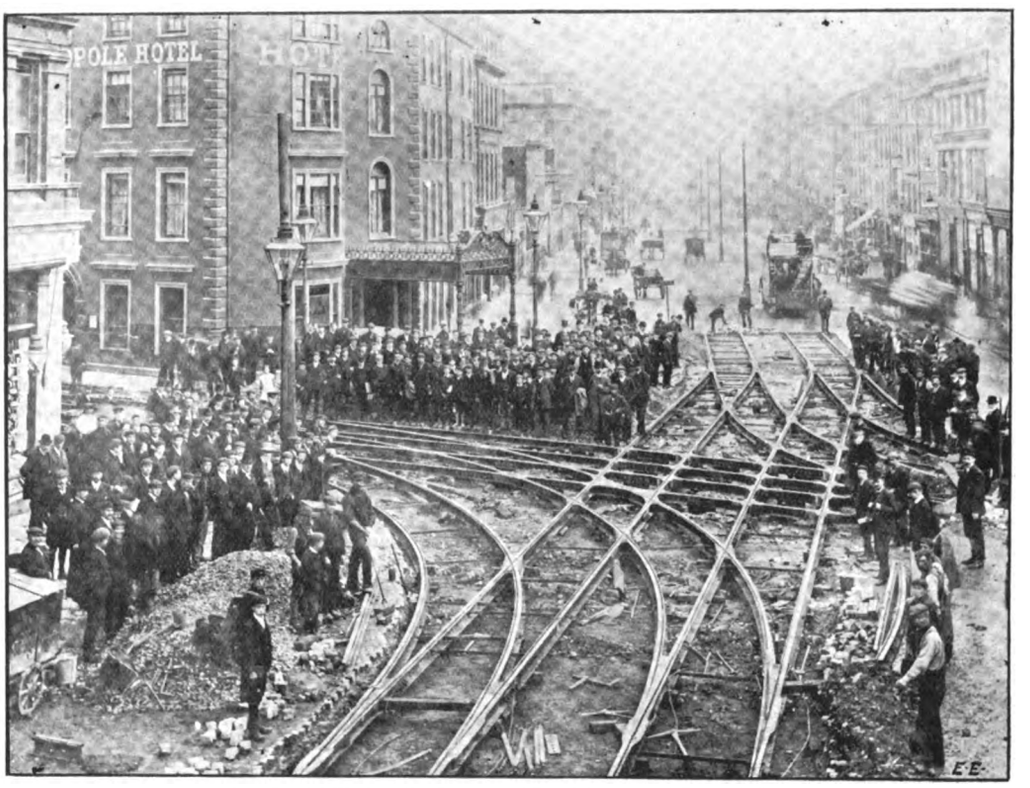

Fig. 4A.—Special Work at the Junction of Royal Avenue and Donegal Street.

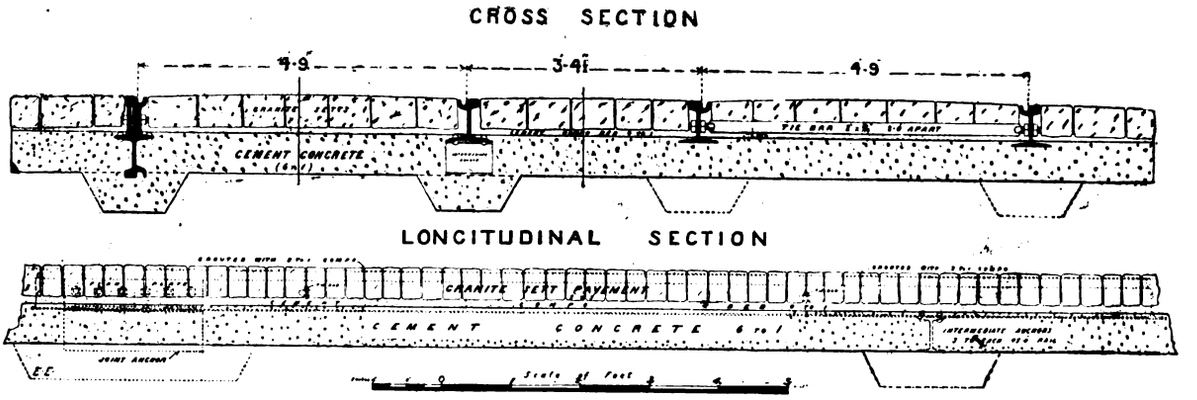

Fig. 5.—Section of the Belfast Track.

Digitized by Google

the lighting and power demand, it has been found necessary to extend the building and instal further plant. Provision, however, is made for running three of the large lighting generators on the tramway system if required. The power station is situated close to the River Lagan, and the position is convenient for obtaining condensing water and delivery of coal by barges.

Coal-Handling Plant.

Fig. 8 shows the general arrangement of the coal-conveying scheme. The coal is brought alongside the quay in

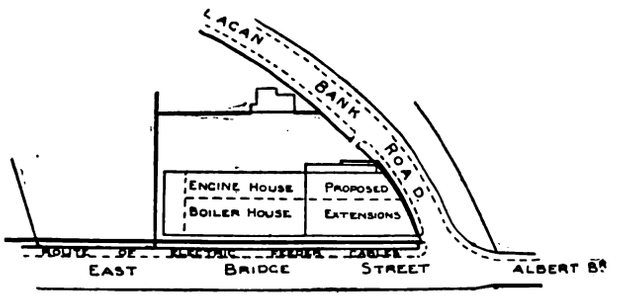

Fig. 6.—Block Plan of Site.

barges, and there discharged by means of a grab operated by an electric locomotive crane, which deposits it into the hopper of an "Ingrey" automatic weighing and recording machine, which discharges it into a receiving hopper underneath. From this hopper the coal passes by means of a shoot, with regulating valves, into an automatic filler, which fills the buckets of the conveyor without spilling. The coal is then elevated vertically (by means of the conveyor, which is of the continuous gravity bucket type) to a suitable height to cross the public road through a covered way into the building, above the ashes can be discharged at suitable times by means of a shoot with regulating valves into either carts or barges underneath. It will thus be seen that the conveyor can be employed for both the delivery of the coal and the removing of ashes at the same time. The conveyor is of the endless-chain pattern, with buckets of the gravity type, and is capable of handling from 40 to 50 tons of coal per hour with a speed of the conveyor chain of 40ft. to 50ft. per minute. The conveyor chain is driven by a special driver with pawls which engage the link studs in each part of the chain on both sides of the bucket. This driver is direct coupled through suitable spur and pinion gear to a 9-h.p. motor of the enclosed type. A movable filler is also provided in the basement for facilitating the trimming of the coal from one bunker to another, and in connection with the removal of the ashes. The "Ingrey" patent automatic weighing and recording machine registers in tons and decimals each charge of coal as it is delivered by the grab, and the total quantity of coal delivered at any time can be ascertained by reading the index. The accuracy is guaranteed to within ½ of 1 per cent

Steam-Raising Plant and Auxiliaries.

Boilers.—The lay-out of the boiler-house is shown in Fig. 7, the arrangement being a single row of boilers placed in batteries of two. Each boiler is provided with its own economiser immediately at the back, and this opens direct into the main flue. By this means the economisers receive the full heat value of the waste gases before cooling due to radiation or leakage can take place. Four Babcock and Wilcox water-tube boilers are erected under this extension. Each boiler is composed of 20 sections of 13 tubes, 4in. diameter and 18ft. long, connected at the ends by staggered headers to the steam and water drums, which are each 25ft. long and 54in. diameter. Each boiler has a heating surface of 5,764 square feet and a grate area of

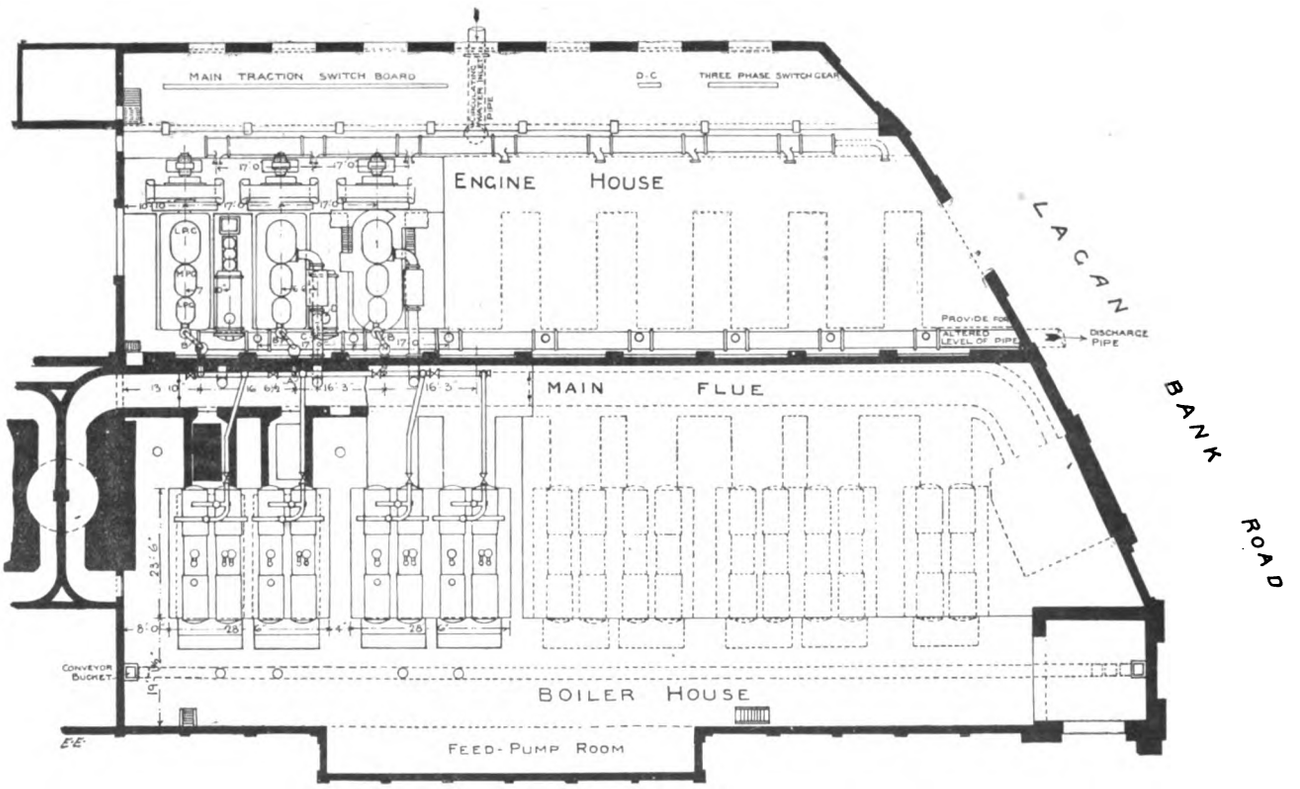

Fig. 7.—Generating Station Extensions required to meet the tramway load.

level of the overhead bunkers, each bunker being provided with a pair of suitable dumping cams, so that the coal can be deposited where required. The overhead bunkers are of steel construction throughout, and are situated over the boiler stoking floor, and have a capacity of 1,000 tons. The conveyor runs above the bunkers the whole length of the boiler-house, and descending at the end wall passes through the basement, where it is again employed for removing the ashes from below the boilers. It then re-ascends at the other end of the boiler-house, and re-crosses the road through the covered way, and deposits the ashes in the ash hopper on the riverside. From this hopper the 100 square feet, and is capable of evaporating from 20,000lb. to 25,000lb. of water per hour from and at 212deg. F. Each boiler is fitted with a Babcock and Wilcox patent superheater having 900 square feet of heating surface, and capable of imparting a superheat of 150deg. F. to the steam produced by the boiler. Each boiler is provided with a double 5ft. by 10ft. Babcock and Wilcox patent mechanical chain-grate stoker. The grate of same consists of an endless chain of short cast-iron bars linked together and actuated by passing over drums at the front and rear, the front drum being revolved by a worm-wheel; gearing is also provided to enable the whole stoker to be brought

Digitized by Google

out clear of the boiler. These stokers are of the coking type; the coal is fed over the whole width of the grate, the thickness of the layer of coal being regulated by the vertically sliding fire-doors. The speed of the travel of the grate can also be varied between wide limits, so as to meet any variable demand for steam on the boiler. The ashes and clinkers are dropped over the end of the grate into a clinker pit in the basement, from which they are removed by the conveying plant. The whole of the stokers are driven by a line shaft placed beneath the stoking floor, and connected by clutch gear to duplicate electric motors geared by means of worm reduction gear. The economisers are of Green's well-known make, 128 pipes to each boiler; these are of the latest construction and design, constructed for high-pressure working. The scraper gear of each economiser is driven through a worm gearing by means of an electric motor, and very complete provision is made for removing soot from both the boilers, economisers, and flue and depositing same in the basement, where it can be removed by means of the conveying plant.

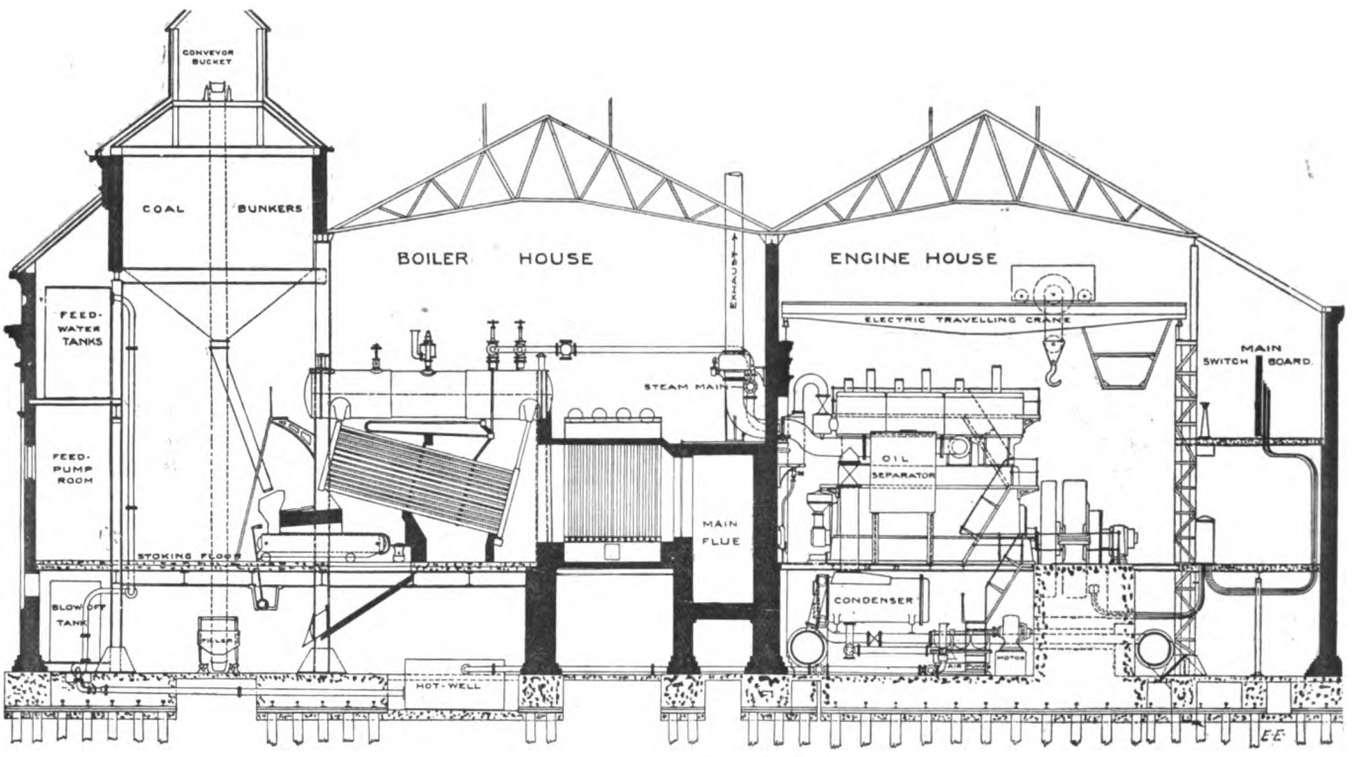

FIG. 8.—Section of the Generating Station.

Pipe Work, Feed Pumps, etc.—The arrangement of steam-pipe work is extremely simple, as can be seen in Fig. 8. Each boiler, economiser, and steam dynamo forming a unit, and are connected by means of an 8in. steam-pipe, the 10in. main steam-pipe in the boiler-house simply acts as an equaliser between the various units. Each unit, therefore, can be separated from its neighbour by means of a valve on the main steam-pipe placed between the unit branches, so that each unit can be run quite independently from each other if necessary. The pipes are arranged to obviate the undesirable necessity of steam-traps, each section of pipe work draining to its own engine separator, which is protected by a trap. The steam-pipes are of weldless mild steel having a tensile strength of 24lb. to 27lb. per square inch with an elongation of 20 per cent. in a length of 6in., no cast iron or copper being employed. All pipes up to 6in. diameter have wrought-steel flanges screwed on, and the pipe afterwards carefully expanded into the flanges; for pipes above 6in. in diameter the flanges are riveted on. The branch connections are formed by means of mild-steel nozzles riveted to the pipe. The valves on the boiler are arranged so that either "raw" or "superheated" steam can be taken. A duplicate system of feed is provided throughout; supplies are taken from two of the Water Commissioners' mains, and are connected to the overhead storage tanks and the hot-feed tank through

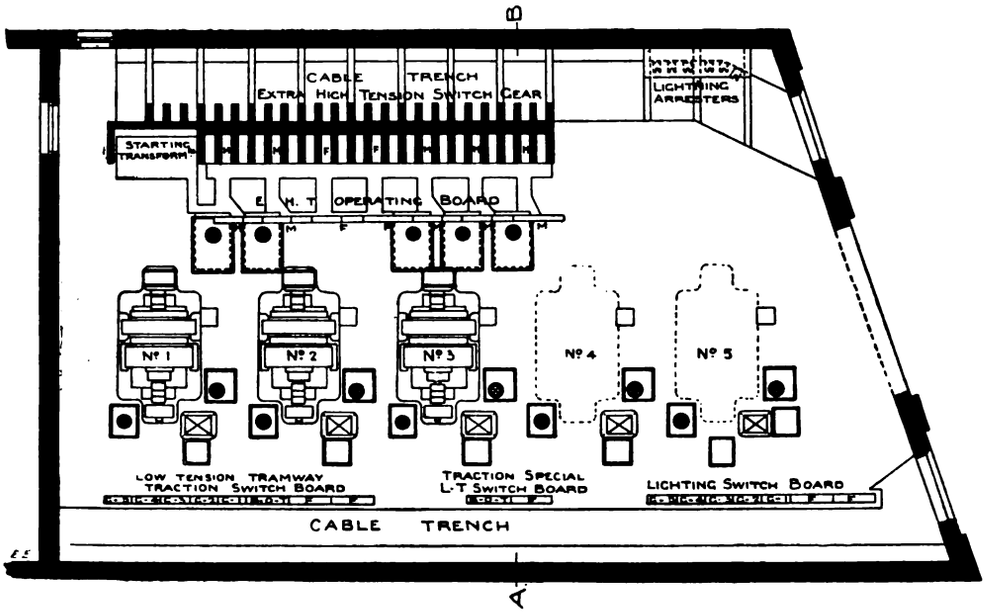

FIG. 9.—Plan of the Fortwilliam Sub-Station.

Digitized by Google

ball equilibrium float valves. Duplicate sections are connected from these tanks to the pumps, and duplicate deliveries are run between the pumps and the boilers, one of the deliveries being connected through a 6in. Railton and Campbell pressure feed-water filter, a 6in. Kennedy water-meter, and an auxiliary heater, which takes the exhaust from the steam-pumps to the economiser and thence to the

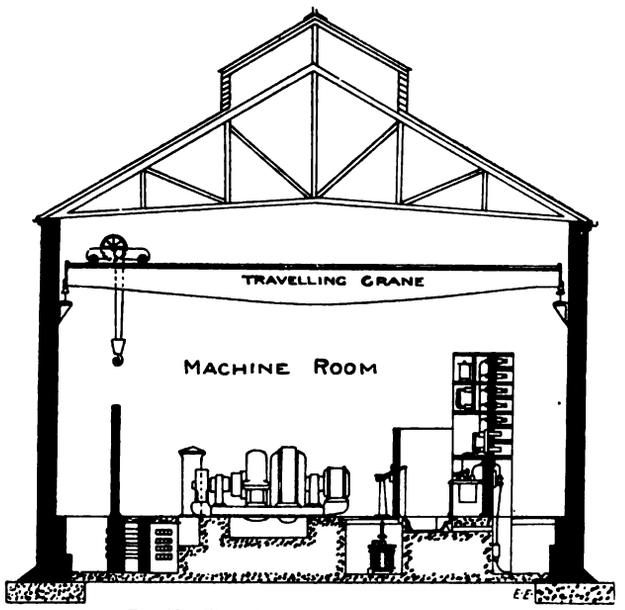

FIG. 10.—Elevation of the Fortwilliam Depot

boilers; the other delivery, which is only used in case of emergency, being connected direct from the feed pumps to the boilers. The feed pumps consist of one Hall compound vertical steam-pump capable of delivering to the boilers 8,000 gallons of water per hour with and against 170lb. to 200lb. pressure per square inch, at a speed of 12 double strokes per minute; two Hayward-Tyler "Sinclair's" electrically-driven variable-stroke pumps, each capable of delivering to the boilers 8,000 gallons of water per hour against the boiler pressure. The variable-stroke feed pump has several advantages that are not possessed by pumps controlled by any other method. Among these may be cited the following: The pump can always be started at "no stroke," thus avoiding heavy starting current. No variation in speed is required. No electrical complications are introduced, and variations in delivery are made while the pump is running without interrupting the feed supply, and by the simple movement of a small hand lever, which is held in position until the required rate of delivery is obtained. An infinite number of rates of working is provided, as the pump may be set for any capacity between zero and the full output. When the pump has been set to work at any particular output, and the voltage of the supply remains constant, the rate of discharge will also remain constant. After the pump is started no further manipulation of electrical gear is necessary, thus enabling the pump to be left safely in the hands of the ordinary boiler attendants. In order to enable the attendant to regulate the pump to the requirements of the boilers, an automatic indicator is fitted to the end of the shaft, which shows either the stroke in inches or the equivalent discharge in gallons per hour. The following are the guaranteed figures for the feed pumps: steam pump, 110lb. of water pumped per pound of steam; electric pumps, 3,600lb. of water pumped per Board of Trade unit. The valves employed throughout are of Hopkinson's own make for a working pressure of 200lb. per square inch with outside screw spindles. The boilers and all steam and feed pipes are covered with non-conducting material to a thickness of 2½in, the pipes in the engine-room being further finished with a covering of planished steel. The boiler-house is provided with an "Ados" flue-gas recorder and a steam-pressure recorder.

ENGINE HOUSE PLANT.

The generating plant erected under this extension consists of three 1,000-kw. direct-current steam dynamos. The engines are of the vertical inverted three-crank triple-expansion enclosed type with forced lubrication, by Messrs. Combe-Barbour, Limited, and constructed to run at a speed of 180 r.p.m. with steam pressure of 170lb. per square inch and 150deg. F. of superheat, the cylinder dimensions being 22in., 33in., and 50in. by 24in. stroke. The steam consumption at full load condensing under the above conditions of steam pressure and temperature, and with

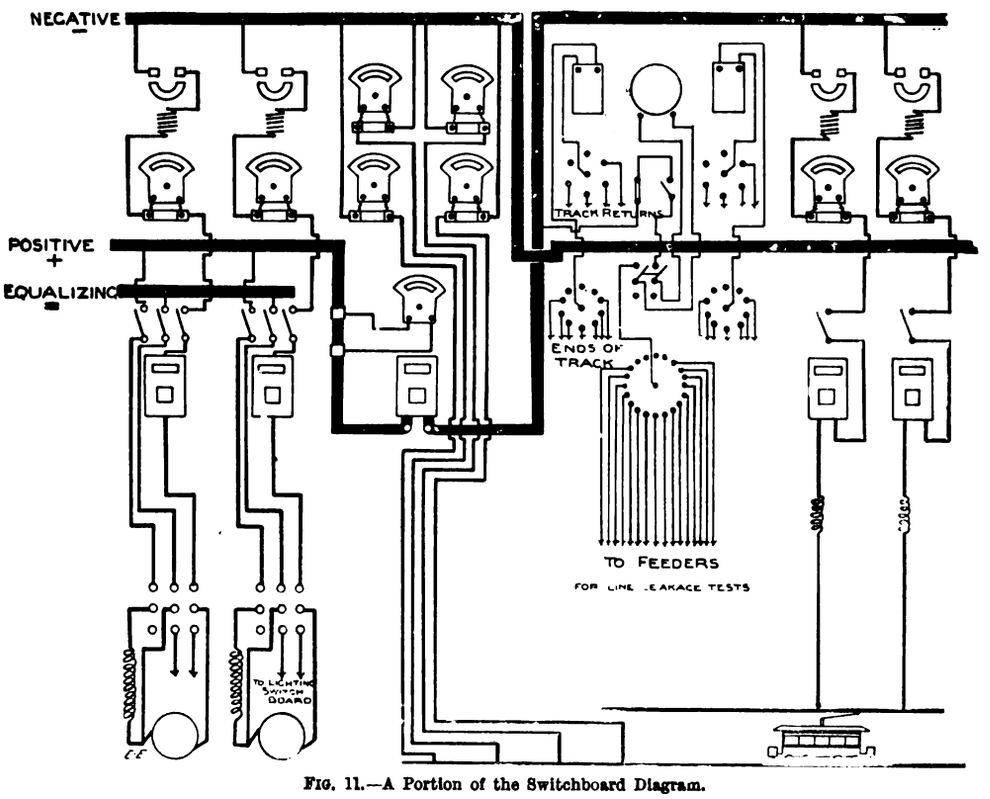

FIG. 11.—A Portion of the Switchboard Diagram.

25in. of vacuum, is guaranteed at 16¾lb. per kilowatt-hour, subject to additions or deductions of £250 per engine for every pound of steam per kilowatt-hour below or above that figure. The generators are of the Westinghouse 16-pole type 1,000-kw. sets, wound for a constant voltage of 550 when connected as compound for traction purposes and 450 to 500 when connected as shunt

Digitized by Google

for lighting purposes. These sets are capable of standing 25 per cent. overload for short periods, and 50 per cent. overload momentary.

Condensing Plant.

The condensing plant is of the counter-current surface type, with three-throw Edwards air-pumps, manufactured by Messrs. Mirrlees-Watson Company. The circulating water is obtained from the river by means of electrically-driven centrifugal pumps, arranged in a pump-house on the river bank. Three Gwynne electrically-driven centrifugal pumps are at present erected—two 12in. and one 15in.—and provision is made for the erection of two more when required. The 12in. pumps are each direct-coupled to a 30-b.h.p. motor, and will deliver 150,000 gallons of water per hour. The 15in. is coupled to a 50-b.h.p. motor, and will deliver 300,000 gallons of water per hour. The height of lift varies about 9ft. with the state of the tide, but the maximum is not greater than 15ft. A 36in. steel pipe is laid between the pump-house and the generating station, connections being provided for the ultimate requirements of about 12,000 h.p. The discharge pipe, which is of similar size and material, is brought back to the river higher up, the discharge being brought below low-water level to get the benefit of the siphon action. Two sets of Gwynne-Sargent motor-driven patent charging apparatus are also provided in the pump-house for priming the pumps. Each main engine is provided in the basement with a separate condenser having 2,350 square feet of cooling surface, and an electrically direct-driven three-throw Edwards air-pump. The discharge from the air-pump gravitates into a large cast-iron tank in the boiler-house basement, and is lifted from thence to the hot well over the feed-pump house by means of electrically-driven centrifugal pumps. An exhaust steam grease separator is placed between the engine and the condenser, each engine being also provided with an atmospheric exhaust controlled by an automatic valve, which opens in the event of the vacuum failing, so that the sets can run non-condensing.

Three-Phase Plant.

Energy is transmitted at 6,000 volts three-phase to a sub-station at the Fortwilliam depôt (Figs. 9 and 10) for operating portion of the system in that district, and for the supply to the Cavehill and Whitewell Tramway Company for their line. Two 250-kw. three-phase synchronous motor-generators are at present erected in the power station. These machines are supplied with continuous current from either the traction or lighting switchboards at a pressure of 500 to 550 volts, and generate three-phase current direct at 6,000 volts, 50 cycles. The alternating-current three-phase generators are of the Westinghouse 12-pole revolving-field type. The direct-current motors are six-pole coupled to the generators on a compound bed-plate. An exciter is provided on one end of the shaft for supplying the alternating-current field current; the speed of the set is 500 r.p.m. Three 125-kw. three-phase synchronous motor-generators are erected in the sub-station. These are similar to the 250-kw. sets, with the exception that each is provided with a small three-phase induction starting motor mounted on the other end of the shaft. The efficiencies guaranteed for these machines are as follows, the efficiency being taken as the ratio of the direct-current input to the alternating-current output:

Load.	250-kw. set.	125-kw. set.
1	87 per cent.	83½ per cent.
¾	86 ,,	82 ,,
½	82 ,,	78 ,,

The three-phase switchgear is of the Westinghouse well-known type. The chief feature of the high-tension portion is that all live parts are isolated from the operator, and fire risk is reduced to a minimum. All metal conductors are entirely enclosed in masonry cubicles, so that in the case of fire originating in one of these cubicles it is entirely confined to it. The oil switches are of the remote-control type, with a separate double-break switch in each phase. Each switch is entirely enclosed in a masonry structure, this separating it from adjacent phases. The switches are automatically opened by means of a trip coil, energised by means of series transformers placed in the main circuit. Duplicate three-phase 'bus bars are provided, to which the various generators and feeders are connected through selector switches, so that either 'bus bar can be made dead for cleaning or other purposes. Provision is also made for starting these motor-generators from the direct-current side. The sub-station is situated about three miles from the generating station, and is connected by means of a duplicate extra high-tension three-core trunk main, the section of each core being 0·075 square inch. These are lead-covered and armoured, and laid in earthenware troughs filled in with solid bitumen.

Switchgear.

The main traction switchboard and the three-phase operating switchboard are erected on a gallery which runs the full length of the engine-room at a height of 12ft. above the main floor-level. The main traction switchboard consists of three 500-kw. and three 1,000-kw. generator panels; one totalising panel; one Board of Trade panel; eight feeder panels, each for two feeders; one auxiliary power and lighting panel. The panels are of white Sicilian marble 2in. thick, the over-all height being 92in., the total length of the traction board being 50ft. Each generator panel is provided with a Bertram Thomas magnetic blow-out circuit breaker, a Weston illuminated-dial ammeter, three generator switches, and a Thomson integrating wattmeter. The totalising panel has mounted on it one Thomson integrating wattmeter (10,000 amperes), one Weston illuminated ammeter (10,000 amperes), four Weston illuminated ammeters for rail returns, two extra large Weston illuminated voltmeters on swing brackets for indicating the 'bus-bar and machine voltage. The Board of Trade panel has mounted on it one Elliott recording ammeter (10,000 amperes), one Elliott recording voltmeter (750 volts), two Elliott recording voltmeters (0 to 10 volts for rail drop), one Elliott recording ammeter (0 to 10 amperes), one Weston ammeter with double scale 0 to ·05 and 0 to 5 amperes; also the necessary multiple-contact switches for taking the line leakage tests on the various routes and multiple-contact switches for getting the rail drop between any of the four earthed points of the track and any of the route termini. Each feeder panel has mounted on it two Bertram Thomas magnetic blow-out circuit breakers, two Weston illuminated ammeters, two single-pole quick-break switches, two Thomson integrating wattmeters, and two Wurtz lightning arresters and kicking coils. As each route is supplied by a separate feeder, the energy used from day to day on any route can be ascertained, and valuable information obtained regarding the operation under different conditions. A main three-pole throw-over switch in the circuit of each generator is mounted on a pedestal on the floor below the switch gallery for connecting generators to the traction switchboard as compound machines, and to the lighting switchboard as shunt machines. The shunt resistances are mounted below the gallery floor, and are operated by means of hand-wheels erected in convenient positions in front of the switchboard.

Overhead Equipment.

The overhead equipment was carried out by Messrs. J. G White and Co., and the greater portion is of span-wire construction, with the exception of 2½ miles of side bracket, on outlying districts, and 2¾ miles of centre-pole construction in the wide main thoroughfares in the centre of the city. The poles are of lap-welded mild steel of the sectional type to the British standards specification. The pole fittings are of pressed steel, all straps, bolts, and nuts being galvanised. The poles are planted at the usual distance of 40 yards apart, the holes being filled in with 5 to 1 Portland cement concrete to a radial depth of not less than 8in. around the pole. The trolley wire is of hard-drawn copper 0·4in. diameter, with a breaking strain of 24 tons per square inch. The trolley wire, which is double throughout, is fixed at a height of 22ft. above the track, flexible suspension being adopted in all cases, and it is arranged for centre running on all span work, the maximum deviation allowed in any case being 6ft. from the centre of the track. On curves the wire in no case assumes an angle of less than 160deg.; 18in. ears are employed on the straight, and 30in. and 33in. ears on

Digitized by Google

curves. The sectional curves are of the straight under-running air-gap pattern, and are capable of standing a strain of 4,000lb. The span wires are of $^{7}/_{12}$ S.W.G. galvanised steel, with a breaking strain of not less than 4,000lb. Duplicate insulation is employed throughout. The insulator bolts are ¾in. diameter, and both insulators and Brooklyn strains are capable of withstanding a strain of 6,000lb. Guard wires are of $^{7}/_{16}$ S.W.G. galvanised steel with a breaking strain of 2,500lb. Guard wiring, however, has been reduced to a minimum, owing to the Corporation, on the advice of Mr. M'Cowen, having required the Telephone Company to put all their telephone wires on tramway routes underground. This, it is expected, will considerably minimise troubles with the overhead equipment. Section feeder pillars are placed half a mile apart on all routes, and at shorter distances in the centre of the city to suit local conditions. The section and feeder pillars are arranged for double insulation, and are provided with the following switchgear: two 400 and four 200 ampere quick-break switches, one 'bus bar of one square inch section, one lightning arrester and kicking coil, one terminal board for telephone and test wire terminals, and one telephone plug box. The current density for all switches and connections is 500 amperes per square inch. A small separate door is provided for getting to the telephone plug boxes, and owing to trouble from damp experienced with telephone instruments placed in pillars, the usual method has been departed from, and plug boxes only are provided in the pillars. The instruments themselves are provided with an induction coil in the handle, and an instrument is taken on each car, which can be plugged on to any pillar, and communication made with the power-house or car-sheds as desired. The centre poles are lighted by means of two incandescent lamps fixed on each pole at a height of about 12ft. from the ground; these are simply for the purpose of indicating the position of the poles at night, and not for street-lighting: they are supplied from the lighting mains. Provision was made for erecting arc lamps on the centre poles for street-lighting, but this matter has been deferred for the present. The overhead equipment in the six car-sheds and the approaches to same has been carried out by Mr. M'Cowen's own staff. Mechanical ears have been employed throughout this work, which has resulted in a considerable saving in cost, and gives excellent running. In some of the larger sheds one trolley wire is arranged to serve two lines of track. This method has been adopted with a view to reducing complications in the overhead special work, and as in one case as many as 17 tracks are taken off the two approach tracks, and in another 20 tracks are taken off a single track, the possible complications of overhead equipment can be imagined. The overhead wiring of each shed is separated from the street wiring by sectional insulators, and the supply of energy to each shed is controlled by a circuit breaker and wattmeter, so that the energy used in the sheds can be carefully watched and the outside lines protected from interruptions due to faults in the car-sheds. The approaches to each shed are brilliantly lighted by means of arc lamps supplying from the lighting mains where these are available, and in the other case from the tramway supply.

Underground Feeders.

The feeder cables are of Callender's well-known bitumen insulated type, laid in earthenware troughs run in solid with bitumen, the troughs being covered with hard-burnt tiles. Two cables only are laid in each trough, the arrangement throughout being the feeder together with the telephone and test wire for the same route placed in the same trough. There are 16 line feeders and four return feeders, the system of distribution being a line feeder for each route and two line feeders to the central district of the city. The rail return feeders are taken to four of the principal junctions, and are connected to the rails at these points through special switch pillars provided with a maximum demand indicator to register the earth-plate current, and an ammeter, together with the necessary switchgear and battery for testing the condition of the earth-plates which are placed at these four points. The rails are not earthed at the generating station, and neither positive nor negative boosters are at present employed in connection with the distributing system. The length of the feeders vary from 1,500 yards to 7,500 yards, and the section varies from one square inch to ·15 square inch of copper. The section of the rail return feeders varies from 2½ square inches to 1½ square inches, depending on the load in the various districts. All cables were subjected to the specified pressure test of 2,500 volts, and short lengths after being submitted to the usual bending tests failed to break down with 30,000 volts. These tests were carried out in the presence of Mr. M'Cowen at Messrs. Callender's works. Spare ways, "Sykes conduits," have also been laid to various junctions throughout the system, with a view to increasing the feeder capacity at a future date should the development of the undertaking require it. The supply and laying of the feeder cables were carried out by Messrs. Callender's Cable and Construction Company.

The contract for the whole of the work, with the exception of the buildings, was placed with Messrs. J. G. White and Co., London, on Dec. 1, 1904, the sub-contractors being: rails, North-Eastern Steel Company; special track-work, the Lorain Steel Company; feeder cables, Callender's Cable Company; engines, Combe, Barbour, and Combe; electric generators and switchgear, Westinghouse Company; boiler-house plant, Babcock and Wilcox; car bodies, Brush Company; car electrical equipment, Westinghouse Company.

In the supervision of the electrical equipment of the system Mr. M'Cowen was ably assisted by his deputy (Mr. Bloxam) and his tramways distributing assistant (Mr. Croft). The total cost of the undertaking, including cost of works, award of arbitrator, and expenses, is close on £1,000,000.

TORQUAY ELECTRICITY SUPPLY.

Local Government Board Muddle.

The following correspondence will, in our opinion, show to any intelligent electrical engineer the hopeless muddle that the Local Government Board has made over the Torquay applications for loans for extensions. Our conclusions as amplified in our leading article are as follows:

1. That the Local Government Board after all these years of experience has acquired no knowledge whatever as to the effect of load factor on the cost of production.
2. That it wants business men as inspectors, rather than engineers with only sufficient knowledge of the subject as to be examples of the old proverb.
3. That the Local Government Board fancies itself above Parliament, whereas it is only a branch department, not entitled to reverse parliamentary decisions.

The letters are not the complete correspondence, but suffice to show the trend of the same. The net result is an immediate loss of over £1,000 to the Torquay Corporation, a further loss of £3,000 when the new plant has to be moved, and a further loss most difficult to estimate, due to the fact that no new consumers of any magnitude can be connected for some years to come.

"Local Government Board,
"March 21, 1905.

"Sir,—I am directed by the Local Government Board to state that they have had under consideration the report made by their inspector, Mr. Hooper, after the inquiry held by him with reference to the application of the Town Council of Torquay for sanction to borrow £42,000 for purposes of electric lighting and power supply.

"The Board are advised that the present proposals of the Town Council would probably involve a serious loss to the borough for, at any rate, the first few years. Apart from this, the proposals involve the supersession of works at the existing power station and at the destructor, on which there is an outstanding debt of more than £8,700, and if the scheme were to proceed, the amount of this debt would have to be provided out of the current rates for the year.

"In these circumstances, and having regard to the present high rates in the borough, the Board think that the Town Council should seriously reconsider their proposals.

Digitized by Google

"It appears from the evidence given at the inquiry that the profits on the existing works of electric lighting amounted to £1,096 for the year 1904, and the inspector reports that, although the site of the power station is cramped, improvements could probably be effected there which would render the station sufficient for the supply of energy for lighting purposes for some years to come.

"I am to remind you that the cost of obtaining the electric lighting provisional order must not be charged to the loan account.—I am, etc.,

"(Signed) NOEL T. KERSHAW,
"Assistant Secretary.

"The Town Clerk, Torquay."

"The Dolter Electric Traction, Limited,
"3 and 4, Great Winchester-street, London, E.C.
"March 23, 1905.

"Frederick S. Hex, Esq.,
"Town Clerk, Town Hall, Torquay.

"Dear Sir,—I am instructed by my directors to inform your Corporation that on the occasion of the visit of our chairman, engineer, and contractors to Torquay, they found that nothing further had been done towards the work of preparation to furnish the electrical supply agreed upon between the Corporation and the Dolter Company.

"I beg to inform you, on behalf of the Dolter Board, that final arrangements are now made by the Dolter Company for commencing work, that they have placed orders for materials, etc., and will push on with all possible speed, and, further, be ready to take current from you the first week in August.

"Further, I am instructed by my directors to inform your Corporation that under the provisions of their Act of Parliament they will hold your Corporation liable for any loss sustained after the line is laid.

"Trusting that you will kindly place this letter before your Corporation without delay—I am, etc.,

"(Signed) H. LANCASTER,
"Manager of the Dolter Electric
"Traction, Limited."

"3 and 4, Great Winchester-street,
"London, E.C.,
"May 1, 1905.

"Fredk. Hex, Esq.,
"Town Clerk, Town Hall, Torquay.

"Dear Sir,—I have been instructed by my directors to write and inform you that in consequence of not having received any reply to my last letter, they wish to urge upon your Corporation the importance of letting us have a definite decision in regard to the supply of current for our tramway undertaking.

"I write this letter without prejudice to any action which we might take under the existing agreement between my company and your Corporation. But it would facilitate our commencing operations if you would let me know on behalf of your Corporation whether, in the event of their being unable to obtain the necessary consent of the Local Government Board for the erection of a new power-house, they would be prepared to let their lighting undertaking to my company, who would make a fair arrangement for sharing profits, etc. (which I should be prepared to discuss with you), and would also undertake to pay all capital charges. They would also make arrangements as to obtaining a supply of current in conjunction with the lighting undertaking.

"Should this not meet the views of your Corporation, the question, then, is whether they will at once give consent for us to erect our own generating station. We, of course, recognise that this would be a great loss to the town; but your Corporation, as business men, cannot fail to see that it is difficult to commence an undertaking of this magnitude without receiving definite replies as to our position in regard to the supply of current.

"We may point out to the Corporation of Torquay that, while we have been delayed over this question, we have carried through and are just commencing an equally large scheme connected with the Sheffield tramways at Rotherham.

"This delay is very trying to my directors, who are occupied on several other important schemes at the present time, and it is suggested that a conference might be held in a fortnight's time, when a definite result as to the policy of your Corporation should be arrived at.

"Awaiting your reply, and trusting there will be no delay in placing this letter before the members of your Town Council.—I am, dear Sir, yours faithfully,

"(Signed) H. H. LANCASTER,
"Manager of the Dolter Electric
"Traction Limited."

Resolution passed June 2, 1905.

"That this Council having, in accordance with the letter of the Local Government Board of March 21, 1905, seriously reconsidered the proposals contained in the recent application to the Board for sanction to borrow £42,000 for purposes of electric lighting and power supply, begs respectfully to inform the Local Government Board that, having by Section 58, Sub-Section 9, of the Torquay Tramway Act, 1904, agreed to supply electric energy to the Dolter Electric Traction, Limited, cannot now see its way to modify its application to the Local Government Board for sanction to borrow the sum of £42,000 save as hereunder set out, for the purpose of enabling it to perform the said agreement, as in case of non-performance thereof on the part of this Council, the Council might be involved in litigation and possibly found liable to pay heavy damages to the Dolter Electric Traction, Limited, and this Council respectfully asks the Local Government Board to consider the position in which this Council is placed by reason of the said agreement, which was fully discussed and approved by the committees of both Houses of Parliament, and further asks the Local Government Board to grant the application of this Council with the omission of the sum provided for the erection of a combined chimney, so that, in addition to the agreement above referred to being performed, the increased accommodation for the purposes of electric lighting so urgently needed may be provided."

"Local Government Board, Whitehall, S.W.,
"June 28, 1905.

"Sir,—I am directed by the Local Government Board to acknowledge the receipt of your letter of the 23rd inst., with reference to the application of the Town Council of Torquay for sanction to borrow £42,000 for purposes of electric lighting and power supply, and to state that the Board have carefully considered the representations in the resolution of the Town Council passed on the 9th ult., and in your letters, but they adhere to the view that the proposals of the Town Council would probably involve a serious loss to the borough.

"The Board realise the difficulty in which the Town Council are placed in consequence of the agreement entered into with Dolter Electric Traction, Limited, but it would appear from the letter from the company to the Town Council of May 1, a copy of which has been forwarded to the Board, that the company might be willing to enter into arrangements with the Town Council, by which the latter would be relieved from their obligations under the agreement.

"The Board think that the Town Council should place themselves in communication with the company with a view to some arrangement with this object being made if practicable.—I am, Sir, your obedient servant,

"(Signed) JOHN LITHIBY,
"Assistant Secretary.

"The Town Clerk, Torquay."

"Whitehall, S.W., August, 1905.

"Sir,—I am directed by the Local Government Board to advert to your letter of the 19th ult. with reference to the application of the Town Council of Torquay for sanction to borrow £42,000 for purposes of electric lighting and

Digitized by Google

power supply, and as regards your request to be furnished with particulars of the figures upon which the Board have arrived at the conclusion that the proposals would probably involve a serious loss to the borough, I am to make the following observations:

"At the local inquiry in January last the Council's electrical engineer submitted an estimate of the probable receipts and expenditure during the first year's working at the proposed new power station. The following is a summary of this estimate:

	£	s.	d.	£	s.	d.
Revenue—						
Lighting	7,493	8	6			
Tramways (based on 106 hours per week per car)	3,572	18	4			
				11,066	6	10
Expenditure—						
Interest and sinking fund charges	5,049	7	3			
Working expenses (based on an average cost of 1·38d. per unit sold)	5,694	0	0			
				10,743	7	3
Estimated surplus				322	19	7

"As regards the estimated revenue from tramways, the Board are advised that the basis of calculation—*viz.*, 106 hours per week per car—is excessive, and that the more probable figure for a place like Torquay would be 80 hours per week per car. Taking the latter figure as the basis of calculation, and allowing a corresponding saving in fuel, the estimated revenue from tramways would be, say, £2,858, or a reduction of 20 per cent. on the estimate submitted.

"As regards the working expenses, the Board are advised that the estimate of 1·38d. per unit, which is little more than one-half the actual cost at the present time, is too low. They find that at seven other towns in England of about the same size as Torquay, which supply power for traction purposes as well as for lighting, the average total works cost per Board of Trade unit is 2·15d., and some of these towns are better situated for obtaining cheaper coal.

"The Board think, therefore, that in order to arrive at a fairly accurate estimate, the average cost per unit sold should be taken at not less than 1·82d., which would then be a distinctly low figure for a place like Torquay, and a reduction of 41 per cent. below the present cost.

"Taking the amended figures for tramway revenue and working expenses as above suggested, the estimated revenue and expenditure would be as follows:

	£	s.	d.	£	s.	d.
Revenue—						
Lighting	7,493	0	0			
Tramway	2,858	0	0			
				10,351	0	0
Expenditure—						
Interest and sinking fund charges	5,049	0	0			
Working expenses	7,592	0	0			
				12,641	0	0
Estimated deficiency on first year's working				2,290	0	0

"I am at the same time to transmit to the Town Council the enclosed copy of a communication which the Board have received from the manager of the Dolter Electric Traction, Limited, and to inquire whether the Council concur in Mr. Mitchell's report. If so, the Board would be prepared to consider a scheme on the lines indicated, and I am to request that such a scheme may be submitted.—I am, etc.,

"NOEL T. KERSHAW, Assistant Secretary."

Report of the Torquay Council Meeting, Nov. 24, 1905.

The TOWN CLERK read the following important communication from the Local Government Board:

"Local Government Board, Whitehall, S.W.,
"Nov. 20, 1905.

"Sir,—I am directed by the Local Government Board to state that they have had under consideration the report made by their inspector, Mr. Hooper, after the inquiry held by him with reference to the application of the Town Council of Torquay for sanction to borrow the sum of £9,500 for purposes of electric lighting and power supply. The Board has decided to comply with the application so far as it relates to the borrowing of the sum of £8,099, and their formal sanction is forwarded to you herewith. In arriving at this amount the Board have deducted the following sums:

(1) Cost of taking down and removing 125-kw. alternator	£10
(2) Outstanding debt on such alternator	1,336
(3) Cost of removal of 40-kw. alternator	55
	£1,401

"As regards deductions (1) and (3) I am to explain that the Board do not regard these items as suitable subjects of a loan. Deduction (2) is made in accordance with the Board's usual practice in cases where works on which debt is outstanding are to be superseded. The Board will raise no objection to the application of any sum received from the sale of the 125-kw. alternator in defraying the cost of the new plant.

"The Board direct me at the same time to point out to the Town Council the desirability of postponing for the present any extension of the system of public lighting by electricity. The Board gather that this system is unremunerative, and, having in view the financial advantage of utilising the present generating station as long as possible, it is clearly inadvisable to increase the existing loan for any unprofitable purpose. Moreover, the Board consider that as the provision of a new generating station will no doubt ultimately be necessary, the Town Council should see that the undertaking is carried on with the greatest economy, and otherwise in such a manner that a substantial reserve fund may be built up to meet the anticipated large expenditure.—I am, Sir, your obedient servant,

"NOEL T. KERSHAW, Assistant Secretary."

Councillor MORTIMER, in moving that the communication be referred to the Electrical Committee, said no doubt there would be a certain amount of congratulation that the loan had been granted, but he felt that the larger scheme, with certain modifications, would have been much the better one.

Councillor KENNY seconded.

Alderman RUTLAND asked how the £1,400 was to be made up.

The TOWN CLERK: That is a matter for the Electrical Committee to report upon.

The motion was carried.

Councillor ROCKHEY said there was a rumour about that there had been an offer made to purchase the electrical undertaking. Was it correct?

The TOWN CLERK: If you have patience, you will hear something about it at a future meeting.

Councillor ROCKHEY: I have patience, but I wish to know if it is correct.

Alderman PEARSON: Yes.

ELECTRIC LOCOMOTIVE FOR UNDERGROUND RAILWAY.

The electrification of the Underground Electric Railway Company's line has been extended as far as Earl's Court

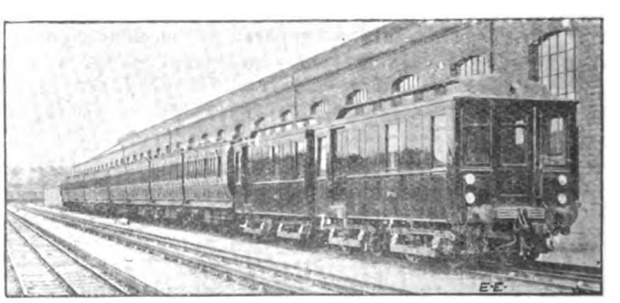

FIG. 1.—L. and N.W. Train with Electric Locomotive.

and on Saturday the new electric locomotives for drawing the London and North-Western trains were introduced for the first time. The trains are now driven electrically from the Mansion House to Earl's Court, at which place the electric locomotive is shunted (the train proceeding on its

Digitized by Google

journey with a steam locomotive), and used for driving another train to the Mansion House on the return journey.

simply taking one of the B.T.H. standard equipments supplied for their underground trains and applying it to

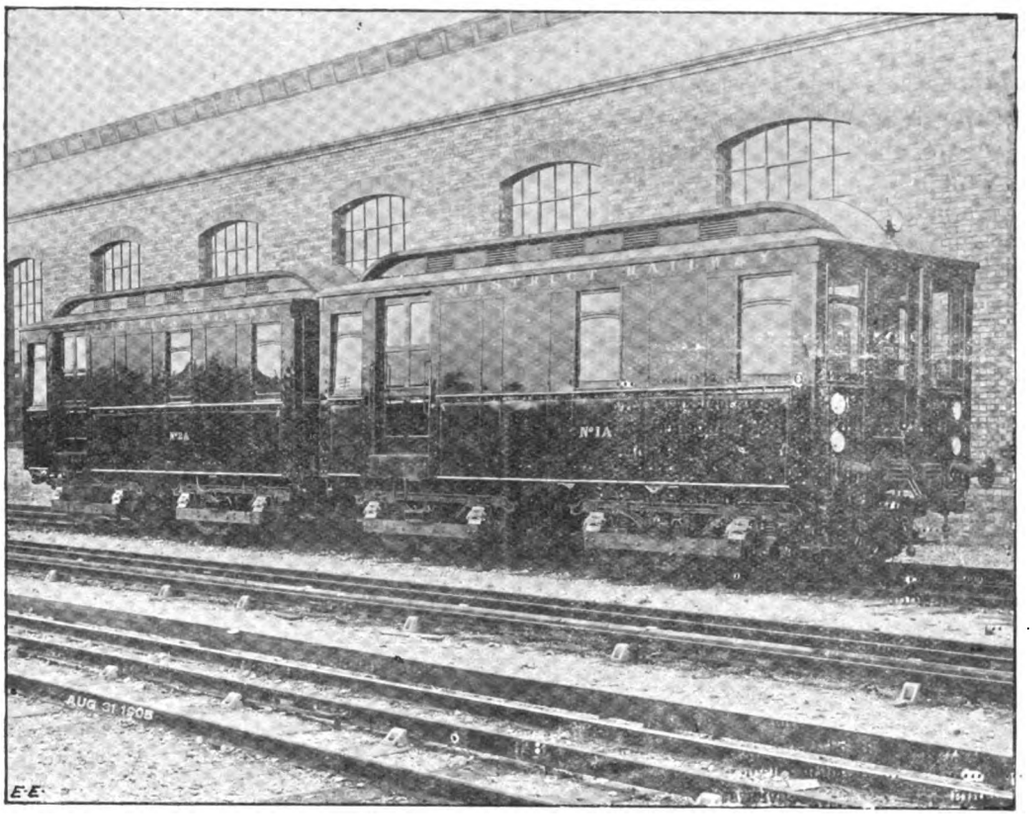

FIG. 2.—District Railway Company's 800-h.p. Electric Locomotive for hauling L. and N.W. Trains.

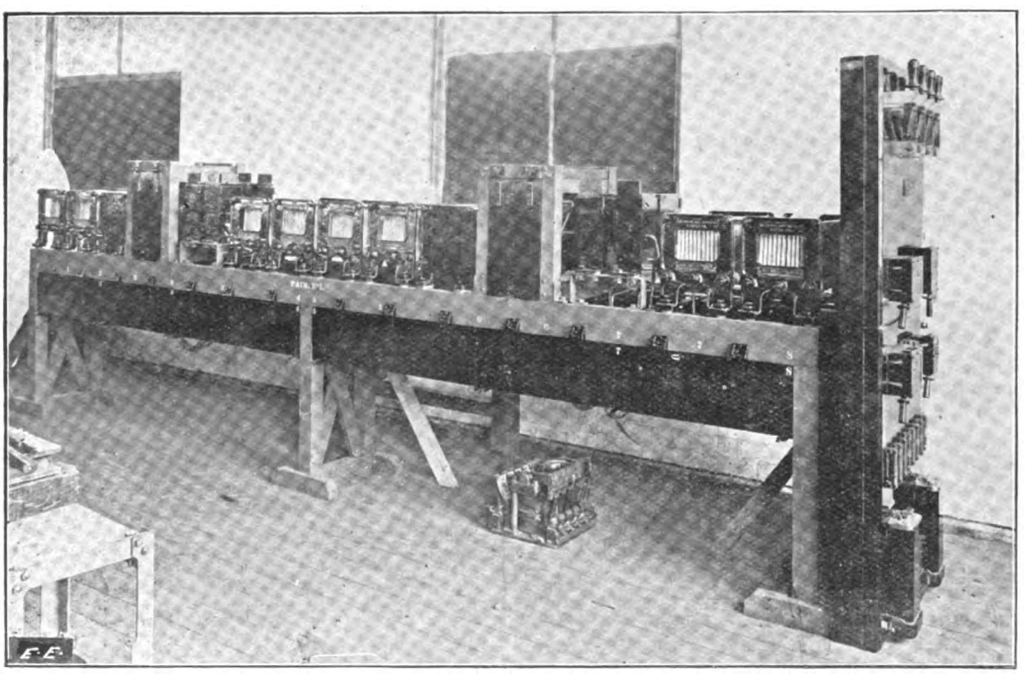

FIG. 3.—Arrangement of Contactors, Switches, Circuit Breakers, and Reversers.

The locomotives were built by the Amalgamated Railway Carriage and Wagon Company, Limited, of Saltley Works, Birmingham, and each is provided with motors of 800 h.p., the weight of the London and North-Western train with load being 140 tons (Figs. 1 and 2). There are four 200-h.p. motors of the B.T.H. G.E.-69 type on each locomotive, similar to those used on other underground trains. The Sprague Thomson-Houston system of train control is in operation, and each locomotive is furnished with a double equipment, consisting of two sets of contactors, circuit breakers, reversers, etc. The photograph (Fig. 3) shows the arrangement of the open equipment. This is the same as has been in operation for some time, the Underground Railways Company of London, Limited, the locomotive. The combined weight of each locomotive is about 56 tons, or seven tons on each driving axle.

Hydro-Electric Plant.—The *Diario Official* of Mexico of Oct. 30 notifies an application by Señor Salvador Gambino for an appropriation of 10,000 litres of water per second from the river San Pedro, in the State of Chihuahua, for the purposes of irrigation and production of motive power. The *Diario* of Oct 31 notifies an application by Señor Felix Araiza for an appropriation of water from the river Bolaños situated between the State of Jalisco and the territory of Tepic, for the production of motive power. The *Diario* of Nov. 2 notifies an application by Señor L. del Paso for an appropriation of 9,000 litres per second from the waters of the rivers Chinipas and Septentrión, in the States of Sonora and Sinaloa, for the production of motive power.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

POOR TORQUAY.

The Torquay Corporation, and, unfortunately, the Torquay ratepayers also, are to be commiserated with in the straits to which the Local Government Board have brought them. We believe it was Sydney Smith who said, "A corporation has neither a body to be saved nor a soul to be damned." Whether we are correct or not in our quotation, it is certainly the case with the Local Government Board, because the Board, although powerful in doing mischief, has no existence. As it is impossible, therefore, to libel a Board which does not exist, we feel quite free to express our strong opinion on the decisions issued in the name of that Board. If certain of the permanent officials, or even the outgoing political chief, should take these remarks as personal, we shall be exceedingly vexed. If, however, they will induce the permanent officials to study the subject which their very appointments suppose them to be expert in, our object will have been gained. Certain of our readers may not have followed our leading articles on the procedure of the Local Government Board when considering electric lighting loans. We would ask them to read the three leading articles for Nov. 3, 10, and 17, entitled respectively "The Local Government Board and Electrical Undertakings," "Local Government Board Loans,' and "Engineering Estimates and the Local Government Board." They would also do well to read the letters which have passed between the Board and the Corporation of Torquay which appear in this issue, together with a few letters from the Dolter Electric Traction Company, Limited. We took care that the leading articles above referred to should be brought to the notice of the chief of the department of the Local Government Board dealing with the Torquay matter, and we also sent the papers to Mr. Ross Hooper, the inspector who held the two Torquay inquiries. We are somewhat surprised, therefore, to find that the final decision of the Board should be such as to perpetuate for a time at least an inefficient station for the generation of electricity. After the letters in question will be found a report from the *Torquay Times* of the last meeting of the Council. It was asked what the Electricity Committee proposed to do as to that portion of the loan which the Board would not sanction—*i.e.*, one thousand four hundred and one pounds. We can answer this question. This sum, less any moneys received for the old machinery sold, will have to be borne out of revenue. This looks like an immediate loss of about one thousand pounds for the removal of machinery which if left in its present position would continue to earn profits until such time as a new station can be erected. For this loss the Local Government Board are directly responsible because they have sanctioned the removal of the machinery. Further, they have granted a loan for eight thousand and ninety-nine pounds for new machinery and alterations to the old station to enable this to be put down. As we showed in our leader of Nov. 10, the Board had the evidence of the well-known expert, Mr. E Manville, that two or three years would be the probable time in which the load would outgrow the capabilities of the altered station. Hence, in, say, three years' time, as we then explained, some three thousand pounds worth of the present expenditure will become valueless, as the machinery now installed will then have to be moved into a new station elsewhere in the town, where economical running will be possible. The Local Government Board hides these facts away, and grants the new loan for fifteen years. At the end of three years it is true that the present expenditure will stand on the books at four-fifths of its present value. This depreciation, however, is required to meet the presumed

Digitized by Google

replacement of the plant in fifteen years, and does not affect the three thousand pounds' loss in its removal in three years' time. The Local Government Board have, therefore, forced the Corporation to take one thousand pounds from revenue this year, and at the end of three years they insist, if they follow their unbroken precedent, in a further loss of three thousand pounds being met by revenue. This total loss of four thousand pounds is, however, a small matter compared with the other recommendation in the last letter sent to the Corporation. In it they are told not to extend their street-lighting because it is unremunerative, and, reading between the lines, the Corporation have little chance in extending their private consumption either, because the altered plant will not be capable of meeting much more load than that required for the tramways. The letters we publish will show that the Board and some of its inspecting engineers are as ignorant as even our gas contemporaries of the true method of ascertaining what it costs to supply any particular type of load. They are, therefore, quite incapable of saying what is and what is not a profitable price to charge either for street-lighting or tramway supply. They have not sufficient business knowledge to know that a parliamentary power supply company with a million pounds of capital on paper may not have enough money in the bank to meet their office expenses. Such lamentable lack of business capacity makes one wish that the late Sir Courtney Boyle could be again in charge of the Department. We remember that once a company promoter, wishing to get the transfer of the Fleetwood electric lighting order, sent a deputation of the Corporation to Sir Courtney Boyle, with the certificate of registration of the company as evidence of financial stability. He promptly requested them to "Take away that —— picture"—and we need hardly say that the application for transfer was not granted. We hope that with the change of Government the political head of the Board of Trade will not be the only change made in the personnel. It is quite time that such an important department was reorganised, so that at least there may be some chance of the staff understanding the subject with which the Department has to deal.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC FIRES (?)

SIR,—I notice in the newspapers this morning that the cause of the fire at the Shrewsbury Schools is put down to the fusion of the electric light wires. I have thoroughly investigated the matter both yesterday and to-day, and can say positively that this was not cause of the fire. The whole of the branch fuses were in order in the distributing boards (which were not damaged by the fire), showing that the damage to the wires was the effect of the fire, and was done after the main switches were turned off. The fire is supposed to have started some distance from any electric light wires, and close to the flue leading from the heating apparatus. The report in the newspapers has come from no reliable source.—Yours, etc.,

C. M. JOHNSTON, M.I.E.E., Borough Electrical Engineer.
Shrewsbury, Dec. 6.

EXCESS PRESSURE ARRESTERS.

SIR,—In reply to "G. M.'s" letter, the resistance of the jet (when used in combination with excess pressure arresters) should be such that about 500 watts flow to earth. These jets are frequently used as lighting arresters, in which case a constant current of 0·1 to 0·2 amperes is allowed to flow to earth during the thunderstorm. Used in this manner, in addition to the ordinary horn type arrester (the jet resistance being in this case in parallel and not in series with the horn arrester), these jets form one of the best protections against lightning. Indeed, they are the only forms that are really effective in such severe thunderstorms as are experienced in tropical countries.

Voltage.		Sections of jet.		Height of jet.
20,000	.....	150 square millimetres	.....	350 millimetres
12,000	.....	250 " "	.....	250 "
8,000	.....	300 " "	.....	200 "

I give a table showing section and height of jet to allow 0·1 ampere to flow to earth. The sections must not be reduced, or the jet will not satisfactorily take the flash to earth.—Yours, etc.,

ZODIAC.

Nov. 30, 1905.

THE NEW BOSS: AN OLD, OLD TALE.

The Boss.
The new Boss.
What like is he?
And the answer was forthcoming:

> "Gin his breeks was red, and he'd no sic an awfy swelled heid, he'd be Mephisto. Black een, black whiskers, sallow, dour, and sarcastic."

But
What *says* he?

> "Tae the Works Supt., 'Whit time d' ye start yersel?' 'Eight!!' 'Start wi' the men when the horn blaws'"!

Collapse.
Painful and speechless collapse.

> "Tae the ower-wrought Chief Drn., 'Ye're owerstaffed, and owerpaid. Sack the hauf, use apprentices, and consider yer screw doon fifty quid,' says he."

Horrors!!
What says he to
The outside erector?

> "'Stannin aroond watchin'? Ye re a' lazy thegither. Cud a fitter no dae this job?' And yon erector chap up and tells him, 'Just as pleases yersel: I didna *ask* for the d—— job'"!!

H'm. H'm. Things looking up a bit.
Then he hies him unto
The Works Draughtsman.

> "'Ma conscience, na wonder dividends is doon, makin' yer ain tools when ye cud get them for the hauf frae some ither fowk. 'Ye cudna, and onywey gin ye think ye cud dae the job better yersel, here's ma notice"!!!

?!! — — ?!!!
Oh rapture, oh ecstasy.

Moral!—It's a strong man who can run a shop single-handed.

ELECTRO-CHEMICAL DEVELOPMENTS.

In the *Electrical World and Engineer* are described some electrolytic processes which have recently been patented in America.

Metallic sodium is made commercially at Niagara Falls by the Castner process, which electrolyses caustic soda in a single cell. A patent recently granted to Mr. E. A. Ashcroft proposes the use of a double cell, which in some respects resembles the Castner-Kellner and the Acker cells for electrolysis of sodium chloride. As in the Castner-Kellner process, Mr. Ashcroft uses an intermediate bipolar electrode, which forms the connection between the two cells; but he electrolyses fused salt, and, therefore, cannot use mercury for the bipolar electrode, but uses instead fused lead, as is done in the Acker process. In this first compartment Mr. Ashcroft electrolyses fused sodium chloride. The sodium set free by the cathodic reaction alloys with

Digitized by Google

the fused lead, and is transferred into the second compartment, where it passes again into the electrolyte, which is fused caustic soda. In this cell metallic sodium is then obtained as a cathodic product. Another process in which a fused electrolyte is employed is described in a patent of Mr. H. S. Blackmore. It may be best described in its application to the production of a copper-aluminium alloy. Copper aluminate is dissolved in a fused mixture of lithium and calcium oxides, and on electrolysis of this fused solution a copper-aluminium alloy is obtained. In all metallurgical processes, metals are purified by means of slags which combine with the impurities and thus remove them from the metallic bath. A modification of this method is proposed in a recent patent of Mr. H. M. Chance, who holds the metal in molten state in contact with an electrolyte which on electrolysis yields the purifying agent. Thus he proposes to purify molten iron by making it a cathode, in contact with fused calcium chloride as electrolyte; calcium is then set free by the current and serves as a purifying agent. Chlorates are made commercially by electrolysis of aqueous solutions of the chlorides in a cell without a diaphragm at a temperature of about 70deg. C.; this process is in use by the National Electrolytic Company at Niagara Falls. A process recently patented by Mr. A. E. Gibbs yields simultaneously chlorate and bichromate. It depends upon the reaction between chromate and chlorine gas, yielding bichromate, chlorate, and chloride. Either a stream of chlorine gas from a reservoir is pumped through a solution of chromate, or the chlorine is electrolytically formed in a cell itself. In the latter case the cell contains both chromate and chloride, and a diaphragm cell is employed.

MANCHESTER SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

Chairman's Address.

BY S. L. PEARCE, M.I E E.

(Concluded from page 778.)

Central-station engineers are gradually becoming to recognise more and more the value of steam-turbine plants. The more extensive adoption of these plants, the larger sizes of units used, on which so much emphasis has of late been laid in the technical Press, mark the chief progress of power station developments. An extended use of three-phase plants has been inevitable, and to these steam-turbines are particularly suitable. Of the many good qualities appertaining to the turbine it is unnecessary at this stage to refer, but mention may be made of some extremely good steam consumption tests that have recently been made. With units of 3,000 kw. capacity, 15lb. to 15¼lb. of steam per kilowatt-hour at full load and 16·75lb. at half-load have been obtained. It is interesting to note, further, that steam consumption trials conducted on turbines after having been at work for extended periods give results which show no falling off in efficiency from the results obtained on official tests. This is a point concerning which some doubts have been hitherto expressed. Reciprocating sets are still being built in large sizes, but it is not surprising to note that the general trend is all in favour of the adoption of turbines, especially for large units. The past year has, however, marked a real development in the design and manufacture of turbine-driven continuous-current generators. It is not so very long ago that the difficulty of solving in a satisfactory manner the commutation problem was considered a barrier to their adoption. With high speeds it is impossible to keep down the reactance voltage; with slow-speed sets, on the other hand, carbon brushes fulfil all the necessary requirements, and special means for counteracting the armature reaction are not necessary. Two methods are in vogue successfully to-day for compensating for armature reaction on high-speed sets: (1) compensating coils wound in slots in the pole-pieces, thus neutralising the armature effect on the field; (2) auxiliary or commutating poles arranged between the ordinary poles. Both systems have given satisfactory results in practical operation, and whilst the latter is the more mechanical arrangement, the former has advantages from an electrical point of view. Another departure from generally accepted practice has been made recently in the use of carbon brushes for turbine-driven generators. Engineers have been generally familiar with the wire brushes and serrated commutators hitherto considered to give the best results, but it must be allowed that the smooth surface commutator and carbon brushes form a far more mechanical piece of work, and it is hoped that equally good results may be obtained from an electrical point of view. Such continuous-current sets provided with carbon brushes are in operation now for the first time in this country on lighting and traction circuits. Towards this improvement the present manufacture of carbon brushes has contributed considerably. The introduction of copper, either mixed with or graded with the carbon, give to the brush those qualities which facilitate commutation.

The gas-engine has hitherto found little favour for central-station work in this country, and the threatened supersession of steam plants has still to come, and, until put forward in the form of the gas-turbine, is not likely to oust the steam-turbine, in view of the very large units being adopted in central stations to-day, and the uncertainty that prevails on the score of satisfactory parallel running with gas plants coupled to alternators. Much, however, has been done recently in the development of gas-engine building, and units of 3,000 h.p. have been constructed. Electrical engineers are not unmindful of the main economy that is possible with the use of gas plant as compared with steam plant, and of the many improvements that have brought the gas-engine to a much greater degree of perfection, but it cannot be said yet that the day of large power gas-engines—*i.e.*, engines of 2,000 h.p. to 3,000 h.p.—has fully come. However, the outlook for their use is more favourable to-day, but we still appear a long way off from the time, so often prophesied, when the gas-engine will completely supersede the steam-engine as a prime mover. The conditions which militate against the adoption of gas plants for large power stations as compared with turbine plant may be briefly stated as follows: (1) The higher initial capital outlay. Taking a station of 20,000 h.p. to 30,000 h.p. gas plants could not be installed under £18 per kilowatt, exclusive of buildings. A modern steam plant could be put down for two-thirds of this amount, and, in fact, a figure of £8 has been taken in one notable instance. (2) Increased floor space required. (3) Probably higher rate of depreciation and increased maintenance costs. Against these may be put in favour of producer gas plants: (1) The saving in actual fuel, which, of course, varies under different conditions, but is not likely to be less than 15 to 20 per cent. (2) The saving due to the recovery of the sulphate of ammonia. The combination of the latter, however, with high-tension plants is not one that commends itself to electrical engineers.

As illustrating the growth of electricity supply stations, it may be of interest to state that the total capital invested has increased from, roughly, £8,000,000 in 1896 to £62,000,000 at the end of last year, represented by 183 companies and 262 municipalities, the total capital being approximately evenly divided between the two classes of undertakings. Whatever the critics may have to say on the subject of municipal trading, it is evident that the electrical industry is, at any rate, indebted to it. Of this £62,000,000 some 42 per cent. has been spent on the engine and boiler house equipments of the generating stations, and some 35 per cent. on the feeding and distributing systems. These figures indicate the very great importance of electricity supply, in regard to which no signs of diminution are manifesting themselves. An increase in the last decade of nearly 800 per cent. in capital, of 1,000 per cent. in lamp connections, and of 1,500 per cent. in the number of units sold, are figures which will speak for themselves.

In the domains of the electro-chemical and electro-metallurgical industries, reference should be made principally to the improvements that have been made in the methods of iron and steel production. The earlier attempts to substitute purely electrical methods in the reduction of the iron ores for the more usual process of smelting have not been very successful, and at present the electrical furnace cannot be considered a serious rival to the blast furnace. The trend of events has, however, been towards improvements in the furnaces and methods for producing steel and alloys from pig iron and scrap. It is possible that in the near future the combination of blast furnaces with electric steel refining furnaces will be considered indispensable to all up-to-date steelworks. The opinion of the commission appointed by the Canadian Government as far as they are capable of application to this country is worth quoting: "That pig iron can be produced from iron ore, and steel of all grades can be produced in the electric furnace from pig iron, scrap, and ores as easily as by the customary methods, and that the high-grade classes of crucible steel and special alloys can be made with marked economy in several forms of electric furnaces.' The manufacture of pig iron in the electric furnace is of little interest to electrical engineers in this country, as with the cheap supply of fuel available here no electric furnace can compete with a modern blast furnace. It is not improbable that the electrical energy required for the electric furnaces will be obtained from gas-engines operated by gases from the blast furnaces. Probably only two of the modern electric furnaces are capable of adoption for English steel smelting, but it has been proved that either of these processes can compete successfully with the Sheffield crucible furnace with electrical energy

Digitized by Google

at anything like a reasonable figure. Aluminium has had an extended use in connection with the "Thermit" process of welding tramrails, which is being successfully adopted by many of the larger municipalities.

In the telegraph world there is a growing tendency to introduce typewriting telegraphs and machine telegraphs which reproduce the written message in its original form. Electric signalling is being adopted by the principal railways, and during the year an important installation has been put down at Derby on the Midland Railway. The system is purely electrical, and not a combination of electrical and pneumatic devices. Both points and signals are operated by specially constructed motors. The system includes a mercury contact under the running rail, whereby a passing train puts a signal to danger after passing it. Automatic signalling systems are also finding favour on electric railways, where the presence of a live rail makes the provision of energy for the signals a simple matter. In the field of wireless telegraphy much useful work has been done in popularising the system by the acceptance of messages at post offices for transmitting to vessels at sea, and *vice versâ*. Licenses are now required for the setting up of stations to avoid interference with other stations which may be near. In certain cases these licenses are refused, but permission is given to erect elsewhere. The common battery system is now practically standard for all large telephone exchanges, and the National Telephone stations are being changed over to it. The chief event of the year is the ratification of the agreement between the Post Office and the National Telephone Company, whereby the former purchases the system of the latter in 1911. By this arrangement municipalities are prohibited from taking out further licenses, and the existing municipal systems can be purchased outright. Some interesting figures were produced in the hearing of the evidence before the Telephone Committee. At the end of March, 1905, the National Telephone Company had 1,139 exchanges, 320,017 subscribers' stations, and were handling 995 million messages per annum; 683,000 miles of wire were in use, of which 64½ per cent. were underground; 45,000 miles of underground wires were rented from the General Post Office. Important improvements have been made during the year in the manufacture of domestic and short-distance telephones. Intercommunication systems for office, warehouse, and works use can now be obtained at much lower prices than formerly, and a healthy competition has been the means of bringing the telephone within the reach of the smallest concerns. Continental communication is now possible, and steps are being taken to extend the lines into countries far inland.

From an electrical engineer's point of view, the last session of Parliament has not been remarkable for the legislation that has been enacted. The question of a cheap power supply for London in the form of the "Administrative County of London Power Bill" has been the predominating feature. With the details of the Bill many of you are no doubt familiar. The scheduled area of supply covered by the provisions of this Bill was no less than 600 square miles, and was divided into portions—the industrial and non-industrial. In the former, powers were sought to supply tramways, railways, docks, Government offices, etc., and also to individual consumers with the consent of the existing authorised distributor. In the event of that consent being withheld, an appeal to the Board of Trade was to follow. In the non-industrial area, powers to supply in bulk, and to tramways, railways, docks, etc., were asked for, but not individual consumers. The Bill, as amended, commended itself to a large proportion of the original opponents—viz., the supply companies—which is evidenced by the various agreements which were arrived at between themselves and the promoters of the Bill. Whatever views we may hold as to the fairness or otherwise of allowing a company armed with such powers as this Bill would have given it coming into competition under conditions favourable to themselves in the same areas with the existing pioneering supply companies and local authorities working under unfavourable conditions, we cannot but regret that this and similar measures should be prevented from becoming law simply by the elapsing of time, and that all the money and labour spent on their promotion should be lost. Evidently there is considerable room for improvement in the method of parliamentary procedure, and there does not appear any valid reason why the various Bills should not be taken up at the new session of Parliament at the stage at which they were left in the preceding session. The "Supply of Electricity" Bill has been introduced for the fourth occasion only to be dropped again. This is certainly a misfortune, as in its present form it is certainly more favourable as regards both powers and restrictions in so far as these apply to local authorities. In particular the provisions made (1) for the compulsory acquisition or use of land for generating stations allows of the operation of a generating station without unreasonable risk of being subject to a nuisance clause, and (2) the stand-by clause, under which a person is not entitled to demand or to continue to receive a stand-by supply unless agreeing with the undertakers to pay a reasonable return on the capital expenditure incurred, is one which is urgently required. Of equal importance to the Supply of Electricity Bill is some modification of the 1870 Tramways Act, which again was undealt with. It is, therefore, to be regretted that there has been no legislation this year which has in any way helped to improve the conditions of the electrical industry.

The past few months have witnessed considerable activity in the shape of electrical exhibitions in bringing home to the public the advances that have been made in the various applications of electricity. Keen competition in these various fields has shown the necessity for increased publicity if the present rate of progress is to be maintained, and such exhibitions as the one recently held on such an extensive and successful scale in London cannot but prove an immense stimulus to the industry generally. Seeing is believing, and the real value of exhibitions is in the educational effect that they have on the public generally, whereby the value of the various applications of electricity can be brought home more forcibly than by descriptive articles or in any other of the many ways adopted. Considering what an important centre Manchester has now become in the electrical industry, it is worth consideration whether in the near future a local exhibition might not be held with advantage to all concerned. During the last few years British manufacturers have undoubtedly made up a lot of lost ground. But a short time since it appeared that as a country we were not keeping pace with American and Continental firms, and that great enterprises were passing into the hands of competitors. Whilst admitting that low prices, brought about by over-production and industrial depression, had much to do with the placing of important works abroad, it cannot be said that British manufacturers were in such a strong position then such as they held to-day. A closer appreciation of the lines on which electrical enterprises are developing, coupled with improvement in designs and methods of manufacture, have placed manufacturers in a position fully equal to their competitors, and able to supply the demands of the country. Whilst the lessons of the past few years' experience have been for the most part turned to good account, British manufacturers have still, it is feared, to learn the meaning of "prompt delivery." It would be interesting if a return could be prepared of the large contracts made during the year and the number of those given that were completed within the specified time. Judging by results, it is apparent that only too often times and dates are given that cannot possibly be complied with, and without any serious attempt to compute the actual time required for their completion. The enforcing of penalties may have weight with the manufacturers, but it is no adequate compensation to the engineer who requires the plant, and from the latter's standpoint reliability for delivery will often weigh as much or more than lower first cost..

I have endeavoured to indicate briefly some of the advances that have been made in the various spheres of the application of electricity, and to point out some of the considerations which govern a solution of many of the problems of the day. Some of these appear considerably far off from being satisfactorily solved. Take the case of electrical storage. The development of storage is desired by all engineers, but all are not agreed that it is on the lines of the ordinary lead couple accumulator that perfection will be found. On the contrary, very strong views are entertained that something better than this method will have to be developed before electrical storage can on economic grounds be applied on anything approaching an extensive scale. We should not, however, be unmindful of the great improvements that have been made in recent years towards increasing the life of the battery, as a whole, by means of automatic "boosters," and improvements in the manufacture and formation of the plates, and a consequent reduction in the cost of upkeep. Whether in the present type of accumulator, improved as it undoubtedly may be from year to year, or in some form akin to that on which Edison has been working the final solution will be found, is a problem for the future. The recent experiments of Sir Oliver Lodge, employing high static charges for the purpose of dispelling fog from the atmospheres of our large cities and towns are worthy of note, as containing the possible fundamentals of future developments.

I do not propose to further trespass on your time. Enough has been said to show the value of electrical engineering progress to the community generally, and which has brought in its trail social changes of untold benefit to mankind. Of the electrical engineer may it not be truly said that he has been engaged "in directing the great sources of power in Nature for the use and convenience of man"? In conclusion, may I express the hope that the session on which we enter this evening may be as successful as those that are past, and that the discussions of the papers presented may be mutually helpful.

Mr. R. J. Roberts, of Merthyr Tydvil, has been appointed junior charge engineer at the borough of Cheltenham electricity works.

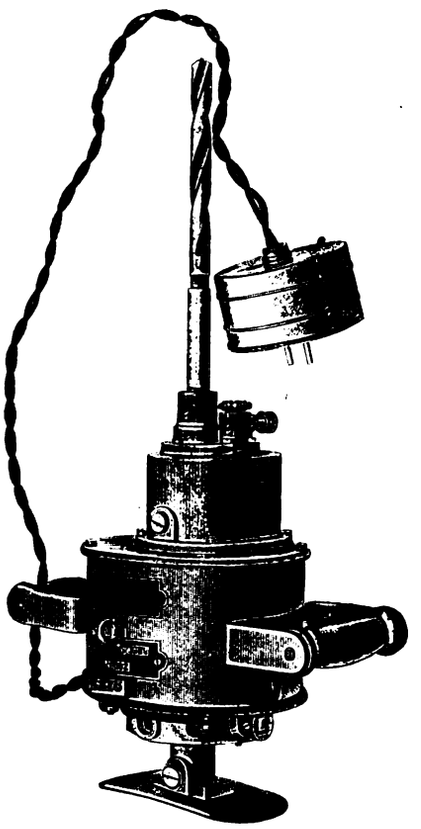
TRADE NOTICES AND NOVELTIES.

Variable-Speed Electric Drill.

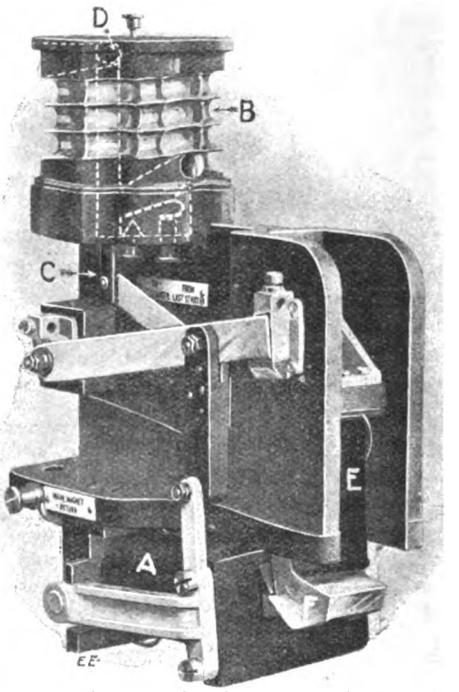
From the Armorduct Manufacturing Company, Limited, 6, Farringdon-avenue, London, E.C., we have particulars of their "Little Hustler" variable-speed electric drills for con-



tinuous and three-phase current. The accompanying illustration shows one pattern of this extremely useful type of drill, which can be adjusted to three speeds, according to the size of bore intended. The motor is shunt-wound, and gives its full power on the different speeds, the latter being obtained entirely by the agency of a special gear. There is no waste of energy. All non-magnetic parts are made of an aluminium alloy, so as to obtain lightness. A further noteworthy feature is that the plug-top attached to the flexible cord contains a maximum cut-out, which, in case of overload, stops the tool, the latter automatically restarting when the boring pressure is reduced to normal. This device makes it impossible for the motor to burn out due to overload, and renders the tool fool-proof.

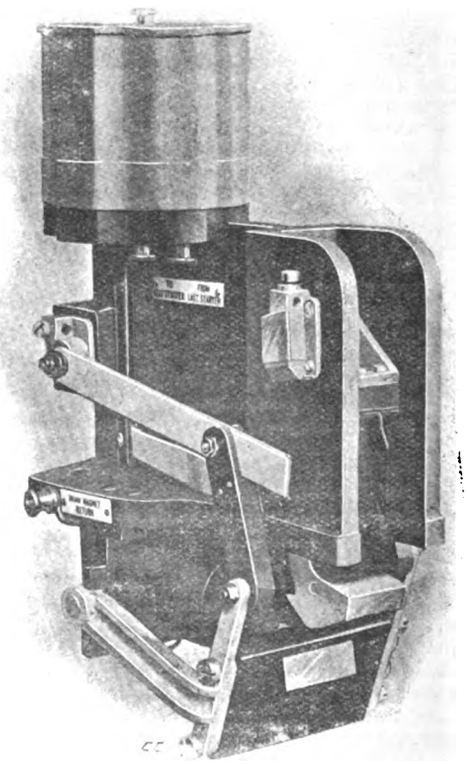
The Glasgow Arc Lamp Starter.

Many of our readers will be interested to learn that Mr. James Ferguson, late manager, electrical department, Kelvin and James White, Limited, has now started business on his own account at 61, Pollok-street, Pollokshaws, Glasgow, where he has put down modern plant for the manufacture of light electrical and mechanical apparatus generally. We are indebted to Mr. Ferguson for the following particulars of the "Glasgow" arc lamp starter (Lackie, Calderwood, and McEwen's patent), of which he is sole maker. A number of these starters have been in use, we understand, on the Glasgow Corporation street-lighting system for over eight months, giving every satisfaction. Regarding the identity of the patentees, Mr. Lackie is, of course, the chief electrical engineer to the Glasgow Corporation, while Mr. Calderwood and Mr. McEwen are well-known members of his staff. This apparatus has been designed for switching in street arc lamps with an interval of time between each group. Referring to the accompanying illustrations, it will be seen that the switch consists principally of two parts—viz. (1) a main switch proper controlled by an electromagnet; and (2) the time-element mechanism which closes a secondary circuit after a predetermined interval, thus actuating the main switch of the next switch in the series. From any central or suitable point a series of lamps may be switched into circuit, set after set of the series, with a time interval between the switching in of the various sets; on the last of the sets being switched in, contact is automatically made to indicate at the central switching point that the circuits have been completed throughout the entire series. The interval of time obtained between the lighting one set or group of arc lamps and another set or group of arc lamps permits of the electric current being steadied, to obviate flickering of the lamps of private consumers. The electromagnetic switch is actuated by a powerful electromagnet, A, rotating an armature which is pivoted by arms to the yoke. This armature is coupled by insulated connecting pieces at the sides to the double-pole switch, which is provided with suitable carbon contacts. One of the switch coupling pieces is fitted with an arm which is coupled to the plunger, C, which actuates the time-element mechanism. The whole apparatus is fitted on a base of insulating material with an insulating partition between the two switches, so that accidental contacts between



Arc Lamp Starter with cover of time element removed. The white dotted lines show the travel of the plunger and ball. One-quarter full size.

the positive and negative terminals, or between the positive or negative terminals and the middle-wire terminals, may be made difficult or impossible. The time-element mechanism consists of a wavy spiral, B, the axis of which is vertical, mounted on a



Complete Arc Lamp Starter in "Off" position. One-quarter full size.

platform forming part of the insulating base. Through the centre of both the spiral piece and the base is a hole large enough to allow a plunger, C, to pass freely up and down. The function of this plunger is to elevate a smooth spherical ball, D, from the bottom of the base to the top of the spiral. The ball then descends by travelling round the zig-zag till it reaches the base, where it rolls on to the top of the contact spring, pressing

Digitized by Google

it down against the fixed contact and closing the circuit for the relay magnet of the next starter. The time taken for the ball to travel from the top till it closes the circuit for the next switch is 11 seconds, or sufficient to allow one group of lamps to be burning steadily before the next group is switched on. When the starter is switched out, the plunger drops to the bottom and the ball rolls off the contact spring on the top of the plunger ready for the switching-in operation. A clutch, F, which can be released by the electromagnet, E, holds the switch on. As soon as the "all on" lamp in the station lights up, indicating that all the groups of lamps in the series have been switched on, the switch for the electromagnet, A, may be opened and the switches are held on mechanically. To open the switches, the main magnet or "in" switch is first closed, thus relieving the clutches, F, which are withdrawn on closing the "off" switch which controls the circuit for the electromagnet. The whole apparatus is of the most substantial construction, and has been designed for fitting in section pillars or lamp pillar bases.

Saving in Cost of Arc Street-Lighting due to the use of Arc Starters.—Wages saved by using starter, taking 850 street arc lamps: Men employed without starters—11 men at 27s. per week, 1 man at 24s. per week, 11 men at 21s. 5d. per week = £27. 16s. 7d. per week, or £1,446. 16s. 6d. per annum. Men employed with starters—16 men at 27s. per week (average), £21. 12s. per week, or £1,123. 4s. per annum. Saving per annum in favour of starters, £323. 12s. 6d.

Units Saved by Using Starters.—The switching in need not be started so early or the switching out so late as when men have to go the round of lamps. Taking the time of burning on this account as half-hour less per day, lamps taking 500 watts, or half a Board of Trade unit per hour, the units saved will be $850 \times \frac{1}{2} \times \frac{1}{2} = 212{\cdot}2$ units. At 1d. per unit this would amount to, say, 17s. 8½d. Also 12 pairs of carbons would be saved. At 1s. 3d. per dozen pairs, this would amount, together with the cost of setting and trimming them, to 2s. 3d. per day.

Therefore, total saving is 17s. 8½d. and 2s. 3d. = 19s. 11½d.—*i.e.*, £364. 4s. 9d. per annum. Total saving: men's time, £323. 12s. 6d.; current, carbons, etc., £364. 4s. 9d.—total, £687. 17s. 3d., say £688. Allowing one starter to 10 lamps at £10 each installed, taking depreciation at 7½ per cent., interest 5 per cent., and sinking fund 2½ per cent. per annum, makes £127. 10s. on £850 capital. Deducting this annual amount from £687. 17s. 3d., leaves £560. 7s. 3d. net saving on 850 arc lamps, which is equivalent to 13s. 2d. per lamp per annum.

Catalogues, etc.

"WITTON" MOTORS.—The abbreviated price-list of "Witton" continuous-current motors just being issued by the General Electric Company, Limited, will be found extremely handy for reference. It can be carried in the pocket without inconvenience.

GILBERT ARC LAMP.—From the Gilbert Arc Lamp Company, Limited, Chingford, Essex, we have a copy of their new catalogue. This is a very comprehensive list of the company's manufactures, including every type of arc lamp and accessories for same.

DRY BATTERIES.—The Amalgamated Dry Batteries, Limited, 16-17, Devonshire-square, Bishopsgate-street Without, E.C., have recently issued a new catalogue of their specialities, all of which are manufactured in London, being of the highest quality throughout.

IGNITION BATTERIES.—The Hart Accumulator Company, Limited, Marshgate-lane, Stratford, E., are issuing a new price-list of their specially-designed ignition batteries in celluloid boxes. We understand there is a very large demand for these batteries. Stock of all sizes is kept ready for immediate delivery.

FORTHCOMING EVENTS.

FRIDAY, DEC. 8.

Institution of Electrical Engineers (Manchester Local Section).—At 7.30 p.m., "Electrification of Existing Steam Railways," by Mr. W. H. M. Parr.

Northampton Institute.—At 8 p.m., Sir William Preece, K.C.B., F.R.S., delivers the prizes at the annual prize distribution and conversazione.

Institution of Electrical Engineers.—At 7 p.m., annual dinner at Hotel Cecil.

SATURDAY, DEC. 9.

Institution of Electrical Engineers.—At 10.30 a.m., students' visit to Bow Central Station.

Birmingham Electric Club.—At 7.30 p.m., annual meeting (Colonnade Hotel).

Northampton Institute.—At 6.30 p.m., annual conversazione.

MONDAY, DEC. 11.

Institution of Mechanical Engineers.—"Organisation in Small Engineering Shops," by Mr. A. W. Waddy.

Society of Arts.—At 8 p.m., "The Measurement of High-Frequency Currents and Electric Waves," by Dr. J. A. Fleming, D.Sc., F.R.S. (in continuation of previous courses on "Electric Oscillations and Electric Waves" and on "Hertzian Wave Telegraphy"). (Lecture III.)

TUESDAY, DEC. 12.

Society of Arts.—At 8 p.m., "Historical Pageants," by Mr. Louis N. Parker, F.R.A.M.

Institution of Electrical Engineers (Glasgow Local Section).—At 8 p.m., "Recent Advances in Wireless Telegraphy," by Dr. J. Erskine-Murray.

Institution of Electrical Engineers (Manchester Local Section).—At 7.30 p.m., "Street-Lighting," by Mr. Haydn Harrison.

Nottingham Guild of Mechanical and Electrical Engineers.—At 7.30 p.m., "Electric Cables," by Mr. J. Preece.

Institution of Civil Engineers.—At 8 p.m., "The Steam-Turbine," by the Hon. C. A. Parsons and Mr. G. G. Stoney.

WEDNESDAY, DEC. 13.

Society of Arts.—At 8 p.m., "The Commerce and Industries of Japan," by Mr. W. F. Mitchell.

Institution of Electrical Engineers (Birmingham Local Section).—At 7.30 p.m., "Two New Electricity Meters," by Mr. F. B. Holden.

Institution of Electrical Engineers (Students' Section).—At 7.30 p.m., "Flame Arc Lamps," by Mr. L. V. Pumphrey.

Association of Engineers-in-Charge.—At 8 p.m., "High-Pressure Gas Illumination," by Mr. J. W. Blakey.

Wolverhampton Engineering Society.—At 7.30 p.m., "The Locomotive of To-day," by Mr. G. Bulkeley.

THURSDAY, DEC. 14.

Tramways and Light Railways Association.—At 3 p.m., visit to Lots-road Power station. At 8 p.m., "Improvements in Trucks," by Mr. E. Cook.

Institution of Electrical Engineers.—At 8 p.m., adjourned discussion.

Society of Arts.—At 8 p.m., "Glimpses of French Canada," by the Hon. Rodolphe Lemieux, K.C., Solicitor-General of Canada.

FRIDAY, DEC. 15.

Electro-Harmonic Society.—At 8 p.m., smoking concert.

Institution of Civil Engineers (Students' Meeting).—At 8 p.m., "Tests of Street Illumination in Westminster," by Mr. E. E. Mann, B.Sc., Stud.Inst.C.E. Mr. E. W. Monkhouse, M.I.C.E., in the chair.

Junior Institution of Engineers.—At 8 p.m., "Electric Mains for Power Transmission Work," by Prof. John T. Morris, M.I.E.E. (member).

Physical Society.—7 to 10 p.m., Exhibition, Royal College of Science, South Kensington.

Institution of Mechanical Engineers.—The seventh report to the Alloys Research Committee, "On the Properties of a Series of Iron-Nickel Manganese-Carbon Alloys," by Dr. H. C. H. Carpenter, Mr. R. A. Hadfield (member), and Mr. Percy Longmuir; paper to be read and discussed (if time permits), "Behaviour of Materials of Construction under Pure Shear," by Mr. E. G. Izod (associate member), of Rugby.

SATURDAY DEC. 16.

Junior Institution of Engineers.—At 10 a.m., visit to Messrs. Johnson and Phillips's works at Charlton.

Institution of Electrical Engineers (Manchester Local Section). At 2 p.m., students' visit to generating station.

PERSONAL.

Mr. J. H. Ferguson, at present stationed at Falkirk, has been appointed resident electrical engineer at Lanark District Asylum (Hartwood). There were over 300 applications.

The Gloucester City Council have appointed Mr. Leonard Johnston, of Blackburn, tramways manager at a salary commencing at £250, and increasing £25 a year up to £350.

The Dover Town Council have appointed Mr. R. E. Heygate as shift engineer, at a salary of £80 per annum, in place of Mr. Irish, resigned.

The St. Marylebone Council have engaged Mr. W. E. White, of the Brighton Corporation, at a salary of £3 per week, for the purpose of dealing with consumers' accounts generally, and the work in connection with the tariff of charges to consumers.

Mr. M. M. Gillespie, until recently a prominent member of the staff of the British Westinghouse Electric and Manufacturing Co., was on Friday last entertained to a complimentary dinner given at the Midland Hotel, Manchester, by his old friends and colleagues in the firm. The proceedings, which were of the usual informal and delightful nature, bore ample witness to the popularity of a gentleman who has been associated for over 17 years with the Westinghouse companies on both sides of the Atlantic. Mr. Gillespie has opened offices at Amberley House, Norfolk-street, Strand, W.C., where he will represent, among other firms, Messrs. Browett, Lindley, and Co. for London and the South and West of England.

The employés of the British Electric Plant Co., Alloa, have presented Mr. W. L. Spence, A.M.I.C.E., M.I.M.E., on the occasion of his retiral from the managing directorship of the company, with a testi-

Digitized by Google

monial, which was subscribed to by every employé at the works. It consisted of a large combined filing and card indexing cabinet and a framed enlargement photograph of the staff and workmen. We are informed that Mr. Spence is now practising as a consulting electrical and mechanical engineer in Glasgow.

Mr. Henley L. Howard, A.M.I.M.E., A.M.I E.E., of the Manchester Corporation electricity works, has been appointed engineer and general manager to the Barking Town electricity and tramways department.

Mr. Joseph H. Bryan, of Messrs. Ferranti Limited, has been appointed meter inspector at the Croydon borough electricity works.

The following changes have been made in the staff of the Maidenhead electricity department: Mr. Aubrey Fletcher has taken up his appointment as assistant engineer from 11th inst.; Mr. J. A. Squire has left and joined Messrs. Oliver and Co., Woolwich; Mr. K. L. M. J. Schultz leaves the works next week; Mr. A. Stevens has been taken on for one month's approbation, and will then apply to the committee for permission to serve six months as a volunteer, or to be articled as an improver under the committee's usual conditions.

PORTSMOUTH ELECTRICITY ACCOUNTS.

The accounts of the Portsmouth electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £275,819. Abstracts of the revenue account, balance-sheet, etc., are appended.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
To generation of electricity	17,696	5	6
Distribution of electricity	1,176	0	9
Attending and repairs to public lamps	1,402	13	4
Rents, rates, and taxes	1,598	7	1
Management expenses, salaries, etc.	2,351	13	4
Special charges, insurances, etc.	496	10	3
Bad debts written off, etc.	95	0	2
Total expenditure	24,816	10	5

PHYSICAL SOCIETY.

At a meeting of this society on Nov. 24, Prof. J. H. Poynting, F.R.S., president, in the chair,

A paper on "*The Dielectric Strength of Air*" was read by Mr. A. Russell. The dielectric strength of air, at a given barometric pressure, is generally deduced from the results of experiments made on the disruptive voltages between equal metal electrodes at given distances apart. It is assumed that the electric field surrounding the two electrodes just before the disruptive discharge takes place is similar to that round the electrodes at low voltages. Schuster has shown that this assumption is untenable. The author has found that in certain cases the dielectric has broken down before the final discharge takes place. Hence the boundaries of the Faraday tubes are no longer the surfaces of the metal electrodes, but the boundary of that part of the dielectric surrounding the two electrodes which has ceased to insulate and has become a conductor. It is known that for various gases there are certain minimum sparking potential differences between the electrodes. The electrostatic equations fail to take this into account. The author, therefore, makes the assumption that for distances apart greater than about a millimetre when the disruptive voltage is V kilovolts the effective potential difference between the ends of the Faraday tube which is subject to the maximum stress is $V-\epsilon$, where ϵ is the minimum sparking voltage. Applying formulæ which he has deduced, using this assumption, to tests of Heydweiller, Steinmetz, Algermissen, etc., the author finds that they agree in making the dielectric strength of air 38 kilovolts per centimetre approximately. A knowledge of this quantity enables us to find not only the disruptive voltages between electrodes of many geometrical shapes, but it also enables us to find the "critical" pressure for overhead electric power transmission at high pressures. The author gives a complete proof by Kelvin's method of images of the Kirchhoff series formula, and shows how its numerical value can be readily found both by ordinary algebra and by elliptic function series.

Dr. H. A. Wilson expressed his interest in the author's explanation of the brush discharge and the formation of coronas. There were, however, one or two points in the paper which required some alteration. The author stated that according to Strutt the minimum sparking potential difference was 767 volts when the barometric pressure was 72·4cm. The pressure in Strutt's experiments was, however, 72·4mm. When the distance between the electrodes was not too small, it was known that the sparking potential difference could be expressed as $V=\alpha+\beta d$, where d was the distance between the electrodes and α and β were constants. This constant β the author had called the dielectric strength of air, but he did not think he was justified in doing so.

The Chairman, referring to Table V. in the paper, asked if the rise in value of the dielectric strength as the distance apart of the electrodes increased was due to the formation of coronas.

Mr. Russell, in reply, thanked Dr. Wilson for pointing out that in the paper the atmospheric pressures at which Mr. Strutt had obtained his results were quoted in centimetres instead of millimetres. Mr. Strutt had shown that the potential difference between the cathode and the negative glow was 341 volts whatever the atmospheric pressure. We were, therefore, quite justified in assuming that at ordinary pressures the electric pressure on the Faraday tube subject to the maximum stress is $V-\epsilon$, where ϵ is greater than 341. The experimental results analysed in the paper indicate that ϵ is 0·8 of a kilovolt. In answer to Prof. Poynting, he stated that the slight rise in the values of the dielectric strength in Table V. was probably due to the potentials of the electrodes not being V and zero at the instant of discharge.

A paper by Dr. H. A. Wilson and Mr. E. Gold, "*On the Electrical Conductivity of Flames for Rapidly Alternating Currents*," was read by Dr. Wilson. This paper contains an account of a series of experiments on the electrical conductivity of a Bunsen flame containing various alkali-salt vapours for alternating currents with frequencies from 7×10^4 to 11×10^5 alternations per second. The conductivity was measured between two platinum electrodes immersed in the flame, and the variation of the conductivity with the amount of salt present and with the nature of the salt was investigated. The variation of the conductivity with the frequency of alternation, the maximum E.M.F., and the distance between the electrodes was also examined. The results obtained enable a comparison to be made between the conductivities of various alkali-salt vapours for alternating currents and their conductivities for steady currents as previously determined. The conductivity was measured by means of a Wheatstone's bridge, three arms of which consisted of small air condensers and the fourth of the electrodes in the flame. One of the condensers could be adjusted until a balance was obtained. The following is a summary of the results: (1) For rapidly alternating currents a flame containing an alkali-salt vapour behaves like an insulating medium of high specific inductive capacity. (2) The conductivity of different alkali-salt vapours in a flame for rapidly alternating currents, as measured by the apparent capacity of platinum electrodes immersed in the flame, varies as the square root of the conductivity of the same salt vapours for steady currents. This result confirms the view that the negative ions from all salts have the same velocity. (3) The apparent capacity varies nearly inversely as the square root of the maximum applied potential difference. (4) The apparent capacity is nearly independent of the number of alternations per second. (5) The apparent capacity is nearly independent of the distance between the electrodes. (6) The results (1) to (5) are in agreement with the ionic theory of the conductivity of the flame for rapidly alternating currents when the velocity of the positive ions and the inertia and viscous resistance to the motion of the negative ions are neglected in comparison with the effects due to the number of ions per cubic centimetre. (7) The apparent capacity per square centimetre area of the electrodes is equal to $\sqrt{n\epsilon/8\pi V_0}$, where n is the number of positive ions per cubic centimetre, ϵ the charge on one ion, and V_0 the maximum applied potential difference. (8) Not more than one molecule in ten of salt molecules is ionised at any instant, but each molecule is probably ionised and recombines several million times per second. (9) The steady currents observed through salt vapours in flames are very far from the maximum possible currents corresponding to the number of ions produced per second.

Mr. W. Duddell expressed his interest in the method of measurement, and referred to the fact that, although the paper was entitled "The Electrical Conductivity of Flames," the authors had not measured conductivities but a complex quantity which was equivalent to a resistance shunted with a condenser. He drew attention to one of the tables given in the paper in which numbers referred to as constant varied by over 50 per cent.

Dr. Wilson said the quantity which they had measured was the apparent capacity of the electrodes.

LEGAL INTELLIGENCE.

ENGLISH ELECTRO-METALLURGICAL CO.

The Court of Appeal, consisting of Lords Justices Vaughan Williams, Stirling, and Ozens-Hardy, delivered a considered judgment last week in the case of the English Electro-Metallurgical Co. *v.* the Glasdir Copper Mines, Limited, on the plaintiffs' appeal from the judgment of Mr. Justice Joyce.

In this case the plaintiffs, the debenture holders of the defendant company, sought to put in force a charge created by the debentures. The debentures were a charge upon the whole undertaking of the company, and were issued subject to the condition that the charge created should be a floating security, but so that the company was not to create any charge in priority to them. In February, 1901, a receiver and manager was appointed, and subsequently in that year an order was made that he should be at liberty to borrow £500 for the purpose of preserving the property of the company, the money so borrowed to be a first charge upon the property. Liberty was given afterwards to borrow further sums. All the moneys which the receiver was authorised to borrow were advanced by the plaintiff company, and the charges which were executed were expressed to be first charges, comprised in or charged by the securities created by the debentures; but there was a provision that the receiver should not be personally liable to repay the advances out of his own pocket. Subsequently the company's lease was forfeited, and the only assets realised were certain fixtures and plant, which were sold. As there was not enough money in the hands of the receiver, after paying management and receivership expenses, to satisfy the plaintiffs' charges, they issued a summons asking the Court to direct that the receiver should be ordered personally to pay the sums advanced. Mr. Justice Joyce, however, held that the expenses of receivership and management had priority over the charges held by the plaintiffs for the sums advanced by them. Hence the present appeal.

Their Lordships held that Mr. Justice Joyce's decision was right, and dismissed the appeal, with costs.

A TRAMCAR COLLISION.

At the Kingston County Court last Tuesday, before his Honour Judge Russell (and a jury), Thomas Stamp Brewis, of Norbiton, sued the London United Tramways Co. for injury to a horse and damages to a van and load of hay, sustained in a collision in the Hampton Court-road, Hampton Wick, on Aug. 5 last.

The plaintiff's case was that the van was proceeding along Hampton Court-road at a walking pace on its proper side, but it overlapped on the tramlines. Without any warning a tramcar coming in the same direction as the van from Hampton Court ran into the tail-end of the van at such a pace that it pushed the van on some 6ft. The horse then bolted, and the unfortunate driver was thrown off and killed. The horse bolted along the road some distance, and the van was then overturned.

For the defence it was urged in mitigation that the night was so dark and the street illumination so bad that the driver could not see ahead of him.

After careful summing up by his Honour, the jury retired for five minutes, and on their return into court found a verdict for plaintiff, and assessed the damages at £30.

ACTION AGAINST THE HECKMONDWIKE DISTRICT COUNCIL.

The action of D. Stewart and Co., of Glasgow, *v* the Heckmondwike Urban District Council came on for trial last week before Mr. Pollock, K.C., official referee. The plaintiffs are boiler manufacturers, and the action was brought to recover the price of certain water-tube boilers supplied to and work done for the defendant Council in connection with a scheme for lighting the town by electricity. The real point in the case was whether the boilers which were supplied were capable of evaporating 4,000lb. of dry steam per hour under normal conditions and with average coal as specified in the contracts. Defendants said the boilers would not come up to that test, and counter-claimed for damages or set-off. A further point in issue would be as to what was meant in the contract by "normal condition and average coal." The Council's engineer claimed the right to say what were normal conditions, but plaintiffs said the amount of draught in the Council's works was abnormally low and was insufficient to burn the coal properly

Digitized by Google

Eventually the Council pulled down the boilers and erected other boilers, and the action was commenced.

After the case had been adjourned it was announced that the action had been settled out of court, each party paying their own costs.

BELFAST ELECTRIC TRAMWAYS.

In the King's Bench Division on Friday last, before the Lord Chief Justice, Mr. Justice Madden, Mr. Justice Gibson, and Mr. Justice Boyd, in the case of Eccles *v.* White and Co., Mr. M'Grath, K.C., applied on behalf of the defendants, Messrs. J. G. White and Co., contractors for the Belfast electric tramways, for an order to remit the action for trial to the Recorder at Belfast. The plaintiff, Mr. John Eccles, a commission agent residing in Jameson-street, Belfast, sought to recover damages from the defendants for personal injuries alleged to have been sustained on the night of Aug. 4 in Victoria-street through the negligence of the defendants. It appeared that the plaintiff was driving a trap when he collided with a pole erected by the defendants, which was not lighted, contrary to the terms of their contract and the by-laws of the Belfast Corporation, with the result that he was thrown out of the trap and sustained the injuries mentioned.

On behalf of the defendants it was contended that the action was one which should be properly retained in the Superior Courts.

The Court remitted the action.

COMPANIES' MEETINGS AND REPORTS

CAPE ELECTRIC TRAMWAYS.

The ninth ordinary general meeting of shareholders in the Cape Electric Tramways Co. was held on Wednesday, the 6th inst., Colonel Sir Charles Euan-Smith, chairman of the Company, presiding.

The CHAIRMAN, in moving the adoption of the report (copy of which appeared in our issue of the 24th ult.), said that, irrespective of the loss which had been incurred in the working of the Camps Bay system, the gross receipts from the working of the two systems of Cape Town and Port Elizabeth had fallen off during the year to the extent of some £17,000, a loss due, in the opinion of the Board, directly to the profound commercial depression which had reigned over the entire Cape Colony during the year under review, and which had affected all commercial enterprise in that country, and had naturally injured this Company's tramways, which were singularly sensitive to the state of the commercial atmosphere. In spite, however, of these adverse conditions, the directors had paid to the shareholders 5 per cent. on their capital, making the customary provision of £8,000 for the reserve fund. The hope expressed last year as to the early revival of prosperity had not, so far, been realised, and whilst there was no sign at present of immediate recovery, nevertheless there were symptoms that business depression had reached the worst. It was, however, his duty to inform the shareholders that since the date of the balance sheet the position had not improved, and the receipts continued to show a falling off combined with increased expenditure as compared with the same period of last year. This loss in both directions was largely due to the interruptions caused by the renewal work which was happily now nearing completion, so that they might hope in the next few months for slow and sure recovery, and, by improved service, to do better business. As to the question of dividends, it appeared to the Board opportune, in consequence of some remarks that were made at the last extraordinary general meeting called to increase the borrowing powers of the Company, to bring to the recollection of shareholders that the former large dividends and bonuses were never issued unless accompanied by a warning that it would be wrong to encourage a belief on the part of the shareholders that the Company could continue to earn and distribute so high a standard of profit and interest. It had been specially pointed out that the distributions sanctioned by the Board must necessarily be regarded as due to quite exceptional causes that might at any time cease to be operative. This was exactly what had taken place, and a period of active and promising prosperity had been succeeded by a period of profound commercial depression, which had made it impossible to earn and distribute the same dividends as formerly. The other important subject which had called forth so much criticism was the leasing of the Camps Bays tramways, which lease expires on the 31st of the present month, and this Company's connection with that line would then cease. During the past year the general renewal work of the systems was commenced, and was now nearly completed, as was also the construction of the important extension through Buitengracht-street. As practically the whole of their reserve fund had been from time to time invested in the enterprise, the money required for these renewals and extensions was obtained on loan, and the financial arrangements were completed at the extraordinary general meeting held on Oct. 25 last, whereby an issue of debentures of £200,000 was authorised. It was intended, as then announced, that £100,000 of this issue should be utilised for the repayment of the loan, and the Board would await the first favourable opportunity to negotiate the same in the market. In June last the Company was subjected to a substantial loss by a most serious gas explosion, which destroyed much of the newly completed line in Adderley-street, and, what was equally detrimental, interrupted their operations for some time in that most frequented and best section of the tramways, but the Board were, under advice, seeking remedy for this damage by legal process. Then, again, they had been subjected, both in Cape Town and Port Elizabeth, to unprecedently severe floods and violent storms, which were a great hindrance to traffic, and thus added to their many troubles. The important question of the compensation to be paid by Government for the expropriation of the Company's valuable property, the Sea Point Railway, was now *sub judice*, and therefore it would not be advisable to dwell upon it at that meeting. Whilst the Board had felt it their duty to lay before the shareholders an exposition of the various causes which had operated disadvantageously to the interests of the Company, they still bore in mind the brighter circumstances that might be found in the future. The recuperative power of Cape Colony was well known, and must be aided by the increasing gold production of the Transvaal. The abundant rains which had fallen throughout the greater part of Cape Colony also gave promise of good crops and improved agricultural conditions, and these must have, in due course, a favourable influence on commerce generally. Their new manager, Mr. Alfred S. Giles, had proved himself capable and energetic, and Mr. James A. Barkley, the manager at Port Elizabeth, had succeeded in lowering the operation expenses during the past 12 months without in any way sacrificing the efficiency of the service. He concluded by moving the adoption of the report and accounts.

Mr. SYDNEY MENDELSSOHN said that he had only recently returned from the Cape, and while he was there he took the opportunity of investigating the position of the tramways, and he found that the causes of the diminution in revenue were three in number—firstly, the enormous depression of business at Cape Town; secondly, the loss upon the lease of the Camps Bay line; and, thirdly, the tramlines had, in course of time, depreciated, and had to be relaid.

After some further discussion the report and accounts were unanimously adopted, the directors re-elected, and £500 voted to them as remuneration, and the proceedings terminated.

CARGO FLEET IRON.

The annual meeting was held last week at Newcastle on-Tyne.

Sir CHRISTOPHER FURNESS, M.P., presided, and in moving the adoption of the report, alluded to the purchase of the concern by the Weardale Steel, Coal, and Coke Co. The works had been reconstructed with subsidiary plant for dealing with by-products, and the comparatively small property which the Weardale occupied had become a vast undertaking. He also referred to the investments in the South Durham Iron and Steel Co., and to the policy which induced the directors to acquire a controlling interest in its affairs to avoid a situation of hostility involving fierce competition between the two concerns. The union of interests between the Cargo Fleet Co. and the South Durham Co. gave both the benefit of a union with the Weardale Steel, Coal, and Coke Co. They were not to regard the profits of the past nine months as being any criterion of future profits; he asked them to guard against expecting that, one year with another, the works would yield more than a fair remuneration for the capital they had adventured in it. The steel and iron trades were notoriously subject to fluctuations. In bad times like those through which they had been recently passing, they were apt to think they should never win through; in good times they were apt to spend as though they would never come to an end. The policy he invariably recommended for every concern in which he was interested was to build up a sound reserve as a bulwark against bad times.

The report was adopted.

SOUTH DURHAM STEEL AND IRON.

The annual meeting was held last week at Newcastle-on-Tyne, Sir Christopher Furness, M.P., presiding.

The CHAIRMAN, in moving the adoption of the report, said the expectations held out at the last annual meeting had been amply fulfilled, the profits of the nine months having been £109,123, against £80,095 for the previous 12 months. They had continued to enlarge their production and reduce their costs by judicious capital expenditure, but they could not have reached such a high total if they had not been able to take full advantage of the steel produced by the associated company, the Cargo Fleet Co., all of which they had rolled in their mills to the mutual advantage of both concerns. The steel trade was notoriously one of many fluctuations, and it had been remarked that in the industry "one must be either a prince or a pauper." He thought they had gone through the pauper period, and, judging by the order-book, it looked as though they were about to experience a fair measure of prosperity.

The report was adopted.

TUBES LIMITED.

Mr. ARTHUR CHAMBERLAIN presided at the annual meeting of Tubes Limited, at Birmingham, last Friday, and, in moving the adoption of the report, he said the balance-sheet showed a loss of £12,000 in the place of a profit of £5,000 for each of the two previous years, or a difference to the bad of £17,000. For the past three years, he said, prices had steadily fallen. In 1902 their total prices fell 20 per cent. below 1901, in 1903 they fell 10 per cent. over 1902, and in 1904 they fell again 20 per cent. more than in 1903. Last year, on the top of all that, they fell 25 per cent., making a total fall of 55 per cent. in four years, and without any corresponding fall in material. There were not many businesses which could support such a fall as that and still be alive.

GENEVA TRAMWAYS.

The report of this Company for the year ended Sept. 30, 1905, to be submitted at the meeting on the 15th instant, states that the profit and loss account of the Swiss company shows a gross profit on working of £18,791, and including the credit balance of £2,855. 12s. brought

Digitized by Google

forward from the previous period, makes a total of £21,046. 12s., and after making provision for the necessary contributions to amortisation, renewal, and reserve funds, and for sundry expenses, there remained a balance of £14,504. 15s., out of which a dividend of 1 per cent., amounting to £8,000, has since been paid, leaving a balance of £6,504. 15s. to be carried forward. Additional rolling-stock having become necessary, this balance, together with a further amount from the current year's earnings, has been set aside for this purpose, which will absorb a sum not exceeding £10,000. Of the authorised issue of £20,000 prior debentures £4,000 have been subscribed and issued and subsequently redeemed in accordance with the terms of the supplementary trust deed of Aug. 26, 1903. Consequent upon the continued inability of the Compagnie Genevoise des Tramways Electriques to pay adequate dividends on its capital with which to meet this company's indebtedness, the revenue account of this company shows a loss for the period of £34,270, increasing the amount standing to debit of revenue account to £151,559, mainly the result of the accumulation of unpaid interest on the debenture issues. The directors have every reason to be thoroughly satisfied with the assistance received at the hands of the directors of the Swiss company and also with the services rendered by the general manager and staff.

ARON ELECTRICITY METER CO.

The profit and loss account for the year to Sept. 30 last, after providing for general charges, depreciation, and share of expenses and discount on the issue of debentures, shows a net profit of £11,724, making, with the balance of £412 carried forward last year, a total available profit of £12,136. Of this amount there will be set aside for the debenture sinking fund, in accordance with the trust deed, £2,500. Out of the balance of £9,636 the directors propose to pay 4½ per cent. on account of the preference dividend in arrear, absorbing £5,620, and to carry forward £4,016. The directors consider this result most encouraging. Trade in Germany and Austria has been very healthy throughout the year. The factories in Schweidnitz and Charlottenburg are also giving every satisfaction. The business in France and England is still in a somewhat unsettled condition. The outlook is, however, distinctly hopeful, and the directors will continue their policy of economy and care.

WELDLESS STEEL TUBE.

The report of this Company for the year ended Sept. 30, 1905, states that the result of the year's trading, after writing off £3 767 for depreciation, and charging all repairs and maintenance of property, plant, etc., and deducting managing directors' salaries and directors' and trustees' remuneration, is a loss of £3,845, which, deducted from the balance from the last account of £8 888, leaves a surplus of £5,042. From this there has to be deducted debenture interest for the year £1,282, preference dividend at the rate of 5½ per cent., leaving a balance of £1,670, which the directors recommend shou'd be carried forward.

BULLERS LIMITED.

The report of this Company for the year ended July 31, 1905, states that the trading accounts, after paying directors' fees and managing directors' salaries, show a profit of £35,588, which, with £781 brought forward, makes a total of £36,369. The directors propose to pay a further 2½ per cent. on the ordinary shares, making 10 per cent., to place £5,000 to reserve, which will then amount to £50,000, and to pay a bonus of 5 per cent. on the ordinary shares, carrying forward the balance, £1,369.

NEW COMPANIES REGISTERED.

Crawford Electric Lamp Syndicate, Limited. — Capital, £30,000. Object: to carry on the business of manufacturers, sellers, and suppliers of electric lamps, suppliers of electricity, etc.

H. E. Steel Limited.—Capital, £10,000. Object: to carry on the business of electrical, automobile, and general engineers, manufacturers of automobiles, omnibuses, and public carriages, etc. Registered office: 27, Regent-street, Cheltenham.

Automatic Electric Block Signalling Co, Limited.—Capital, £1,000. Object: to adopt an agreement with the Electric Railway Signalling Syndicate, Limited, to acquire any patents and inventions, and to carry on the business of electricians, suppliers of electricity and electrical installations and machinery for light, signalling, heat, motive power, and other purposes. Registered office: 302, Finsbury-pavement, E.C.

Chilian and Bolivian Railway Construction Co., Limited.—Capital, £202,500. Object: to purchase or otherwise obtain concessions, contracts, rights, and privileges for the construction, equipment, improvement, administration, or control of railways in the Republic of Chili and Bolivia, or elsewhere in South America, or any other part of the world; to construct, equip, and work railways, tramways, etc.

Liens Registered.

Marconi International Marine Communication Company, Limited, London, E.C.—Lien registered Nov. 21, for £8,000 7 per cent. debentures part of £25,000 authorised. No trustees. Charged on the undertaking and all the property and assets, present and future including the uncalled capital for the time being.

Standard Rubber Company, Limited, Manchester.—£250 debentures, created and dated Nov. 9, 1905, charged on the company's undertaking and property, present and future, including uncalled capital, have been registered. Holder: F. H. Barker, Ashenhurst House, Todmorden. No trustees.

Bolckow, Vaughan, and Co., Limited, Middlesbrough-on-Tees.—Lien registered Nov. 25 for £32,000 4 per cent. debentures, part of £1,000,000. Amount previously issued, £261,600. No trustees. Charged on all the property, present and future, the undertaking, and business.

APPOINTMENTS VACANT.

Electrical Engineer, Radcliffe Urban District Council. Salary, £150 to £172 per annum.

Improver. Wages. 10s. per week. Applications to Box 702, *Electrical Engineer* Office.

Wireman for electric light and power plant. Applications to Box 29, *Electrical Engineer* Office.

Representatives for an electrical contracting firm. Applications to Box G 33, *Electrical Engineer* Office.

Laboratory and Workshop Assistant, Battersea Polytechnic, S.W. Commencing salary, 20s. a week.

Switchboard Attendant. Wages, 25s. per week. Applications to Box R P 5 *Electrical Engineer* Office.

Assistant Lecturer and Demonstrator in Electrical Engineering, Leeds University. Salary, £175 a year.

Representative, South Wales district, for the sale of direct and alternating motors. Apply, Box F. Z., *Electrical Engineer* Office.

Shift Engineer, London station. Salary to commence, £2 per week. Applications to Box 574, Sell's Advertising Offices, London, E.C.

Electrical Engineer, colliery in the North of England. Applications to Box Q 11, *Electrical Engineer* Office.

Junior Charge Engineer. Salary, 30s. per week, rising to 35s. Applications to the Borough Electrical Engineer, 335, High-street, Cheltenham.

Telegraph Inspector, Malay States. Salary, £225 per annum. Applications to the Crown Agents for the Colonies, Whitehall, S.W., by Dec. 12.

Electrical Mechanician, Malay States. Salary, £225 per annum. Applications to the Crown Agents for the Colonies, Whitehall, S.W., by Dec. 12.

NEW COMMITTEES.

LOUGHBOROUGH.—*Gas and Electricity*—Alderman Bumpus chairman, and Councillor Wootton vice-chairman.

MAIDENHEAD —*Electric Lighting* —Councillor Good, chairman.

MIDDLESBROUGH.—*Electric Lighting*—Councillor Charles Dorman, chairman.

STEPNEY.—*Electric Lighting* — Aldermen Barker, Brady, and Kearsey; Councillors Algar, Berringer, Gordon, Gould, Kay, Masters, O'Brien, Stettauer, and Vinall.

WARRINGTON.—*Electricity and Tramways*—Alderman Smethurst chairman, Councillor Wilkinson deputy-chairman.

WIGAN.—*Electric Light and Tramways*—Alderman Robert Layland (chairman), Alderman R. Johnson (vice-chairman), the Mayor, T. Ashton, R. Bannister, J. Cheetham, J. Gaskell, J. T. Gee, A. S. Hilton, W. Johnson, J. McQuaid, J. O'Donahue, J. Partington, R. Richards, and M. Segrave.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Swindon.—The Electricity and Tramways Department require tenders for three double-deck cars. Tenders by Dec. 19.

Heckmondwike.—Tenders are required for an installation for water purification at the electricity works. Tenders by Dec. 14.

London, W.—Messrs. Grice and Co., Addison Wharf, Warwick-road, Kensington, require a 10-ton electric derrick crane with 60ft. to 70ft. jib, continuous current.

Yarmouth.—Tenders are to be invited by the Port and Haven Commission for an electrically-driven crane. Including foundations, etc., the cost is estimated at £2,000.

Grimsby.—The Corporation require tenders for contracts contained in Specifications No. 35 39 and 43-45, for electrical plant, cables, and buildings. Tenders by Jan. 5, 1906.

Omnibus Lighting.—A London motor omnibus company is open to receive proposals for the lighting of its vehicles by acetylene or electricity. Apply to Box 306, Willing's, 125, Strand, W.C.

Sao Luiz.—The Municipality require tenders for electric lighting of the town. Tenders by Dec. 16. Particulars may be obtained from the Municipal Secretary of Sao Luiz in the State of Maranhao, Brazil.

Manchester.—Tenders are required for transformers and switchboards. Specifications may be obtained on payment of £1. 1s. (returnable) from the electricity department of the Corporation. Tenders by Dec. 19.

Digitized by Google

Launceston (Tasmania).—Tenders are invited for the supply of 500 or more electric meters and for maximum demand indicators. Tenders to Mr. C. W. Rocher, town clerk, Town Hall, Launceston, Tasmania, by 12 noon on Jan. 15.

Sofia (Bulgaria).—Tenders are invited for the electric lighting of the Government Cadet School. Tenders by Jan. 19. Offers must be addressed in the Bulgarian language and be accompanied by a deposit of 5 per cent. of the amount of the tender.

Derby.—The Tramways Committee invite tenders for the supply and delivery of materials and construction of works in connection with the conversion of existing single line into double line from Deadman's-lane to Navigation Bridge. Tenders to the Town Clerk by 9 a.m. on Dec. 19.

Spain.—The *Gaceta de Madrid* contains a notice inviting tenders, which will be opened at noon on Jan. 30 at the Directorate-General of Public Works, Madrid, for the concession of an electric tramway between Santander and Astillero. A deposit of about £208 is required to qualify any tender.

Castlerea.—The Rural District Council invite tenders for the construction of works for lighting the town of Ballaghaderreen: (1) builders' work; (2) hydraulic turbine plant; (3) electrical work. Specifications and particulars may be had from Mr. C. Mulvany, M.I.C.E., Engineer's Office, Athlone, on payment of £1 as a deposit, returnable after receipt of bona fide tender. Tenders by Dec. 23.

Poplar.—The Guardians invite tenders for the supply and erection of the following plant at the children's homes and schools now in course of erection at Hutton, Essex: (Section X) steam-engines, dynamos, pipework, etc.; (Y, part 1) main switchboard, wiring, motors, etc.; (Y, part 2) fire alarms, telephones, and electric bells. Tenders to Mr. G. Herbert Lough, clerk, Guardians' Offices, 45, Upper North-street, Poplar, E., by 6 p.m. on Dec. 13.

Spain.—The *Gaceta de Madrid* of Oct. 10 contains details of a concession for the construction of an electric tramway as an extension to that of the east of Madrid. Tenders must be sent in by Dec. 13 to the Director of Public Works, Madrid, in whose office particulars may be seen. A deposit of 1,899·95 pesetas, or about £60, is required to qualify any tender. Local representation is necessary. The same journal of Oct. 12 contains a notice of a concession granted to the Sociedad Los Tranvias de Zaragoza for the construction of an electric motor tramway in that city. The *Gacetas* may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C.

Madrid.—The Directorate-General of Public Works, Madrid, require tenders for the concession of an electric tramway between Zumárraga and Azcoitia, in the province of Guipúzcoa. An application for this concession has already been made by Don Dionisio Sorseta, who, at the same rates, will enjoy certain preferential rights over other tenderers. The competition will turn, in the first place, on a reduction of the tariffs proposed, and if two or more identical propositions are made, a further competition will take place verbally as to any reduction tenderers may be prepared to accept of the period (60 years) of the concession. A deposit of 6,897 pesetas (about £208) is required to qualify any tender.

Australian Commonwealth.—Tenders are invited by the Deputy Postmaster-General, Brisbane, for the supply and delivery at the Departmental Stores, Brisbane, of insulators, phosphor-bronze wire, copper sleeves, binders, and tapes. Tender forms, specifications, and conditions may be obtained from, and samples seen at, the Stores Branches, Postmaster-General's Department, Sydney, Melbourne, Adelaide, and Brisbane. Tenders by noon on Dec. 18.—Separate tenders are required by the Deputy Postmaster-General, Melbourne, for the supply and delivery at Melbourne of (1) 10 miles of 26-pair lead-covered paper-insulated telephone cable; (2) 1 mile of 156-pair lead-covered paper-insulated telephone cable (12½lb. conductors); (3) 5,000 barrel insulators delivery within three months of date of acceptance of tender. Tender forms, specifications, etc., and sample of insulator, may be seen at the General Post Offices, Melbourne, Sydney, Brisbane, Adelaide, Perth, and Hobart. Tenders must be endorsed "Tender for ——," as the case may be, and addressed to the Deputy Postmaster-General, Melbourne. They may be deposited in the tender-box at the General Post Office, Melbourne, or, if sent by post, must be prepaid and registered. Tenders by Dec. 17.

RESULTS OF TENDERS.

Warrington.—The tender of W. Rouse and Son, of Heckmondwike, at £279. 18s. 6d., for four car top covers, has been accepted.

North-Eastern Railway Co.—The above company have placed an order with the Brush Electrical Co., Loughborough, for 200 patent truck frames.

Bridlington.—The Council have authorised the acceptance of a tender, amounting to £1,475, for the carrying out of the electricity extension works.

Salford.—The amount of the fibre conduit order obtained by the Key Engineering Co. noted in our last issue should read 13,000 yards, and not 6,000 yards.

Torquay.—The Town Council have accepted the following tenders: Siemens Bros. and Co., engine and generator, reversible booster, motor-generator, switchgear, and connections, £5,168. 15s.; Tudor Accumulator Co., battery of accumulators, £1,966.

Whitchurch (near Cardiff).—The Asylums Committee of the Corporation have accepted the following tenders: Electrical Power Storage Co., batteries £958; Siemens Bros. and Co., engines and generators, £11,998; General Electric Co., switchboard, £627.

Beckenham.—The Urban District Council have accepted the following tenders: General Electric Co., engines and dynamos, £1,256; Mirrlees and Watson, condensers, £1,402; Elliott Bros., switchboard, £545; Brush Electrical Engineering Co.'s amended tender for machinery; and Babcock and Wilcox, boilers £3,375, pipework £1,750.

Fulham.—It is recommended that 100 meters be obtained from the General Electric Co. as follows: 70 5-ampere, at £1. 17s. 6d. each; 30 10-ampere, at £1. 19s. 6d. each. It is also recommended that the tender of Messrs. Spittle, at £299, be accepted for the electric light fittings for the town hall extension in accordance with the designs prepared by the borough surveyor.

London, S.E.—The London County Council have received the following tenders for the proposed construction of tramway lines over Vauxhall Bridge and the reconstruction of lines in Vauxhall Bridge-road:

J. Mowlem and Co.*	£4,995	0	0
J. G. White and Co.	5,200	12	7
Dick, Kerr, and Co.	5,543	16	7
C. Wall	6,520	0	0

* Recommended for acceptance.

Switchgear, etc.—Messrs. Cowans Limited, Springfield-lane, Salford, have recently received the following orders: Admiralty—main switchgear for dynamos and circuits for H.M. ships "Britannia," "Hibernia," "Warrior," "Africa," and "Cressy," and main switchgear for new battleship "Dreadnought" (the reverse-current devices for this contract are to be Andrews' patent Manchester type direct-acting circuit breakers); Greenock—feeder switchboard; Great Western Railway (per Electric Construction Co.)—13 sets alternating-current Andrews' discriminating apparatus; Bournemouth—equipment of three additional alternating-current generators with Andrews' patent discriminating cut-outs of the inductive balance type previously supplied.

St. Marylebone.—The Electric Supply Committee recommend the acceptance of the tender of the British Thomson-Houston Co., at £135 10s., for two spare armatures for the motors driving the induced-draught fans at the generating station; and the tender of Babcock and Wilcox, at £850, to put in the foundations for two boilers, superheaters, and economiser at the generating station to form a future extension of the boiler plant. The same committee have received the following tenders for a milking booster and switchboard at the generating station:

Phœnix Dynamo Manufacturing Co., Bradford*	£82
Electromotors, Limited, Manchester	98
Siemens Bros. and Co., London	103

* Recommended for acceptance.

India.—Messrs. Walter Locke and Co., of Calcutta, have been entrusted with the work of installing electric lights and fans in the Calcutta Medical College. The same firm is also busy with the electric installation in the new offices of the South British Insurance Co., the Russo-Chinese Bank, and Department of Commerce and Industry, also Messrs. Martin and Co.'s new offices in Clive-street, and St. Stephen's Church and parsonage, Kidderpore. The tenders for the Mussoorie electricity undertaking numbered 20 in all. The Brush Co.'s tender was the lowest, and the Municipal Board recommended to Government that it be accepted. Messrs. James Simpson were the lowest for pipes, and their tender was accepted. The electric tenders are, however, still under consideration. The Government Sanitary Engineer, U.P., has taken them all to Calcutta to consult with the electrical expert to the Government of India before a final decision is arrived at. The issue is exciting much interest among electrical firms.—*Indian Engineering.*

Shoreditch.—The Borough Council have received the following tenders for the extension of plant at their Whiston-street generating station:

Contract No. 34.—Three water-tube boilers, superheater, etc.			
Stirling Boiler Co. (accepted)	£6,605	0	0
Babcock and Wilcox	7,150	0	0
J. Fraser and Son (not according to specification)	7,478	0	0
Ditto	9,873	0	0
Contract No. 35.—Steam and water pipes, valves, etc.			
Stirling Boiler Co. (accepted)	1,175	0	0
E. Le Bas and Co.	1,176	0	0
Aiton and Co.	1,375	0	0
Babcock and Wilcox	1,395	0	0
J. Spencer	1,407	10	0
J. Wilson and Co.	1,472	0	0
Bennett, Sons, and Shears	2,050	0	0
Contract No. 36.—Wrought-steel flue.			
J. Fraser and Son (not according to specification)	326	0	0
Ditto (accepted)	531	0	0
Babcock and Wilcox	750	0	0
Fraser and Fraser	786	0	0
Meehan and Co.	796	0	0
Pierson and Co.	810	0	0
Stirling Boiler Co.	872	0	0
Westwood and Wrights	875	0	0

North Metropolitan Electric Tramways, Limited.—The official opening of the electric tramway service through Alexandra Park on Wednesday marks the conjunction with the London County Council tramways to within a few feet of the Crystal Palace. Sir Francis Cory-Wright started the new service at Turnpike-lane, and within a few minutes the first car, containing the directors of the Metropolitan Electric Tramways, Limited, drew up at the terminus. The cars are of somewhat novel design. In addition to there being no seating accommodation on the outside, a patent trolley arm makes it possible to negotiate very low bridges that with the older type of trolley would be impossible.

Digitized by Google

BUSINESS NOTES.

TRACTION.

Hythe.—It is stated that motor 'buses will run between Hythe and Folkestone at an early date.

Colombo.—The relaying of the tramways on the Thermit system will be taken in hand shortly.

Birkenhead.—The Town Council have agreed to grant licenses to the Mersey Railway Co. to run four motor 'buses in the town.

Brighton.—A service of motor 'buses has been established between Worthing and Hove, and it is hoped to extend the service to Brighton.

Ilkeston.—At the last meeting of the Town Council objections were made against the running of trams on Sundays, but the mayor ruled discussion out of order.

Saint-Pierre (France).—An inquiry has been held into the proposal of the Finistère Tramway Co. to extend their line of electric tramways from Conquet to Brest.

New Issue.—The British Columbia Electric Railway Co. are offering for public subscription an issue of 185,000 5 per cent. cumulative perpetual preference shares of £1 each at £1. 0s. 10d. per share.

Beckenham.—The Urban District Council have approved a committee's recommendation that the draft agreement with the British Electric Traction Co. for the supply of current for the Penge tramways be adopted.

Aston.—The Public Works Committee reported to the Council that progress was being made with the reconstruction of the tramways, and that, with favourable weather, the trams would be running on Monday week.

Wigan.—The Electric Light and Tramways Committee have refused the application of the Ashton-in-Makerfield Urban District Council for a reduction of fares between Aston and Wigan and Bryn Station or Rose Hill to Wigan.

Portsmouth.—Arrangements are now in progress for the acquisition by the Corporation of the light railway that runs over Portsdown Hill. An extension of the tramway system to more of the suburbs of Southsea is also in contemplation.

Leyton.—The town clerk has forwarded to each member of the Council a print of the Tramway Order 5 Edward VII., Tramways Orders Confirmation (No. 2) Act, 1905, which received the Royal assent on Aug. 11, 1905. The report was received.

Eastbourne.—With a view of rendering the motor 'bus service more available for holiday traffic, the cars are to be run on special occasions to the summit of Beachy Head, *via* the Duke's Drive, as well as to Hampden Park. The service is now proceeding very smoothly, and is much appreciated both by visitors and residents.

Keynsham.—At a meeting of the District Council a letter was read from the Bath Electric Tramways Co. informing the Council that they intended to make an application to the Light Railway Commissioners for an order to authorise the construction of light railways in Somerset. It was decided by the Council to formally oppose the extension.

Lewisham.—The Works and Highways Committee of the Borough Council recommend that, subject to the Finance Committee submitting the necessary estimate of expenditure, the borough surveyor be authorised to place No. 4 burners in all the lamps along the route of tramways from Rushey-green to Loampit-hill at a cost of £60. 16s. per annum.

Leeds.—The Council had before them at their meeting on the 6th inst. a motion that the Tramways Committee be instructed to issue transfer tickets to workpeople travelling by workmen's cars when they require to transfer from one section to another, so as to enable the ticketholder to travel at least two miles for 1d. The matter was referred to the Tramways Committee.

North-Eastern Railway Co.—The company have decided to introduce a service of autocars on the railway between Newbiggin, Morpeth, and Blyth. The service will commence with the New Year, and the following additional trains will be tried experimentally: Morpeth to Newbiggin, 9; Newbiggin to Morpeth, 8; Morpeth to Blyth, 4 (Saturdays, 5); Blyth to Morpeth, 5; Newbiggin to Blyth, 5; and Blyth to Newbiggin, 5.

St. Marylebone.—It was moved at yesterday's meeting of the Borough Council that the London County Council be informed that the Borough Council of St. Marylebone are prepared to sanction the construction of a tramway along Edgware-road on the condition that one-third of the cost of widening be paid by the boroughs of Paddington and Hampstead, one-third be charged to the improvement and one-third to the tramway account.

Edinburgh.—For some time past the tramway company have been experimenting with an improved system of lighting for their cars. After exhaustive trials the directors have decided in favour of the acetylene lamps, which have been in use on the Abbeyhill and Morningside route. The lamps, which are pendant from the roof, give a bright light, well diffused over the car. The directors have entered into a contract for fitting up 100 cars in the meantime.

Greenock.—Decision has been given by Sheriff Neish in an action by Michael M'Gowan against the Greenock and Port Glasgow Tramway Co. for £100 damages in consequence of injuries received. The sheriff finds that pursuer was pushed off the car by the guard, but that the latter was not acting within the scope of his employment in pushing the man, therefore his lordship finds that the defenders are not liable to the pursuer in damages, and awards the defenders expenses.

Luton.—The trial trip of the motor omnibuses in connection with the suggested Herts and Beds service took place last week. The promoters of the scheme for connecting Luton with Dunstable and St. Albans by motor 'bus explained details before the Luton Chamber of Commerce. It was pointed out that the promoters did not wish to run counter to the Corporation of Luton. The meeting was of the opinion that the Council should be left alone to consider the tramway scheme.

Cowdenbeath.—The plans of the proposed tramways have been submitted to the Town Council, and now lie in the burgh office for public inspection. The Council find the plans do not show a double line through the burgh, and therefore they mean to appeal to the company in connection with the laying of two lines of rails. Sidings are marked to be laid down at the Bleachfield, Broad-street level crossing, High-street crossing, Toulford Arms, and Parker's-buildings, North-road.

West Yorkshire Tramways Scheme.—Parliament will be asked in the forthcoming session to sanction a scheme under which a company will be incorporated and granted power to construct and use various tramways and tramroads in the parish of Huddersfield, in the county borough of Huddersfield, the parish of Rastrick, in the borough of Brighouse, and the parishes and urban districts of Elland, Greetland, and Hipperholme, and in the parishes of Fixby and Clifton, in the rural district of Halifax.

Newcastle-on-Tyne.—At the Council meeting on Wednesday, the Mayor, in reply to an enquiry, stated that there were 102 cars on the streets and that overcrowding had been reduced. The idea of reducing fares on some routes could not be entertained. The Council agreed to authorise the construction of a double line of tramway along the new extension of Market-street from Pilgrim-street to New Bridge-street. This was to commence by a junction with the existing tramways in Market-street, and to terminate by a junction with the existing tramways in New Bridge-street.

Stepney.—The Town Council are in sympathy with the resolution passed at the Lewisham town's meeting, hoping the London County Council will speedily introduce a Bill authorising the passage of tramways over the bridges. The town clerk has been instructed to serve a notice upon the North Metropolitan Tramways Co. informing the company that unless the repairs necessary to the tramway margins, breasts, and rails in several streets in the borough are proceeded with at once, the Council will forthwith carry out the work and charge the company with the expenses incurred in so doing.

Camberwell.—The Finance Committee of the Borough Council recommend that the London County Council be asked to agree to charge the Council the rate of interest at present charged on loans for the Denmark-hill to Lordship-lane improvements until the period when the actual cost may be obtained, and when the total amount required from the Council may be taken up by deed. The recommendation arises out of the London County Council's request for payment of £2,533 and £23 by way of contribution towards the cost and expenses incurred by it in carrying out the Denmark-hill to Lordship-lane improvement, these amounts being one-third of the cost which the Council agreed to contribute.

Dewsbury-Batley.—The new tramway service on Bradford-road has now been in existence a week, and has been greatly appreciated. Experiments have been made with a view to preparing a time-table, and this will be done when the results have been tabulated and analysed this week. New one-decker regenerative cars have been tried on the Hick-lane and Thorncliffe-road lines, but it has not yet been decided where they will be permanently established. There are 14 cars on the Bradford-road lines, and the average speed has so far been 8¾ miles per hour. The speed could be accelerated if there were fixed stopping places, but there is no disposition at present to change the old system of "stop when required."

Wallsend.—The Town Council have adopted a motion calling upon the Newcastle Corporation to carry out its promise of a through service. The Council was induced to support Newcastle's plea for a tramline through Walker by the riverside on the understanding that they would run a through service to Wallsend. Newcastle now pleaded that the engineering difficulties at Fisher-hill could not be overcome. It was pointed out, however, that Newcastle had land to the south of Fisher-hill which would provide an alternative route. Meanwhile the people of Wallsend were suffering great inconvenience. It was further agreed to call on the Tyneside Co. to proceed with a promised extension to run a regular service on Neptune-road, and to provide more workmen's cars.

Wallasey.—The opening of a splendidly-equipped club to be used for social and athletic purposes by the Council's employés in the tramways and electricity department was celebrated last Monday evening by the holding of a most successful smoking concert, at which about 100 were present. The function took place at the commodious club premises, which are tastefully furnished. There is also fitted a fine billiard table, a piano, gymnasium apparatus, etc., whilst papers and periodicals are to be provided for the edification of the members. The tramway employés are to be congratulated on the acquisition of such well furnished premises, and it is to be trusted that the club will be well supported. The opening ceremony was performed by Dr. Napier, chairman of the Tramways Committee, who was supported by a number of councillors.

Elland.—Particulars of the proposed tramway scheme of the National Electric Construction Co. to link Halifax with Huddersfield, *via* Elland, were laid before the Council on the 6th inst. The intended route from West Vale to Elland would be *via* Long-wall, Jepson-lane, Victoria-road, South-gate, Dewsbury-road into Rastrick. Assurances had been given that any necessary widenings of streets or roads for trams would be done at the cost of the undertakers, also that the line from West Vale to Elland would be completed in six months from the date of the Act and the whole scheme within three years. The promoters of the scheme promise to take electric energy for the tramways from the Elland Council if it could be supplied by them at

Digitized by Google

cheaply as by other people. The company intend to ask for 42 years' possession, instead of 21 years as provided by the Act of 1870.

London.—The Special Committee of the Court of Common Council submitted a report at the last meeting on a letter from the London County Council relative to a proposal, in view of [the approaching completion of the Tower Bridge northern approach, to construct a tramway along the new thoroughfare, from the existing lines in Aldgate, *via* Mansell-street and the new thoroughfare, to near Little Tower-hill; and asking whether the Corporation would be prepared to assent to the proposal, which had been included in a draft Bill seeking parliamentary authority for new lines. The committee stated that, while fully appreciating the spirit in which the London County Council had approached the Corporation on the subject, they were of opinion that, as the consideration of the proposal in question would be affected by any discussion which might take place in Parliament on the Bill as a whole, the present was not an opportune time for the Corporation to express an opinion on such a proposal. The report was adopted.

Christiania.—The *Elektroteknisk Tidsskrift* announces that an electric railway will shortly be constructed between Christiania (Norway) and Sandviken. It is to be a double track-railway of 1·435m. gauge, the central lines of the tracks being 4m. distant and the rails 29·76 kg in weight. The maximum gradient is 1 : 50, and the minimum radius of curves is 200m. The railway is to be constructed as a standard railway. Motorcars having a speed of 60 km. and more per hour are to be used. The journey from Christiania to Sandviken is to be completed in 21½ minutes, corresponding to an average speed of 37½ km. per hour, inclusive of stoppages. One hundred and twelve trains, 56 in either direction, are to be run each day. Electrical energy is to be supplied to the railway either from a special power station near Hovik or Lysaker or else from the municipal electricity works. The cost of construction of the railway is estimated at 1,770,065 kr., inclusive of the cost of purchasing the ground, as well as the rolling material, line, and electric plant.

Guildford.—It is reported that the directors of the West Surrey Light Railway Co., who are the promoters of schemes for the provision of electric tramways between Guildford and Stoughton, and for similar tramways at Woking, in addition to a projected light railway between Woking and Bagshot, will make an early start with the project. Arrangements have been made with the firm of Messrs. Johnson and Phillips for the execution of the work. Under the order the period within which the tramways must be completed is three years, and the agreement with Messrs. Johnson and Phillips, we understand, provides for a start to be made with the work within a month from the signing of the contract. It is also stated that it is the intention of the company, as soon as the Guildford to Stoughton line is completed, to apply for powers to construct tramways from the town to Merrow, and to Shalford, in accordance with the proposals originally made. Each of these lines will be independent of the other, and, as at present proposed, neither will cross High-street, although they will be brought as close together at the Guildford termini as possible.

West Bromwich.—The Highway Committee of the Corporation report that for some time past they have, together with the Electric Lighting and Power Committee, been in connection with the South Staffordshire Tramways (Lessee) Co. with reference to matters in dispute between the Corporation and the company. A settlement of these matters has now been arrived at. The company has paid certain arrears due for electrical energy supplied, and is to be allowed to run smaller cars, which must be of a type approved by the committee. A time-table giving the tram service in the borough has been submitted and agreed upon, and is to be in force for a year. This provides a less frequent service than five minutes between Handsworth and Carter's Green, and 10 minutes between Carter's Green and Great Bridge and Wednesbury respectively—namely, 7½ minutes and 15 minutes. In consideration of the above alterations, the company agrees to take a minimum supply of electrical energy of 900,000 units per annum, instead of the minimum of 300,000 per annum provided in the lease, but at the prices fixed by the lease, this minimum price to be continued during the term of the lease.

Liverpool.—An inquest was held last Friday on Catherine McNair, who was killed by an electric train on the Lancashire and Yorkshire Railway at Formby, near Liverpool. The evidence showed that the deceased waited for a steam train to pass, and was going over a level crossing when an electric train knocked her down. The horn of the electric train was not sounded when approaching, but it was promised that a recommendation of the jury that the horns should be sounded when approaching all level crossings should be placed before the proper authorities. The coroner said that, although he had no power to compel the railway to do it, the public ought to have better protection on certain portions of this line. At the last meeting of the Council it was moved that the Tramways Committee be instructed to institute a service of motor omnibuses on the Edge-lane route to meet the convenience of the inhabitants of this residential district, and that they be instructed to issue, before 7 a.m. (as an experiment for six months) return tickets on payment of a single fare, such tickets being available for the return journey at any time on the day of issue. These matters were referred to the committee for consideration.

Tramway Accident.—Lord Salvesen closed the record and ordered issues for the trial of an action at the instance of Hector Mackenzie Lamont, stationer and newsagent, Main-street, Wishaw, against the Lanarkshire Tramways Co., Edinburgh-road, Motherwell, for £760 for personal injuries. On Wednesday, June 7, 1905, the pursuer was a passenger by one of the defenders' electric cars from Wishaw to Motherwell. At a bridge near to the boundary line of the burgh of Wishaw, and to the east of the Lanarkshire Steel Co.'s works, the trolley pole, which under the bridges is almost level with the heads of the passengers, left the wires. When the car came from under the bridge the trolley pole swung round and struck the pursuer violently on the head, throwing him to the other side of the car. The pursuer says his injuries confined him to the house for eight weeks and to bed for five, while he still suffers from the effects. He avers that the car was being driven recklessly and at an excessive rate of speed, and says that for the safety of the outside passengers the conductor should have guided the trolley pole when passing under the bridge. The defenders admit that the pursuer was struck by the trolley, and that the pursuer was bruised, but they aver that the pursuer's injuries are greatly exaggerated. The accident, they say, was the result of a pure misadventure which no care on their part could have averted.

London County Council.—On the recommendation of the Finance Committee to invest £66,787 of the tramways renewals reserve fund, Sir M. Beachcroft at the usual weekly meeting on Tuesday said it was stated that the reserve fund now stood at £83,000, but he would like to know what 1d. per car mile placed to the renewals fund would represent. It was a big question whether 1½d. per car mile was not the right sum to put away, and they were told that 1d. ought to be the minimum. The Chairman of the Finance Committee promised to give information on the point. The Highways Committee recommend that the estimate of expenditure on capital account of £32,000, submitted by the Finance Committee, be approved in respect of the road work and platelaying (including rails) for the reconstruction of the existing tramways in Vauxhall Bridge-road, and the construction of tramways over the new Vauxhall Bridge, for the underground conduit system of electrical traction; that expenditure on capital account not exceeding £5 300 be sanctioned for the provision of track and slot rails, etc., for the reconstruction of the tramways in Vauxhall Bridge-road, and the construction of tramways over the new Vauxhall Bridge, for the underground conduit system of electrical traction; and that the offer of Messrs. J. Mowlem and Co. to execute for the sum of £4,995 the road work and platelaying in connection with the construction of tramways over the new Vauxhall Bridge for the underground conduit system of electrical traction be accepted.

Lancaster.—In future, all children under the age of 12 years are to be allowed to travel on the tramcars at half fare, the minimum fare to be ½d., and workmen will be allowed to use the return half of their tickets at any time during the day on which such tickets are issued. At the last meeting of the Council it was reported that Messrs. Kershaw and Co. had submitted a summary of their proposals with reference to the Lancaster and District Tramways for discussion, as follows: (1) The Corporation to agree to defer its power to purchase the company's undertaking for a period of 42 years from August, 1910, the date at which such powers may be exercised. (2) In the event of the Corporation purchasing the reconstructed undertaking, Section 43 of the Tramways Act not to apply, the price to be paid by the Corporation to be at fair market value as a going concern, but without allowance for compulsory purchase. (3) The Corporation to consent to the doubling and use as a double line of the present lines of the company within the borough, except in North-street, Cable-street, and the portion of Stonewell between those streets. (4) The Corporation to consent to the company employing the overhead system of electric traction; the designs and positions of the posts and the description of cars to be to the reasonable approval of the Corporation. (5) The company to apply for the necessary powers to construct a tramway to Skerton—this line would form a junction with the company's lines at the intersection of Owen-road and Heysham-road, and to be of single line with passing places. (5) The company to take a supply of electrical energy to operate the tramways within the borough from the Corporation at a price to be agreed upon. After full discussion it was arranged that Mr. Kershaw should reconsider the whole matter, and then submit other alternative proposals for consideration by the committee.

Dundee.—The Dundee-Broughty Ferry tramway is approaching completion, and our announcement made two weeks ago that traffic would be running over the line by the New Year seems likely to be fulfilled. The tramway is five miles long, representing about nine miles of single track. From end to end the rails are laid, the poles and brackets for carrying the conductors are erected, and the permanent way is all but completed. Operations are being pushed forward with dispatch, particularly at that part where the line departs from the highway and enters upon the lands of Craigie. Here the curve has been opened out, and stretching ahead is a straight of some 500 yards, upon which a high rate of speed can and will be attained. Over this portion of the line there is a noteworthy change in the construction of the permanent way. The rails are laid between whinstone setts, but the intervening space is filled in with tar macadam superimposed on a bottoming of rubble and concrete. The overhead equipment, as stated, is well forward, and underground cables are laid as far east as Craigie-terrace. At Dundee boundary, where the company's lines merge into those of the Corporation, the necessary junction and electrical bonding have been made. A good deal of work remains to be done at the power station and administration departments at Milton of Monifieth. A large staff of men are engaged. About one-third of the extensive car-sheds has been roofed, and this work has been completed so far as the engine-house and power-house are concerned. The engines and boilers have been placed on their seats. Inside the flooring is being laid down, and the completion of the stalk will be hastened so as to admit of steam being got up on as early a date as possible. A sub-committee of the Tramway Committee recently made a visitation with a view of determining a site for the proposed shelter at the junction of Constitution-street and Hilltown. The committee, in view of the alteration of service which will follow the opening of the Broughty line, deferred making a recommendation, the understanding being that the whole question of shelters would be discussed at an early date.

Wandsworth.—With reference to the resolutions passed at the last meeting of the Council relative to the suggested widening of York-road, Wandsworth, in connection with the proposal to reconstruct for an underground conduit system of electrical traction the northern

Digitized by Google

route of the tramways acquired from the South London Tramways Co., and the proposed construction of a tramway from Clapham, *via* north side Clapham Common and Cedars-road, to Lavender-hill, the Highways Committee have forwarded the following estimates to the Finance Committee for submission to the Council—viz.: (*a*) For acquisition of property required to widen York-road, Wandsworth, to 54ft., where such width can be obtained without interfering with buildings, £12,000 (total estimated cost £12,000, Borough Council to carry out widening. London County Council to contribute two-thirds of cost). (*b*) For one-third of cost of (1) wood paving, etc., carriageway of Long-road and north side Clapham Common from south side to Cedars-road (total estimated cost of work, £4,600); (2) constructing surface-water sewer along Long-road (total estimated cost of work, £561), £1,720. Regarding the plan received from the London United Tramways Co. showing the proposed positions of manholes on the line of the company's electrical cables from Lots-road, Chelsea, through Wandsworth to Wimbledon, as follows—viz.: (1) in Merton-road, near Lavenham-road; (2) in Buckho'd-road, underneath sewer aqueduct; (3) in North-street, near South-Western Railway bridge—the Highways Committee recommend the Council not to object thereto, subject to the exact positions of the manholes being approved by the Council's surveyor, to the whole of the works being carried out to his satisfaction, and to the Council's usual charges for reinstating the surface of the public way being paid by the company. The town clerk reports that the following parliamentary plans have been deposited: (1) London County Council (tramways and improvements)—(*a*) tramway from Queen's-road, crossing Wandsworth-road and passing along Cedars-road, Clapham Common north side, and the roadway crossing Clapham Common, to join the existing tramway at Clapham Common south side; (*b*) tramway from the existing tramway at the Broadway, Tooting, along Mitcham-road to the county boundary; (*c*) tramway from the existing tramway terminus opposite the Tate Public Library, passing along Streatham High-road to the county boundary, providing for a single up line in the part of Streatham High-road between Stanhope-road and Gleneldon-road, and a single down line leaving Streatham High-road opposite St. Leonard's Church and passing along Gleneldon-road, Bournevale-road, and Stanthorpe-road to rejoin the line in Streatham High-road.

Hastings.—The Town Council had under consideration at their last meeting a report presented by the borough engineer with reference to the Old Town tramways. The engineer thought that, instead of forming an additional roadway, it would be desirable to widen one or other of the existing ones. He submitted an estimate of the cost of carrying out the High-street widening scheme which was as follows: purchase of properties, including compensation to tenants, etc., £61,038; laying-out the new road, £4,900—total, £65,938. Amount to be realised for sale of the land, £11,482; contribution from tramways company, £5,000; portion of roadway to be paved at the expense of the Corporation, £340—total, £16,822, making a net cost of £49,116. With regard to the laying of a tramway down through the widened road, the engineer proposed that a single line only should be laid, with a passing place between Swan-lane and Courthouse-street, another between Salter's-lane and the south corner of the garden of Old Hastings House, and a double line from the bottom of Harold-road brought down as far as the north end of Torfield House. With regard to the All Saints scheme, the widening would be entirely on the west side of the road, which comprised 105 separate properties. In this scheme it was proposed to entirely sweep away the buildings at Mercer's Bank. The street would be of a uniform width of 40ft., and it was proposed to pave it with wood blocks. The estimated cost of scheme would be as follows: purchase of properties, £39,381; laying-out and paving new road, £8,248—total, £47,629; estimated amount for resales, £6,970; contribution from tramways company, £5,000; portion of roadway to be paved by the company, £1,786—total, £13,756—leaving a net cost of £33,873. The tramway would be laid as a single line from the commencement of the "Wilderness" property, with two passing places in the street, and then widening out to a double line at the south end. The company would prefer the High-street scheme, but he could not see that it would make the slightest difference to them as regards either passenger traffic or the construction of the tramway. It was doubtful whether the Board of Trade would sanction a single line of tramways up High-street without widening the roadway so that there would be sufficient room for a vehicle to pass the car on the east side, although powers have been obtained to lay tramways in streets equally as narrow as High-street, and the cars could be controlled by electric signalling in an exactly similar manner to the method adopted at Dover. He thought, however, that to lay down a tramway through High-street without it being widened would be found a great hindrance to business. It was agreed that the report be printed and circulated among the members of the Council.

LIGHTING AND GENERAL.

Monmouth.—The Town Council have decided to lay a new electric cable at a cost of £107.

Long-Distance Telephone.—The new telephone between Rome and Paris will be opened early next year.

Birmingham.—A reduced scale of charges for electric current will come into effect in the quarter commencing Jan. 1, 1906.

Hastings.—In future the electricity accounts will be made up to March 31 in each year, instead of up to Dec. 31, as hitherto.

Clacton.—The agenda for Wednesday's meeting contained a motion referring to an important modification of the electric lighting scheme.

Dublin.—An inquiry has been held into the Corporation's application for sanction to borrow £100,000 for electric lighting works extensions.

Maidenhead.—Extensions are to be made to Taplow at a cost of £430 and £25.

Chelmsford.—The Town Council have asked the Chelmsford Electric Lighting Co. to instal flame arc lamps and incandescent lamps with clear glass globes.

Eastbourne.—During the half-year ending Sept. 30, 1905, 1,036 consumers with 76,204 lamps were connected, as against 937 and 67,946 respectively in 1904.

Sunderland.—An extension to the Hylton-road power station and the installation of four new boilers and certain other plant at an estimated cost of £16,000 is being recommended.

Stock Exchange.—The Stock Exchange Committee have ordered the Oriental Telephone and Electric Co.'s £100,000 4 per cent. redeemable debenture stock to be quoted in the official list.

Western Telegraph Co.—The directors of this company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, for the quarter ended Sept. 30, 1905.

Islington.—It has been decided to heat the Council's strong rooms by means of four electric radiators at a cost not exceeding £42. Mains are to be laid in the City-road at a cost of £575.

Poplar.—A resolution approving of the steps taken by the London County Council with respect to the question of cheap bulk electricity for the Metropolis has been passed by the Borough Council.

Stafford.—A report submitted at the last Town Council meeting showed that during the quarter ended September the output of gas had increased by 12·94 per cent., and that of electricity by 25 per cent.

Barsi Light Railway Co.—The directors of the Barsi Light Railway Co. recommend a final dividend at the rate of 3½ per cent., making 6 per cent. for the year to June 30, carrying forward £3,213.

Pentypridd.—The National Telephone Co. and the Post Office have completed the additional wiring and connections preparatory to intercommunication between the subscribers of both systems within the local area.

Brighton.—A committee of the Council have refused to recommend the application of the National Telephone Company for permission to place their lines underground. The total expenditure was estimated at between £40 000 and £50,000.

Falmouth.—The Chamber of Commerce has been considering the telephone service of the railway company, and consider it objectionable to have the call office at an hotel. It is suggested that another office be established near the post office.

New Address.—Mr. George A. Goodwin, M.I.C.E., Whit.Sch., and past-president of the Society of Engineers, has removed his offices from 28, Victoria-street to 25 Victoria-street, Westminster, where he practices as a consulting engineer and mechanical expert.

Rand Central Electric Co.—The following figures are given for November: kilowatt-hours generated, 866,000, yielding a gross revenue of £8,100. For the corresponding period of last year the result was: kilowatt-hours generated 795,000, yielding a gross revenue of £7,450.

Oerlikon Steam-Turbines.—The Maschinenfabrik Oerlikon has appointed Mr. G. Wüthrich, 19, Barclay-road, Fulham, S.W., manager of their British, Irish, and Colonial department and London resident engineer, with offices at Oswaldestre House, Norfolk-street, Strand, W.C.

Dover.—It has been decided to purchase a 50-kw. transformer at a cost of £65 to replace two smaller ones to be used in outlying districts. Some old plant was recently sold for £52. 10s. The Electricity Committee is considering the proposed increase of the power plant.

London County Council.—On Tuesday it was agreed to lend the Woolwich Borough Council £820 for electric lighting purposes and £7,500 for electric light installation. Improvements are to be effected to the electric lighting at the Fulham Palace-road school at an expenditure of £55.

Warrington.—The following scale of charges for electric energy supplied for power purposes has been adopted: load factor, 40 per cent., 1·0d. per unit; 50 per cent., ·94d.; 60 per cent., ·88d.; 70 per cent., ·82d.; 80 per cent., ·76d.; 90 per cent., ·70d. Intermediate values of load factor will be worked out proportionately.

Colchester.—The borough electrical engineer's last report contains the following figures: Output of electricity (lighting) in units during October, 1905, 75,248, (1904, 56,018); ditto (traction) ditto, 32,759 (35,540); ditto (used in generating station), 4,314 (—); number of consumers at end of October, 803 (576); total number of 8 c.p. lamps connected, 34,950 (27,381).

Change of Address.—We are informed that, owing to greatly increased business, Messrs. Bruce Peebles and Co. have transferred their London office from Westminster to 1, London-wall-buildings, E.C., which will be the headquarters of Mr. Roland S. Portheim, managing director, with Mr. Morton Beales as manager and Mr. W. J. W. Bullock as chief engineer of the contract department.

Bedford.—The last report of the Electricity and Street-Lighting Committee recommends that the electrical engineer be empowered to purchase the following materials—viz.: four-light radiator, £2. 4s. 6d.; frequency indicator, £5. 10s.; 220 yards $^{7}/_{16}$ twin service cable, £26; drawing-paper cupboard, 10s.—total, £34. 4s. 6d.—and that extensions of private mains be carried out at a cost of £73.

Stepney.—Applications by the Postmaster-General for the Council's permission to the placing of an overground telegraph pole at the south-west corner of the north side of Trafalgar-square, and to the placing of an underground telegraphic pipe along north side of Cable-street and east side of Christian-street, from 85, Cable-street to 10, Christian-street, also to building boxes, have been granted.

New Firm.—Messrs. L. E. Wilson and Co. have commenced business as telephone experts and engineers at 20, Cross-street, Man-

Digitized by Google

chester. Mr. L. E. Wilson was formerly chief electrician of the National Telephone Co. in the Manchester district, and with the aid of his wide and varied experience this firm should meet a decided want, in view of the rapid strides in telephone work now being made in this country.

Wednesbury.—The auditor (Mr. T. H. Gorle) in his report on the accounts of the electricity department for the year ended March 31 last points out that, taking into consideration the fact that two-thirds of the loss on the first year's working arose from capital charges (paying off a portion of the principal and interest on loans), it did not show up so badly, being about equal to 1d. in the £ on the rates for the actual trading.

Edinburgh.—The lighting of side streets was further discussed on Wednesday. It will be remembered that the Electric Lighting Committee have been experimenting in certain streets with the Nernst lamp, supplying to the Cleansing and Lighting Committee current at the ordinary gas rates. A proposal by the electrical engineer to provide Nernst lamps at 47s. each was referred to the Cleansing and Lighting Committee.

Middlesbrough.—An application from the Cleveland and South Durham Electric Power Co. asking for the necessary consent of the Corporation to supply power to Messrs. Sir Raylton Dixon and Co., the Grand Opera House, and Messrs. Richardsons, Westgarth, and Co., the probable total demand being a million units per annum, has been declined, on the ground that the Corporation was already supplying on reasonable terms.

Wisbech.—The Town Council have confirmed their previous resolution to apply to the Board of Trade for a further provisional order under the Electric Lighting Acts, 1882 9, amending the provisional order of 1901 and enabling the Council to transfer their order, with its powers, duties, and liabilities, to a company, and to pass such further resolution as may be necessary in accordance with Sub-Section 6 of Section 3 of the Electric Lighting Act, 1882.

London Gazette.—The partnership between L. L. Hermes and W. A. Wallis, electrical engineers and contractors, 29, Uxbridge-road, Ealing, Middlesex, has been dissolved by mutual consent. A receiving order has been made out on debtor's petition in the estate of J. W. Smith, electrical engineer and contractor, 55, Bolton-road, Darwen. The first meeting in the estate of W. G Leather, electrical engineer, 25 Howard-street, Sheffield, will be held at the official receiver's offices, Figtree-lane, Sheffield, at 1.30 p.m. on Dec. 13.

Westminster.—Applications have been received from the General Post Office for consent to the placing of underground telegraphic lines in Hazlewell-road and in Gwendolen-avenue, Putney; from the County of London Electric Supply Co. to lay conduits in Hotham-road, Putney; and from the General Post Office to fix a stay to the existing telegraphic post on the eastern side of The Platt, Putney, near North-place, and to erect an overground telegraphic line from existing overground line in Priory-lane to Templeton House, Roehampton.

Hackney.—The Borough Council have confirmed the application for a Bill in the next session of Parliament conferring further powers on the borough, including provisions to enter into agreements with other local authorities for giving or taking a supply of electrical energy in bulk or otherwise. It was explained that the Bill would not in any way be antagonistic to that of the London County Council, and its object was to protect the rights of the Borough Council. This year the undertaking had yielded £1 400 towards the relief of the rates.

South Shields.—The quarterly statement of the electricity undertaking shows that the number of units consumed during the last three months was 138 086, as compared with 137,250 in the corresponding period of last year. The value of the current sold was £2,431, which, with meter rents and the proceeds of public lighting, brought the total amount from sales to £3,428, as against £3 664 in the corresponding three months of 1904. The reduced revenue is accounted for by the fact that the average price per unit last quarter was 4·23d., as compared with 4·71d. in the same period of last year.

Underground Telegraphic Cables.—At the meeting of the council of the Newcastle and Gateshead Chamber of Commerce on Wednesday, the Secretary said that the underground cable was being pressed forward as much as possible. The Postmaster-General had written stating that he hoped that the cable would be complete from London to Glasgow by the end of the current financial year. A spur line from Warrington, on the main underground line to the North, had been constructed through Manchester and Bradford to Leeds, with the intention of bringing it forward to Newcastle.

West Cumberland.—The West Cumberland Power and Tramway Co. will shortly erect a large central generating station from which iron mines, collieries, and works will be supplied with cheap electrical energy. The same generating station will supply current to tramways which the company will construct between Maryport and Whitehaven, and also for lighting purposes in certain districts. Sir Douglas Fox and Partners and Messrs. Harper Bros. estimate that the demand for industrial power alone will be equal to 15,000,000 units per annum, and that the total annual net return will be £27,150.

Wrexham.—The borough electrical engineer's last report shows that there have been used for tramways in October, 1905, 11,852 units and for lighting, etc., 36,317 units: the total consumption was 48,169 units as against 39,440 units in October, 1904. Six new consumers were connected, the total number of consumers now being 197. The Mayor and Councillor Hughes have been appointed a committee to consider the question of fixing a scale or basis of charges for materials supplied to and work done for consumers, and matters relating to the users of the department and to advise and report thereon.

Liverpool.—It is proposed that the resolution of the Electric Power and Lighting Committee of Dec. 1, 1905, as to the supply of motors on hire—"That the consulting and resident electrical engineers be instructed to prepare a detailed report showing the proposed working, and how the proposal will be carried out, also a statement of the financial result, increased cost, etc., and that the consideration of the report be deferred until the detailed report is received"—be not approved, and that in lieu thereof the report of the consulting and resident electrical engineers upon the subject be approved.

St. Annes.—In his last report Mr. J. H. Clothier, the electrical engineer, gives the following particulars: units sold during October, 47,966; units sold to Oct. 31, 356,095; equivalent to 8-c.p. lamps connected, 20,099; units sold per 8-c.p. lamp connected, 5 78; maximum load, lighting 199 kw., traction 105 kw.; total number of consumers, 383. Applications received, 11 for 353 8-c.p. lamps. The arrangements for connecting the feeder and balancer at the tramway sub-station are complete. The offer of Messrs. Pearson and Son to affix their smoke-preventing apparatus to one of the boilers at the electricity works has been accepted. The question of the revision of the prices charged for electrical current has been referred to the Electric Lighting Sub-Committee for report.

Crewe.—New offices have been completed in Gresty-road, on the southerly side of the station, for the accommodation of the electrical and telegraphing engineering staff of the London and North-Western Railway Co. Mr. A. M. Thompson, chief of the signalling department, has charge now of the telegraph department, and the members of the staff are being moved from the locomotive offices to the new buildings, and about 100 men, comprising the electrical and telegraph staff at Stockport, are being drafted to Crewe so as to concentrate there the chief officers under Mr. Thompson. Important developments in connection with the electrification of further large signal boxes are contemplated at the north end of Crewe Station, and when these are completed they will contain, it is said, the largest electric signalling apparatus of any railway station in the country.

Coventry.—The City Council had before them on Tuesday a report from a special committee recommending that no alteration be made in the present scale of charges either for gas or electricity. Regret was expressed by the chairman of the Electricity Committee at the result of the investigations, and he mentioned that in consequence of this the electricity department had lost one valuable customer and the gas department another. It was mentioned that in the neighbouring town of Birmingham it was decided to alter the prices of both gas and electricity, but Alderman Andrews, for 15 years chairman of the Coventry Gas Committee, cast doubts on the wisdom of such a course, and urged that it was unwise to expend about £24,000 simply to accommodate one firm. Councillor Gardner advocated the appointment of a board of reference for such matters as affected both departments, and Councillor Errington favoured the two departments being managed by a joint committee. The report was adopted.

African Rubber.—The report for 1904 on the Gold Coast by the Acting Colonial Secretary (Mr. C. H. Hunter) states that attempts have been made to encourage native planters to form plantations of the indigenous rubber trees, but, owing to the apathy of the chiefs, these have not hitherto meet with much success. Samples of Para rubber grown in the gardens at Aburi have been very favourably reported on, and the prices quoted for samples shown in the English market compare well with the Ceylon and South American product. Sir W. T. Thistleton-Dyer, writing on the subject, has expressed the opinion that "the production of Para rubber on our West African Colonies is an enterprise which has now emerged from the experimental stage, and may be safely encouraged by the Colonial Governments." The Para rubber tree, says Mr. Hunter, appears to be the most satisfactory rubber-producing plant to cultivate in the Gold Coast, and steps are being taken to procure further supplies of seeds from Ceylon and the Straits Settlements for intending planters, with a view to foster the interest aroused in the cultivation of this very valuable product.

Cardiff.—At the last meeting of the Asylums Committee Mr. Arthur Ellis, electrical engineer, submitted a report in connection with the electric lighting of the Whitchurch Asylum, the contract for which was placed in the hands of Messrs. D. Furth and Son, of Manchester. Mr. Ellis said there were altogether 3,604 lights to be wired, and the contractors had asked him for a certificate for £1,012, and his refusal had led to the present trouble. The next lowest two tenders were those of Messrs. Lee and Warren, Kettering (£6,491), and Messrs. Clay Bros. and Co., Cardiff (£6,964). The committee resolved that notice be given to the contractors that the work be proceeded with in a reasonable manner and with reasonable dispatch, and, failing this, that further notice to determine the contract be given; further, that notice be given to the sureties of the steps taken and contemplated by the Corporation, and that, in the event of the contract being determined, the same be relet to Messrs. Lee and Warren, or, failing them, to Messrs. Clay Bros. and Co., upon the terms of their tenders respectively, subject to their sureties being deemed satisfactory. An application of the National Telephone Co. for permission to place their wires underground has been referred to the Public Works Committee.

Gloucester.—At the last Council meeting the Electricity Supply Committee submitted Mr. White's further figures and information with reference to the charges for the supply of current for power purposes, and it was resolved that it be recommended that the following reduced scale of charges for the supply of electrical energy for power purposes only be adopted as from the end of the current quarter: for the first 200 units per quarter, 2d. per unit; for the next 1,000, 1½d.; for the next 10,000, 1¼d.; and for all beyond 11,200, 1¼d. It was reported that the representatives appointed by the Electricity Supply Committee and the Light Railways Committee to confer as to the price to be charged for current required for the light railways undertaking had conferred as to the question, and ultimately left it to the then mayor to suggest what would be a fair charge as between the two committees, and that the mayor had come to the conclusion that a charge of 1d. per unit was a reasonable and proper rate to be

Digitized by Google

charged for the supply of electrical energy for the light railways, and that such charge should commence as from the end of the last municipal financial year—namely, March 31 last. The committee's recommendation that such charge be adopted for the current municipal financial year was agreed to.

St Pancras.—A special meeting of the Council is to be held at the Town Hall, Pancras-road, N.W., to-day, to consider as to passing resolutions in regard to the Council's application to Parliament in the ensuing session for an Act for all or any of the following purposes—that is to say: (1) to empower the Council to continue, maintain, and extend their stations for generating, transforming, converting, and otherwise dealing with electricity upon lands in their possession; (2) to empower the Council to continue, maintain, and from time to time extend, enlarge, improve, rebuild, and use their dust and refuse destructor upon lands in their possession; (3) to exempt the Council in respect of all lands used in connection with their electricity and dust destructor works from all indictments, actions, and other proceedings for nuisances; (4) to provide for the payment of the expenses of carrying the intended Act into execution, and for the borrowing of money; (5) to alter or repeal all or some of the provisions of the St. Pancras (Middlesex) Electric Lighting Order, 1883, and any Acts or orders relating to the Council; 6) to vary and extinguish all existing rights and privileges which would or might interfere with or delay the accomplishment of any of the objects of the intended Act, and to confer other rights and privileges; (7) to provide for meeting the expenses in connection with the promotion of the said Act.

Fulham.—In their last report the Finance Committee made the following recommendations: "That the Council concur in the suggestions of the auditor that the electricity revenue shall be charged with an appropriate share of the central establishment expenditure, and that such amount be fixed at £200 instead of £100 per annum; that the electricity revenue shall also be charged with the actual cost incurred by its overdraft on cash account; and that the borough treasurer be instructed in future when the electricity account or the general account is overdrawn, and the money is not provided by the bank, but transferred from one account to another, to credit the interest of such overdraft to the general rate, or *vice versa*, at the same rate as would have been paid to the bank had the money been drawn from them. That no alteration be made in the present system of the collection of the electric lighting accounts, and that the period of 14 days from the date of demand for the allowance of discount be adhered to; also that the demands be delivered in batches as at present. That in view of the auditor's stand in cutting out from the accounts the loans of £3,600 from the electricity reserve, and £5,000 from the cemetery reserve to the works department for wood paving, the borough treasurer be instructed, in order to comply with the requirements of the auditor, to adopt a different method in transactions of this nature in future, and that he keep an internal account of these loans with a view to paying same back by way of contributions from the rates.

Lewisham.—Applications from the South Metropolitan Electric Light and Power Co. giving notice of their intention to (1) lay two $^{19}/_{16}$ high-tension concentric lead-covered cables from the existing mains on the west side of High-street, Lewisham, across that thoroughfare to the south-west corner of Court Hill-road, along the south side of the latter thoroughfare in an easterly direction for a distance of about 410 yards, and crossing to the London County Council sewer works, also two similar cables from Court Hill-road, along the north side of Hither Green-lane in a westerly direction for a distance of 66 yards, and crossing to the north-east corner of Ladywell Park-terrace and thence along the east side of that thoroughfare in a southerly direction for a distance of about 87 yards to the London County Council sewer works; (2) the laying of $^{19}/_{09}$ low-tension concentric lead-covered cables from a proposed junction box on the east side of Clarendon-road, at the south-west corner of St. Mark's-road, along the south side of the latter thoroughfare in an easterly direction for a distance of about 76 yards; (3) the laying of a similar cable from the north-east corner of Wisteria-road, on the west side of Gilmore-road, along the west side of the latter thoroughfare in a northerly direction for a distance of 107 yards, the cable to be placed in earthenware troughs filled with bitumen and laid under the footway where possible; and (4) from the General Post Office for permission to place an underground telegraphic line along the north side of West-hill, east side of Taylor's lane, south and west sides of Coombe-road, Sydenham, from the existing line on the north side of West-hill, at the west corner of Ormanton-road, to the north-west corner of Coombe-road, and to erect a fire alarm post at the latter point, have been agreed to.

St. Marylebone.—The Electric Supply Committee have reported as follows on the question of additional plant which will shortly be required in connection with the undertaking: "Under the Council's Act of 1904 the sanction of the London County Council is required before money can be borrowed for expenditure in this connection. The approximate amounts which will be required are as follows: a ninth turbine (to be supplied by Messrs. Parsons and Co., the contractors for the electrical plant) at the generating station, £10,000; a storage battery at North-street sub-station, £10,000; a storage battery at Rathbone-place sub-station, £5,000; two boilers at the generating station, £9,000. With regard to the turbine, it probably will not be actually required for a year, but we consider it would be a wise precaution to put the order in hand at once in order to ensure a sufficient reserve plant being in hand in the event of the failure of one of the present large turbines. The expenditure in respect of the storage batteries at North-street and Rathbone-place has always been contemplated, but the cost of these will be covered by the £15,000 which (under the provisions of the order of the Court of Aug. 7, 1903) the Metropolitan Electric Supply Co. have to repay to the Council in respect of the nine motor-generators at North-street, which they (the company) are now arranging to take back. The additional battery power at North-street is necessary to ensure a continuity of service to Hertford House, and in the recent negotiations with the Office of Works we undertook to instal this additional power by March next. In order to ensure the Council being in a position to take over the supply of the whole of the consumers in the borough by the end of March next, it is, in the opinion of the consulting engineer, necessary to immediately order the storage battery at Rathbone-place. We are inviting tenders for the batteries required, and will submit recommendations to the Council in due course. The two new boilers will be required for the ninth turbine above mentioned, and the contract for the same should be put in hand during the forthcoming year. We have referred the matter to the Finance Committee to consider as to the application to be made to the London County Council for sanction to the borrowing of money necessary for the foregoing additional plant." It has been decided to lay a second set of service lines to Hertford House, and to instal a change-over switch so that a supply may be given either from the special feeder or from the street distributing main. Messrs. Wheatley Kirk and Price have been instructed to sell old meters and other apparatus.

Bermondsey.—The Electricity, etc., Committee on Tuesday reported the receipt of the following letter from the London Electric Supply Corporation to the town clerk: "Dear Sir,—I have submitted your letter of 15th inst. to our managing director. He is sorry to be at issue with you, but he is quite confident that his recollection of what passed between you and him on the occasion referred to is correct, and he is entirely at a loss to understand how it is that your recollection of what actually transpired on that occasion is diametrically at variance with his. He quite recognises that an opinion expressed by you in the ordinary course of conversation cannot, in any sense, be interpreted as that of your committee or be regarded as committing them, however remotely, to the adoption of that or a similar opinion. If you or your committee have been under the impression that our managing director entertained any such idea, I trust that what I have stated will suffice to dispel it. In regard to your committee's repudiation of the suggestion that the Council's electric lighting undertaking is a burden upon the rates I would refer you to a circular letter issued in December, 1904, by the Municipal Association for Bermondsey and the neighbouring district, wherein it is stated that the constant recourse to loans inflicts serious burden upon the ratepayers, and that the ratepayers are year by year experiencing a large loss by the electrical lighting undertaking. That letter bears printed upon it the names of gentlemen who, it is presumed, are of sufficient intelligence to gauge the effect upon ordinary minds of statements purporting to emanate from them. It is fitting, perhaps, that I should state that the corporation is not a member of the association in question. In regard to your remark that your committee is not prepared to accept the statement in my letter that this corporation could supply your Council with electrical energy in bulk at a price below that at which they themselves can generate it, it is to be observed that your committee's opinion upon this point has been arrived at in the absence of any quotation from this corporation, and cannot, therefore, be regarded as well founded. I would remark that this corporation, in endeavouring to enter into business arrangements with your Council, had not the remotest intention of seeking to induce the Council to abandon their electric lighting undertaking; the object, as has been previously stated, was to reduce the Council's generating expenses. Referring to the last paragraph of your letter, it only remains for me to add that any such arrangement as that proposed, if entered into, would certainly not have the effect of compelling the users of electricity to pay a higher charge for lighting and power; on the contrary, its tendency would inevitably result in a lowering of prices to the consumer, and would undoubtedly reduce the cost of the supply to the public lamps.—Yours faithfully (signed) H. C. CARTER, secretary." To this letter the town clerk had replied as follows: "Nov. 27, 1905. Dear Sir,—I have submitted your letter of the 14th inst. to my Electric Lighting Committee. I regret you should still insist upon your entirely erroneous version of what passed between your managing director and myself, and am compelled again to repudiate the statement that I expressed any approval of your managing director's proposals. With regard to your suggestion that the Council's electric lighting undertaking is a burden upon the rates, my committee is of opinion that you should have taken some means to make yourself acquainted with the facts of the case rather than rely upon a statement circulated by the irresponsible body described by you as the 'Municipal Association for Bermondsey and the neighbouring district.' The accounts of the electricity department of the borough of Bermondsey (examined and passed by the district auditor appointed by the Local Government Board) are published, so that any ratepayer may have access to them. It will be found they prove the reverse of the view you express and which you say is based upon the authority of the Municipal Association. As to the sufficiency of the intelligence of the gentlemen to whom you refer, my committee express no opinion, nor do they think it needful they should do so. May I point out that your suggestion that you could supply this Council with electricity in bulk at a price 'below that at which the Borough Council could generate it' was made without knowledge either of the present or anticipated future works cost of the Council's electricity department. My committee, moreover, is of opinion that there are more satisfactory means of reducing generating expenses than by falling in with your corporation's proposals. My committee remains of opinion that the reference in your letter of Oct. 26 to a suggestion to obviate any further capital outlay on the part of the Council in connection with its electric installation and thus 'put an end to the cutting rates' between this Council and your corporation, could only bear the interpretation that the business of supplying electricity would by becoming a monopoly do away with the wholesome competition which now ensures to the users of current fair and reasonable charges for power and light. My committee instruct me to say that it still thinks no good purpose would be served by the officials of this Council meeting your corporation, and is, further, of opinion that there can be no useful purpose served by a continuance of this correspondence.—Yours, etc. (signed) FREDK. RYALL, town clerk. The Secretary, London Electric Supply Corporation, 25A, Cockspur-street, S.W."

PROVISIONAL PATENTS, 1905.

Nov. 27.

24452. Improvements in incandescent electric lamps. Francis Harrison, 14, Ossian-road, Stroud Green, London.

24461. Improvements in or in connection with drain and sewer, water, and other pipes and electric conduits. Harold Easton Routledge, 3, Brown street, Market-street, Manchester.

24475. Improvements in appliances for carrying and suspending globes for inverted incandescent electric and other lamps. William Anderson and Henry Anderson, 41, Reform-street, Dundee. (Complete specification.)

24482. Improvement in electric incandescent lamp. Joseph Stwirsky, 36, Newman-street, London.

24494. Improvements in electrically-driven clockwork mechanism for registering and indicating purposes. William Robert Sykes, jun., Frederick Thomas Hollins, and Frederick William Leake, Walton House, Fillebrook-road, Leytonstone.

24502. Improvements in or relating to electric arc lamps. André Blondel, 111, Hatton-garden, London. (Complete specification.)

24507. Process for electrolytically producing peroxide of hydrogen. Gustav Teichner, 55, Chancery-lane, London. (Complete specification.)

24518. Self-generating steam or hot-air power electric machine. Carl Peter August Dahl, 77, Wells-street, Oxford-street, London.

24538. Improvements in electrodes for electrolytic apparatus. Franklin Wise Howorth, 46, Lincoln's-inn-fields, London. (Marie Kellner, Eglantine Kellner, Eleonore Kellner, Eduard Kellner, Marie Kellner, heirs of Carl Kellner, Germany.)

24539. Improvements in electric demand indicators. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Nov. 28.

24605. Improvements in printing telegraphs. Leo Kamm, 37, Powell-street, Goswell-road, London.

24621. Improvements in or connected with electromagnetic generators. Louis Alexandre Gianoli, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 2, 1904, being date of application in France.) (Complete specification.)

Nov. 29.

24718. Improvements in or relating to wireless telegraphy. Ferdinando Lori, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, Nov. 30, 1904, being date of application in Italy.) (Complete specification.)

24721. Improvements in insulators. Francis Heron Rogers, 16, Devonshire-square, London.

24724. Process for the electrolytic manufacture of metal tubes and other bodies. William Clark, 53, Chancery-lane, London. (Friedrich Darmstadter, Germany.)

24729. Improvements in and relating to electric controllers Claude William Atkinson, 1, Queen Victoria-street, London.

24747. Improvements in electric automobiles. Alfred Dinin and Maurice Espagnent, 40, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 9, 1904, being date of application in France.) (Complete specification.)

Nov. 30.

24761. Improvements in or relating to electric switches of the enclosed type. The Electric and Ordnance Accessories Company, Limited, Robert Frederick Hall, and Joseph Booker, 24, Temple-row, Birmingham.

24777. A mechanism for setting back the motion work and hands of electric clocks. Sharman Dermot Neill, 22 Donegall-place, Belfast.

24785. An improvement in the production of the electric arc for scientific and industrial purposes. Vladimir Mitkevitch, 10, St. George's crescent, Liverpool. (Complete specification.)

24794. Improvements in brush-holders for electrical machines. Herbert William Wilson, care of the East Anglian Engineering Company, Limited, Stowmarket, Suffolk.

24809. An improved system of syntonic radio-telegraphy Armande Parravano, 55, Chancery-lane, London. (Complete specification.)

24810. Improvements in the electrical control and propulsion of vehicles or trains of vehicles. John Smith Raworth and Arthur Basil Raworth, Queen Anne's-chambers, Westminster, London.

24811. Improved means of fixing an electric bell to an alarm clock and the like. Henry Richmond Rushton, 84, Ramsden-road, Balham, London.

24835. Improvements in or relating to electric bell pushes and in the manufacture of the same. George Thomas Piggott, 77, Colmore-row, Birmingham.

24850. Improvements in or relating to switches or controllers for electric motors for ships' steering gear, hoists, and the like. Joseph George Cockburn, 70, Chancery-lane, London.

24853. Improvements in and relating to electric switches. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24855. Improvements in and relating to electric resistances. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24856. Improvements in and relating to vapour electric apparatus. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

24858. Improvements in electric fire-alarm systems and apparatus. Harold Hawthorn, 40, Chancery-lane, London.

24877. Improvements in dynamo-electric machines. Arnold Frank Hills, David Urquhart, and Alfred Edward Honey, 4, South-street, Finsbury, London.

24882. Improvements in and relating to electric arc lamps burning mineralised carbons. Hippolyte Hegner, 65, Chancery-lane, London.

Dec. 1.

24902. Insulating supports for conductor rails of electric railways. Henry Lewis Doulton and Charles Edward Morris, Lambeth Pottery, London.

24931. Improvements in or relating to electrical time switches. Robert Francis Sidebottom Venner and Robert Constantine Griesbach, 37, Essex-street, Strand, London.

24943. Improvements in telephonic and other electrical apparatus. Maurice Ravel de Malval, 53, Chancery-lane, London.

24962. Improvements in or relating to electric traction systems. Edward Albert Mitchell and the Dolter Electric Traction, Limited, 46, Lincoln's-inn-fields, London.

Dec. 2.

24995. Method and means for the control of any bank of electric lamps displaying characters and the like. George Edward Carr, 46, Goldspink-lane, Jesmond, Newcastle-on-Tyne.

24996. Improvements in and relating to electric arc lamps. Llewellyn Burbank Codd, Standard Works, Dame Agnes-street, Nottingham.

24998. Improvements in trolley boom controlling apparatus for electric tramcar and the like vehicles. Samuel Hindley, 58, Bute-street, Sheffield.

25007. Improvements in trolley poles. Thomas Walls, 37, West Nile-street, Glasgow.

25023. Improvements in or applicable to electric lifts and equivalent apparatus. Henry Charles Edward Jacoby, 21, Finsbury-pavement, London.

25032. Improvements in electric stoves. Obed Charles Hawkes, 35, Temple-row, Birmingham.

25047. Improvements in and relating to vapour electric apparatus or devices. Sir Oliver Joseph Lodge, Knight, Alexander Muirhead, and Edward Ernest Robinson, 323, High Holborn, London. (Complete specification.)

25053. Improvements in and connected with the insulation of electric cables. The Land-und Seekabelwerke Akt.-Ges., 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, Dec. 2, 1904, being date of application in Germany.) (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 21.

1904.

25647. Space telegraphy. Stone. (Date applied for under International Convention, Nov. 25, 1903.)

26174 Electric transformers. British Thomson-Houston Company, Limited. (General Electric Company.)

27401. Electric motor control systems. British Thomson-Houston Company, Limited. (General Electric Company.)

28175. Electric tramways and railways. Baynes.

28827. Bolometers and space telegraphy. Stone. (Date applied for under International Convention, Feb. 15, 1904.)

1905.

617. Construction of splicing ear for electric trolley wires or the like. Phillips.

1391. Controllers for apparatus adapted to be operated by alternating currents. Jackson. (Date applied for under International Convention, June 6, 1904.)

2194. Inspection boxes for electric light leads and the like. Wenham.

2766. Locks and switches for gates of electrically-controlled lifts. Major, Stevens, and Stevens.

3009. Electrical tramway conduit systems. Fell and Rider.

3125. Electric motor starters. Jones.

3372. Casings for electric switches and fuses. Headley.

5197. Electric switches. Byng and Coates.

5295. Electromagnetic pump. Ibbetson.

Digitized by Google

6872. Ozonisers and like apparatus for treating gases electrically. Wood-Smith.

8267. Means for electrically recording weights lifted by a crane or the like Russo and Feinstein.

8739. Method for safeguarding electric unipolar cells. Grisson.

8921. Contact boxes for surface-contact electric railways. Campbell and Stephens.

10581. Devices for electrically operating the points on electric railways. Jokech, Petrik, and Butta.

11301. Couples for sulphide of copper thermo-electric generators. Cie. Thermo-Electrique (Systeme Hermite) Soc. Anon. (Date applied for under International Convention May 3, 1905.)

13662. Insulators of electric railways, tramways, and the like. Tweedy.

13707. Fluid-pressure brake systems for railway and tramway vehicles and the like. British Thomson-Houston Company, Limited. (General Electric Company.)

14465. Controlling and recording apparatus for use with electrical indicating instruments. Harrison. (Electric Railway Improvement Company.)

16518 Dynamo-electric machines. British Thomson-Houston Company, Limited. (General Electric Company.)

17079. Receivers for electric waves Schneider.

17823. Receiver system for wireless telegraphy. Harrison. (Date applied for under International Convention, Aug. 26, 1904.)

18214. Apparatus for broaching tanks or the like. Chloride Electrical Storage Company, Limited, and Benest.

18432. Electric lighting apparatus for use in connection with cycles and the like. Lewy.

22460. Electrodes. Yasuda. (Date applied for under International Convention, Jan. 21, 1905.)

NOTES.

Birmingham Electric Club.—At the annual meeting of the above on Saturday last, Mr. J. A. Jeckell, manager of the city of Coventry electric power station, was elected president for the ensuing year, and Mr. Riddle, of the firm of Inniss and Riddle, City-chambers, New-street, Birmingham, was elected secretary.

Change of Title.—Our Austrian contemporary, the *Zeitschrift für Elektrotechnik*, is extending its scope so as to include the construction of machinery. With the commencement of the year 1906 it will assume the title of *Elektrotechnik und Maschinenbau*, organ of the electrical industry in Vienna. We wish it success in its enlarged sphere.

Wireless Telegraphy.—The *Echo de Paris* states that the French Administration of Posts and Telegraphs have established three new wireless telegraph stations at Bizerta, Port Vendres, and Cherbourg. It is only intended to continue the experiments, which have hitherto not been sufficiently conclusive. The Administration hopes that the new experiments will give more decisive results than those made at Ile de Porquerolles and Ushant.

Books Received.—"La Théorie Moderne des Phénomènes Physiques," by Prof. Augusto Righi. Prof. Righi's work has been rendered into French by M. Eugène Néculcéa, and is issued from the office of *L'Eclairage Electrique*, Paris, with a preface by M. G. Lippman.—"The Practical Telephone Hand-Book," by Mr. Joseph Poole, A.I.E.E. (London: Whittaker and Co. 6s. net.) This is described as a guide to the telephonic exchange, and in it the author has succeeded in revealing its inner workings. It is intended to be of use to telephone employés and the general public.—"Practical Dynamo and Motor Construction," by Mr. Alfred W. Marshall (London: P. Marshall and Co. 1s. net), is a hand-book of constructive details and workshop methods used in building small machines.—"La Séparation Électromagnétique et Électrostatique des Minerals," by M. Désiré Korda (Paris: *L'Eclairage Electrique*).

Faraday Society.—Three papers were read before the Faraday Society at its meeting on Tuesday evening. The first, on the "Physics of Ore Flotation," was a joint contribution by Mr. James Swinburne and Mr. G. Rudorf, B.Sc., Ph.D., who argued that the theory that balls of sulphuretted hydrogen carry up particles of sulphide is invalid. The sulphides generally treated are not attacked by acid solution, so that there is no hydrogen evolved. The sulphides of zinc, iron, and manganese alone are attacked at all by dilute acids, therefore it cannot be the hydrogen sulphide that carries up the particles of sulphide. Prof. A. K. Huntington's paper dealt with the concentration of metalliferous sulphides by flotation, and had reference to the processes of Potter and Delprat. It was illustrated with a number of experiments. The last paper of the series was contributed by Prof. James Walker, F.R.S., and was upon the ions of pure water.

Tramways and Light Railways Association.—In the *Official Circular* for December is given a list of lectures and visits for which arrangements have been made. Last night (Thursday, Dec. 14), Mr. Elmer E. Cook (member) lectured "On Improvements in Trucks" (which we deal with separately), Mr. J. B. Hamilton (member of council) in the chair. On the afternoon of the same day the members visited the power station of the District Railway at Lots-road, Chelsea. A large attendance is expected in the theatre of the institution on Wednesday, Jan. 10, 1906, when Mr. A. L. C. Fell (member of council) will read his paper on "Brakes" before the association, and Mr C. R. Bellamy (vice-president) will take the chair. The *Circular* also contains a full report of Mr. Walter L. Green's practical paper on "The Paving of Roadways," and of the discussion, in which Messrs. Jas. Devonshire, Frank Trier, Percy Morris, and A. H. Pott took part. A notice is also given of the members' visit to the motor exhibition at Olympia, and of various other matters interesting to tramway and light railway men.

Wireless Telegraphy.—It is reported from Halifax that the Marconi Company contemplate another change in the site of their Cape Breton station. Representatives of the company have visited Lorne Head, near Louisberg, 25 miles from the present station, inspecting properties suitable for a site for the proposed new station. This would be the third change, as the second station, which is located at Glace Bay, four miles from Table Head, is about completed. A chief trouble with the Glace Bay station is that while messages can be transmitted from there, it is not possible with anything like equal facilities to receive. This is the point where failure comes in. It is thought that if a new station at Lorne Head is built it will be used for the reception of messages, while that at Glace Bay will be reserved for transmission. The cost of the first Table Head station was practically defrayed by the money given to Mr. Marconi by the Dominion Government of Canada when he first determined to erect Transatlantic stations in Nova Scotia. The present Glace Bay station has cost over £30,000. Nothing definite will be done until Mr. Marconi arrives.

Engineering Standards Committee.—We have received a copy of the committee's report on work in progress, which briefly describes the work of the committee from its inception in January, 1901, to July 31, 1905. The number of sub-committees has increased with the gradual development of the original single committee formed by the Institution of Civil Engineers, and there are now 35 sectional and sub committees. The whole work is supported by the five leading technical societies of this country and from H.M. Government, and there are serving on the different committees representatives from most of the technical societies and trade associations of this country. The Electrical Plant Committee is divided into three sub-committees—viz, generators, motors, and transformers; cables; telegraphs and telephones — presided over respectively by Colonel R. E B Crompton, Mr. R. Kaye Gray, and Mr. John Gavey, C.B. A great many matters have been under the consideration of these sub-committees, and at frequent intervals the Electrical Plant Committee have been called together to receive and consider their reports prior to their transmission to the main committee for final approval. Appended to the report is a list of members serving on the committees, together with a list of publications and templates issued.

Sand-Box for Tramcars.—An apparatus for the sanding of electric tramlines has been invented by Mr. Henry Liddle, of Newcastle. It is claimed for the invention that it will not only minimise the expense, but also the danger connected with the running of electric cars. The apparatus consists of a cast-iron box, made in two sections and bolted together. In the centre is a flat, perforated slide valve, working on parallel steel rollers. This valve is worked by means of a rod and crank, and brought to rest by the expansion or recoil of a spiral spring, the spring being encased in the sand-box casting, and kept in its place by a gunmetal bush, through which the valve spindle moves. In the upper section of the box is fixed an oblong bush with hardened knife-edge, the valve being so adjusted by adjustable roller bearings as to

Digitized by Google

be slightly clear of the bush. This bush communicates with the sand hopper on the car, and consequently when at rest the sand is always on the flat valve. As soon as the valve is set in motion, the perforation or porthole in the valve is open to admit sand to the lower section of the box, and through the sand-pipe to the lines. A sheet-iron plate is fixed by means of screws on either side of the box, which can be quickly removed, and the valve examined. These plates also serve to keep the rollers in position. Another feature of the arrangement is that on the deck of the car, communicating with the motorman's foot, is a fixed hinged step or crank, which can be thrown back inside a circular case when not in use, the idea for this being quick manipulation at both ends of the car in case of emergency.

Storage Batteries.—Within recent years the use of storage batteries for the operation of signal devices has increased rapidly. They were at one time employed xclusively for electric interlocking, but, as Mr. E. L. Adams points out in his paper read before the American Railway Signal Association, their use for automatic signals is being extended. At interlocking signals it is difficult to determine when the battery requires charging, but Mr. Adams's experience leads him to the conclusion that to have an adjustable resistance so connected that the main tainer can discharge the battery at its normal rate for a period of five minutes and to note when the voltage drops to a predetermined point, is the most reliable means of ascertaining. On automatic installations there are two methods in use—one where the storage battery is used to operate signals only, the primary battery being used on the track; the other where the storage battery is used on signals and track. When a signal system is so laid out that there are both single and double locations, it is a moot question whether the batteries at the single location will stand without injury twice as much charge as they are discharged. Mr. Adams considers that the use of the storage battery on a track circuit is its most natural application. On track circuits a constant current through the relay coils is desired, and the storage battery can provide this current, unless track conditions are exceptionally bad. Charging plants for both electric interlockers and automatic signal systems are, in most cases, operated by a gasoline engine belted to a generator of about 500 volts. There are cases where electric motors are used to drive the generators, but these cases are few, for most interlockers and charging stations are located at isolated points where a gas-engine is the only source of power.

Water-Turbines.—At a meeting of the members of the Northampton Institute Engineering Society on the 1st inst., Mr. W. Chappell read a paper on "Water Turbines as applied to the Generation of Electricity," in which he described the development of turbine building in Europe and America, and compared the cost of the turbine with that of an ordinary steam-engine. He estimated that the amount of water power available in the world is about 54 million horse-power, out of which only about two million horse-power is at present in use. He then dealt in detail with the various types of turbines suitable for the generation of electricity. In order to gain large power units at moderate falls, a number of turbines of the same design can be put on to the same shaft, whilst another type used for large power units where there is a great change in the fall, and where a large quantity of water is to be utilised, is the combined high and low pressure turbine which is in use at Chevres, in Switzerland. The efficiency of a water-turbine ranges from about 75 to 85 per cent. In a factory near Zurich measurements were taken, and the following efficiencies worked out at three-quarter load = 86 per cent., half load = 82 per cent., quarter load = 78 per cent. In order to get good efficiency, the revolving wheel must be small. Mr. Chappell then described the apparatus at work at the hydro-electric power station at Paderno, Italy, the electrical station at Chevres, and along the Niagara frontier. With regard to the comparative cost of water power and steam power, he claimed that the advantage of the former was really more than generally supposed. He estimated the expenditure of a dam and water carrier, which is generally made in the form of an open concrete channel or wooden trough, also a line of piping and the turbines to work out at from £2 to £3 per horse-power. The figures in the case of a steam plant and the land and buildings necessary for housing same work out to about £30 per horse-power. Running expenses, again, show in favour of water-power plant, which is about £2 per horse-power per annum more economical than steam plant, the cost of which works out at £4 per horse-power per annum.

Improvements in Trucks.—Mr. Elmer E. Cook read a paper before the members of the Tramways and Light Railways Association last night on "Improvements in Trucks," in which he dealt especially with those types designed to meet the wants of tramways and light railways. He pointed out that more attention must be paid by those engaged in the operation of building or equipping of tramways to the truck or bogie, which causes great discomfort to tramway passengers, and especially those who travel inside, when the type adopted is cheap or coarsely made. Discussing the standard types of electric traction trucks, he said that the only fault which could be found with them to-day is the lack of machining and fitting, and the same care in bolting together as in many of the other less important parts of the car. He attributed the cause of this state of affairs to the inexperience and conservatism prevailing throughout the tramway world, including the committees as well as the engineers and managers. The average life of this type of truck is about five years, but Mr. Cook remarked that a few extra pounds spent in assembling the various members would lead to a much longer life. He then presented a number of lantern slids showing some of the imperfections to which he referred in the paper. He said that the greatest improve ment made in the last six years in electric traction trucks was in the adoption of the radial type. In the opinion of Mr. Cook, it combines the best qualities of the ordinary single-truck car and the bogie or double-truck car, while excluding all the disadvantages found in either type. It can be adapted to any size of car, ranging from 14ft. to 32ft. In the case of the shorter cars, its first cost is about 75 per cent. greater than the ordinary rigid wheel-base truck, but where it displaces bogie cars the cost is not only less, but it gives a full track efficiency by the application of only two motors. In addition, it has not the destructive effect on permanent way. In the case of steel-tyred wheels, the flanges on the radial wheel may be thicker than upon the rigid wheel-base trucks. Another advantage of radial trucks is the saving of current, as its working principle has almost entirely obviated the friction at curves and turnouts. The truck has only been on the market for a very short time, but some 34 different undertakings have applied it, so that there are commercial possibilities before it.

Telephones for Locomotives.—In a United States consular report just issued, details are given of a wireless telegraphic device whereby the means of communication with engine drivers while trains are in motion are greatly improved. The device is known as the Pfirmann-Wendorf apparatus, and experiments covering a period of several months, carried on by the Prussian State Railway, are said to have proved uniformly satisfactory, even under the

Digitized by Google

most unfavourable conditions, due to rain, snow, fog, and darkness. These experiments were made on a specially-prepared track, several miles in length, extending from Goldstein to Sachsenhausen. Each locomotive used was supplied with a small Pfirmann-Wendorf apparatus, which, with its storage battery, occupies a very small space. Communication between this apparatus and the two track rails was supplied by the metal parts of the locomotive through the axles and wheels, while an insulated contact device connected the apparatus with a carefully-insulated auxiliary rail running midway between the track rails, the contact device being so arranged that it could easily be moved back and forth or sideways. Positive and negative charges can thus be sent in different directions, frequent changes being made from one rail to another. If there is an obstruction of any kind within a certain distance, an alarm is thus given, both visibly and audibly, by means of a red light and by the ringing of a bell. Engineers, signalmen, and stationmasters can thereupon communicate together by telephone, the central auxiliary rail serving as the channel of communication. In each locomotive there is a telephone, which is protected against the vibrations caused by the motion of the locomotive through being fastened on springs. In like manner, in cases of sudden danger, track guards can transmit a warning to the engineers of approaching locomotives. If for any reason a storage battery becomes exhausted it can be replenished with electricity produced by the locomotive, and even if this supply fails the current from a semaphore or signal station can still transmit to the engineer explanations and instructions. If by mistake a semaphore falsely registers a clear track, the endangered trains nevertheless supply each other with signals of warning. An alarm is also given automatically when a switch is falsely set or insecurely closed. The auxiliary line may be of ordinary T iron or of old rails, as desired.

Wireless Telegraphy and Submarine Cable.—The submarine cable situation in Alaska, which is complicated by the failure of wireless telegraphy, has brought forth an expression of opinion on wireless telegraph problems from Major W. A. Glassford, chief signal officer of the department of Columbia. He said that one of the claims made in behalf of the wireless service was its adaptability to that section, because it would span over the physical difficulties encountered by the present land wires. In combating this view, Major Glassford said that the Signal Corps were to-day operating the longest successful wireless system in the world between St. Michael and Safety Harbour, a distance of 107 miles. This plant was evolved and installed by the Signal Corps, and would naturally meet with any improvements or extensions, if such were possible. The mere fact that the chief signal officer of the army, after a personal visit to Alaska last year, did not recommend the installation of the wireless plant demanded by the Alaskan papers shows that he found such extensions or improvements were not possible. On the contrary, an extension of the cable and land lines will doubtless be recommended. It has been shown, said Major Glassford, that a single stretch in wireless communication is quite possible, but a chain of them has not so far been accomplished. Even though the wireless installation of the Signal Corps might be extended 107 miles or more overland there would be objections, and possible insurmountable difficulties in establishing a chain over so long a distance from St. Michael to Valdez, which in a straight line is between 500 and 600 miles, but with a chain of stations would be in the neighbourhood of 1,000 miles. There has not been discovered so far any means by which a message can be sent and one received at the same station at the same time, and the consequent delay would be considerable. It is, therefore, clear that, even though great improvements have been made in the wireless telegraph, it could not handle the volume of business that would be given to it as is now transmitted by the telegraph, so that under the circumstances it is not surprising to find that in his annual report to the department, Major Glassford strongly recommends that the earnings of the telegraph service should be applied entirely to extensions and improvements of the system and to the laying of additional cables. The fact that this recommendation receives endorsement from General Constant Williams, in command of the department, points to the likelihood of its adoption. In fixing the above limit of distance to wireless telegraphy, Major Glassford was evidently influenced by his own experience with certain apparatus. These conclusions do not apply generally.

Association of Technical Institutions.—The council of the association have just completed an inquiry into the co-operation of employers with technical institutions for the technical education of their apprentices, and the results of the inquiry have been published in the form of a report. The idea of holding such an inquiry originated at the annual general meeting of the association, when two papers on the subject were read and discussed. In the first place, a form of inquiry was sent to the 65 institutions affiliated to the association and to technical institutions not affiliated to the association. As a final step in the inquiry, information was sought from some of the large employers of labour whose educational work with their employés was not likely to be connected with the various technical institutions already approached, and several of the replies received from all sources have added valuable information on the subject. It is evident that a large number of employers of labour are co-operating with technical institutions in encouraging the attendance of their workers at evening classes. At the Barrow works of Messrs. Vickers, Sons, and Maxim, Limited, it is one of the rules of admission that all apprentice lads are advised to become students at the local technical classes, and, providing satisfactory evidence of their attendance is given, the apprentices may, as vacancies arise, compete for entry into the drawing office. Students are also granted a reduction in the number of working hours, while rewards in the shape of increased pay, bonuses, and preference are also held out to them. Two large engineering firms in the neighbourhood of Birmingham are considering their terms of apprenticeship, so as to make the progress of their apprentices dependent (in conjunction with other things) on progress at afternoon and evening classes at the municipal technical school. A number of engineering firms in Bolton offer scholarships to their apprentices, tenable at evening classes, in science and technology. In Bradford arrangements have been made between the Engineering Employers' Federation and the Technical College Committee for an efficient course of instruction to apprentices. One firm in Edinburgh, which charges no premium to its apprentices, requires them to attend evening classes, and at the end of three years, if sufficiently qualified, they are allowed to attend the day college for two winter sessions, the summer months being spent in the works, while in Glasgow the scheme whereby apprentices are allowed to spend part of their time at college and the other part at the works has been for many years in operation. Though the report does not profess to be a complete one, it is sufficient to indicate the useful purpose which such an association serves in bringing about more co-operation between employers of labour and technical colleges.

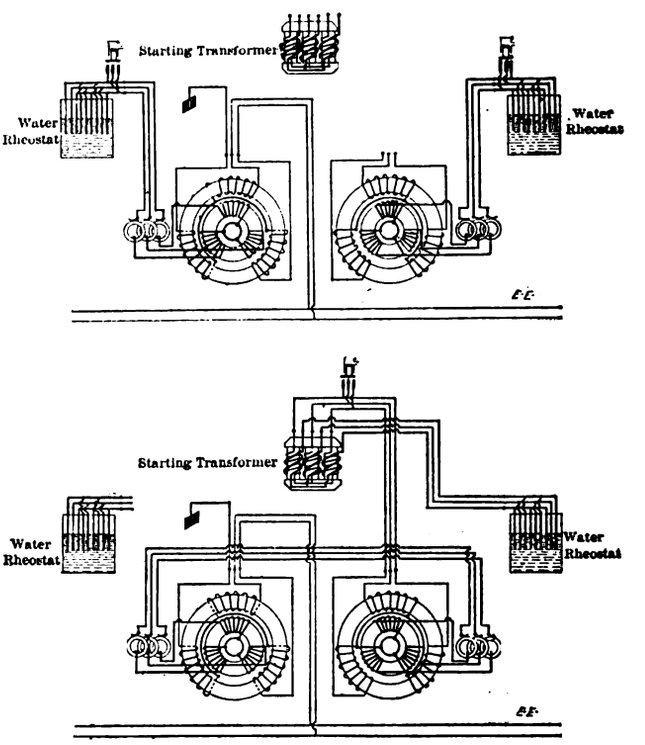
Rubber.—A great deal of activity is manifest in financial quarters for the acquisition and cultivation of rubber fields, and two new rubber companies are being promoted to work rubber estates in Ceylon and Liberia. There is no doubt about the profitableness of an investment in a rubber concern, provided, of course, that the undertaking is perfectly *bonâ fide*, as in this case we have no reason to suppose otherwise. The trees are known to yield a profitable return within five years of planting, while they seed abundantly in much less time. As Mr. H. A. Wickham pointed out in our columns in 1902 (vol. xxix., p. 42), the Hœvea is a large tree, which under favourable conditions attains a girth of 12ft. in the bole. It is most favourably planted and cultivated at a distance of 33ft. by 33ft., 40 to the acre, and giving, say, 5lb. of rubber per tree at 3s. per pound, it would yield at the rate of some £30 per acre for the sale of rubber alone, quite apart from the value of the seed crop, to be converted into oil worth £25 to £30 per ton. The Rubber Estates of Ceylon, Limited, whose prospectus has just been issued, will have some 1,200 acres under rubber at Dec. 31, 1905, and before the end of another 12 months a further 1,100 acres should be planted, which, together with the opening out of the remainder of the forest, should give a total of 3,200 acres under cultivation in parts of Ceylon which are considered by experts to be very favourable for the purpose. The directors estimate that a rubber yield of 1lb per tree, or 200lb. per acre, selling at, say, 3s. 6d. per pound net (whereas the present selling price is over 6s.), and costing 1s. per pound to produce, would give a profit of £25 per acre. This fully bears out the contention of Mr. Wickham that it is more advantageous to plant only 40 trees to the acre, each yielding 5lb. of rubber, for, apart from other considerations, there would be a saving in labour which the planting of 200 trees to the acre would necessitate. The Liberian Rubber Corporation, Limited, is being floated with a capital of £270,000 to take over from the Monrovian Rubber Company, Limited, a concession of about 2,800 acres in the Republic of Liberia. Sir Harry H. Johnson, late consul-general in Uganda, who is chairman of the company, in his report to the directors, states that the collecting stations, which now number four, can be immediately increased to 30, and the output of rubber can be increased to about 500 tons a year, which would give a net profit of £65,000 per annum, taking the present price of rubber as a basis. He estimates that within six years there will be 2,300,000 cultivated rubber trees yielding African rubber of excellent quality at a price of at least 4s, which should leave a profit of 1s. per tree per annum. It will be seen that the methods of working and calculations of the two companies are by no means identical, but is evidently impossible to make adequate comparison between the two, as the Liberian territory consists of vast primeval rubber forests. Both companies are launched under most favourable auspices, so that the outlook seems bright.

Heavy Electric Railroading—Mr. Bela Valatin contributes an article to the *Electrical World and Engineer* in which he deals with the problems of electric traction by the use of other than direct-current methods, which has been found disadvantageous. There are now three competitive systems—the direct-current, the single-phase, and the three-phase—and it is possible that each will find adoption in particular cases. The author makes a comparison of the three systems, with results favourable to three-phase current. The principal points which enter into electric traction for main-line railway service, and which determine the choice of any particular system, comprise the amount of capital outlay, the economy of operation, security of service, and flexibility of the system to meet the special requirements of traffic on a main-line railway. We have already referred to the Valtellina three-phase railway (particulars of the equipment and results of tests were given recently). With the newest type of locomotive used on this system, by means of a connecting rod the axle is driven at the same number of revolutions as the motor. By this new method an advantage is gained over the direct coupling of the motor to the axle, in that the motor is made independent of the locomotive axles and wheels. The mechanical efficiency of this new method is very high. Tests have shown that the use of connecting rods does not increase the friction losses over those due to direct connection. Mr. Valatin has prepared a comprehensive table giving a comparison of the weights of electric railway motors, from which it is observed that the weight factors of the polyphase motors indicate that these machines give the best output for the amount of material used. He points out that for the construction of large motors with a low number of revolutions, the three-phase motors are specially well suited owing to their ability of better utilising the space, inasmuch as the collector rings can be placed outside



the frame, whilst the weight of the three-phase motor is less than that of the direct-current. The reduced efficiency, the corresponding increased losses, the larger commutator, the pulsating magnetic field, all cause the weight of the single-phase motor to be greater than that of the direct-current motor. To the assertion that the reduced weight of the three-phase motor has been obtained at the cost of security, Mr. Valatin replies that the results of actual experience on the Valtellina system, where the bearings of the motorcars have been in service over 125,000 miles without requiring replacing, is proof of their security. There is no difficulty in using all motors in parallel under high tension by the application of the cascade regulation, which is used principally to allow the ascending grades at a decreased speed, and to ensure a higher economy at starting. The diagram shows an arrangement by which both motors can be used under high tension and work in parallel at high speed. In cascade connection, a transformer is put in circuit between the starting rheostat and the high-tension side of the secondary motor. This transformer is used only when starting, and it does not influence

Digitized by Google

the economy, inasmuch as the transformer losses simply replace a part of the rheostat losses. With reference to the operating cost, the energy consumptions of each of the three systems have to be considered, as has also the number of stops on the line. Another consideration is whether the energy transmitted to the moving trains on down grades must be mechanically braked, or can be returned to the line to be used by other trains. The recuperation is of special importance when the returned energy can be used immediately; this would be the case where there is a dense traffic, or where the central station is also called upon to supply energy for other purposes than the moving of trains. The experience on the Valtellina line shows that the recuperation on light down grades is used to advantage, even though no other train is simultaneously on the line to absorb the same. The existing installation of three-phase roads have fully proved, says Mr. Valatin, that the two-wire high-tension equipment fully conforms to the most severe exigencies for safety of service demanded by the important traffic of a main-line railway, and the experiences on the Valtellina have shown that the safety of service and durability of construction of the overhead equipment depend on the suitability of the current collector. Mr. Valatin concludes by saying that for heavy electric traction the three-phase system is far superior to all others. If the single-phase system had not the advantage of requiring only one wire, instead of the two used by the three-phase, it would not be considered at all. Against the advantage of the single wire there must be placed the lower installation cost, smaller weights of motor-cars or locomotives, greater security of service, and less cost of maintenance on the side of the three-phase. In time these advantages, he says, will cause the present prejudice to be overcome.

Institution of Electrical Engineers.—The seventeenth annual dinner, which was held at the Hôtel Cecil last Friday night, brought together a fine constellation of *savants* and distinguished representatives of the engineering professions. Mr. John Gavey, the president, was in the chair, and among the guests were Lord Strathcona, Major-General Sir A. E. Turner, Sir Joseph W. Swan, Colonel R E. Crompton, C.B., Sir George Murray, Sir Alexander Binnie (president of the Institution of Civil Engineers), Prof. Dr. E Budde (president of the Verband Deutscher Elektrotechniker, Berlin), Sir Norman Lockyer, Mr. C. E. Spagnoletti, Mr. R. Kaye Gray, Mr. James Swinburne, Sir J. C. Lamb, C.B, Sir Charles Owens, Colonel Sir H Jekyll, Dr. R. T. Glazebrook, Sir A. B. W. Kennedy, Mr. H. Babington Smith, C.S I. (secretary of the General Post Office), and the Hon. J. G. Maydon (Minister of Railways in Natal). After the loyal toasts had been duly honoured, Mr. Babington Smith (in the absence through indisposition of Mr. R. W. Perks, M.P) proposed "The Institution of Electrical Engineers." He said that the only reason he could think of for being called upon was that he was the representative of their oldest and one of their best clients. One of the originators of the Institution was the late Captain (afterwards Major-General) Webber, who for many years was connected with the telegraph service of the Post Office. The past-presidents of the Institution included some eminent men connected with the Post Office and they had now their present engineer in-chief, whose election was received with great satisfaction by his colleagues. The President, in reply, said he could scarcely conceive that such enormous progress had been made in electrical science and industry in the last 50 years. He remembered the time when the only representatives of electrical engineering were the telegraph engineers. When the units had been laid down by English manufacturers, they were legitimised by Europe and became international units. He said the electrical engineer had invaded every industry, and where he had intervened he had increased the output and reduced costs. He thought that in the immediate future the engineer, whatever his speciality might be, would have to include in his curriculum a thorough knowledge of electrical engineering. Sir Alexander Kennedy, in proposing "The Electrical Industries," said no great industry had ever built so satisfactory a superstructure on so sound a foundation financially as the electrical industries had done in the course of the very few years which they had taken to attain their present growth. There could hardly be any industry which had to keep itself, and had kept itself, so intimately in contact with the latest experiments, theories, and discoveries of physical science, and he even went so far as to say there was no industry which had ever done so much, although it was a manufacturing industry, towards the advancement of the very science upon which it was based. The industry, he said, was healthy from the commercial point of view, and success from the commercial view meant success all round—even in Westminster. In coupling with this toast the names of Mr. E. Cunliffe Owen and Dr. E. Budde, he said he hoped the latter had not come to reproach them for stealing from Berlin Prof. Kapp, but now they had him they were going to stick to him. At the same time Dr. Budde could take back with him the knowledge that English electricians looked upon his countrymen as their very good friends. Mr. E. Cunliffe Owen, C.M.G., in responding, said that the recent exhibition at Olympia was a success, and resulted in a surplus. They intended to set apart a certain amount for the newly-instituted benevolent fund of the Manufacturers' Association, and they also intended to make a grant to the benevolent fund of the Institution of Electrical Engineers to the amount of £250. Dr. Budde also responded, and at the outset delivered to the Institution the greetings of the German electricians, whom he represented. The Institution had been the first to go abroad and inspect foreign works and doings, and he assured them that their invitation to foreigners to visit them in return would be highly appreciated. He asserted, with warmly-expressed sympathy of his audience, that the contact between scientific and technical men could not be too close. Research and intellectual labour form a tie which draws together the best in the world. German electricians looked with joyful admiration on the great men who stood out from the ranks of their English friends and the imposing results they had achieved. The scientists of the Fatherland were ever ready to join in advancing the international solidarity of science and technics, and in so doing to do something to sink race differences. Mr. Alexander Siemens proposed "The Colonies," which, he said, were connected to the Mother Country by submarine cables, so that electrical engineers had done a great deal towards consolidating the Empire. This toast was ably responded to by the Hon. John G. Maydon. The last toast of the evening, "Our Guests," was proposed by Mr. W. M. Mordey, who particularly welcomed the railway men, from whom they expected a great deal. They had encroached upon their preserves, but they hoped to do so still more in the future. He seriously advised them to place themselves in the hands of the electricians. He acknowledged the debt of gratitude which the Institution owed to the Civil Engineers for lending them their hall, and he coupled the toast with the name of Sir Alexander Binnie, president of the Institution of Civil Engineers. In reply, Sir Alexander declared that electricians had conferred inestimable benefits on mankind by bringing into more intimate relationship the different peoples of the earth, and by so doing wearing off the rough edges of nationalities.

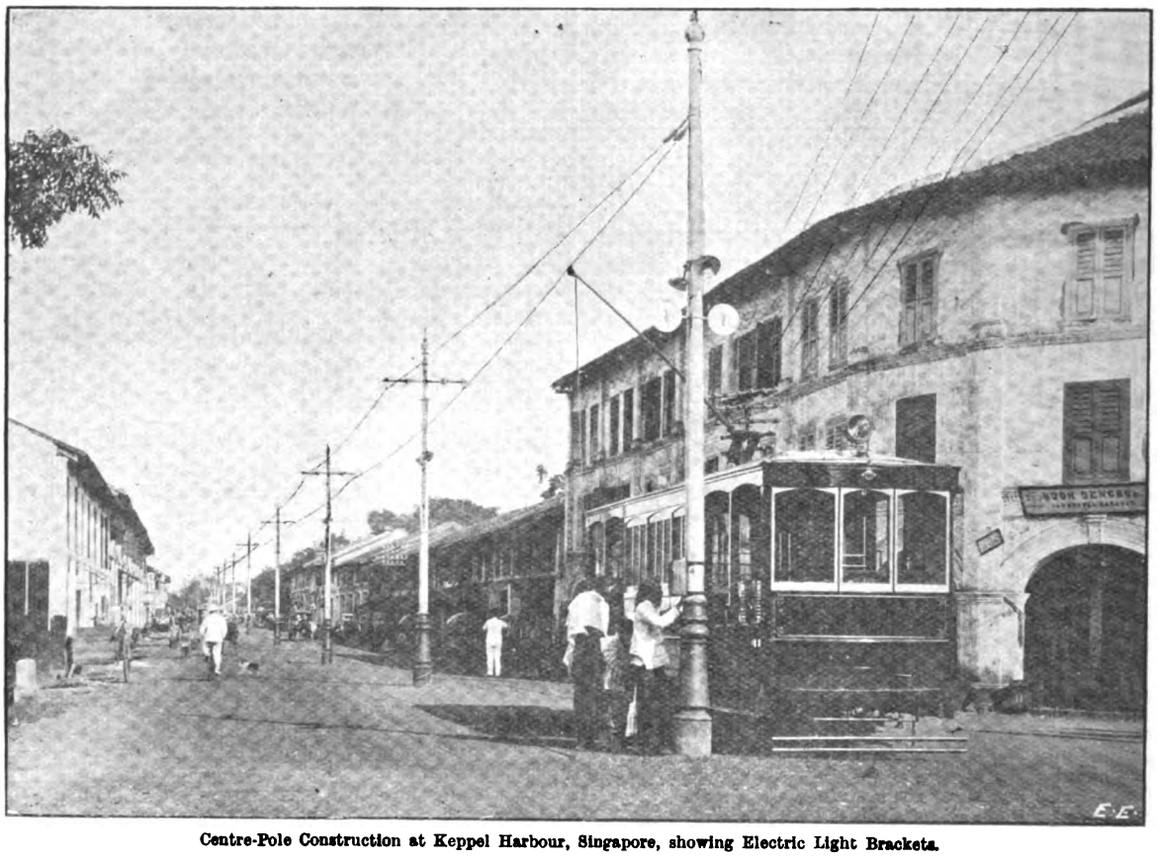
ELECTRIC TRAMWAYS IN SINGAPORE.

The newly-equipped tramways in Singapore may, with the exception, perhaps, of that thriving enterprise in Calcutta, safely claim to be the largest and most up-to-date system east of Suez. The buildings in Singapore, like those of other places in the Far East, range from substantial brick and stone structures to rudely-made huts of the native Malays. From the illustrations given herewith it will be seen that the streets are for the most part broad, straight, and level, thus being admirably adapted for electric tramways. The total population is approximately 250,000, which, besides Europeans, includes Eurasians, Chinese, Malays, Indians, Japanese, and many others. The climate of Singapore is tropical. The town being almost on the equator, there is very little variation in temperature all the year round. The effect of this on the vegetation is most marked. Palms, cacti, fruits, and flowers flourish in abundance, and, except where clearings have been made for buildings or agricultural purposes, dense jungles are still in existence, affording as safe a home for their denizens as do the jungles of adjacent Burma.



Centre-Pole Construction at Keppel Harbour, Singapore, showing Electric Light Brackets.

The city of Singapore (or Sincapore) was founded in 1819 by Sir Stamford Raffles, and it is owing to his sagacity that the happy choice of Singapore was made as the site of the present flourishing commercial emporium for British trade in the East Indies. In 1824 the British Government by treaty purchased from the then resident officer or chief, called the "tumangong," for 60,000 Spanish dollars (£13,500) and a life annuity to the Sultan of Jahore, and his resident officer of 24,000dol. (£5,400), the sovereignty and fee simple of the island, as well as all the seas, straits, and islands to the extent of 10 geographical miles around. In 1830 it was made the capital of the Straits Settlement, superseding Penang, and to-day it is undoubtedly the most important trading centre in the South-East of Asia. Its geographical position, combined with its splendid harbour, adds to it further importance as a port of call for steamship lines trading between Europe and the Far East.

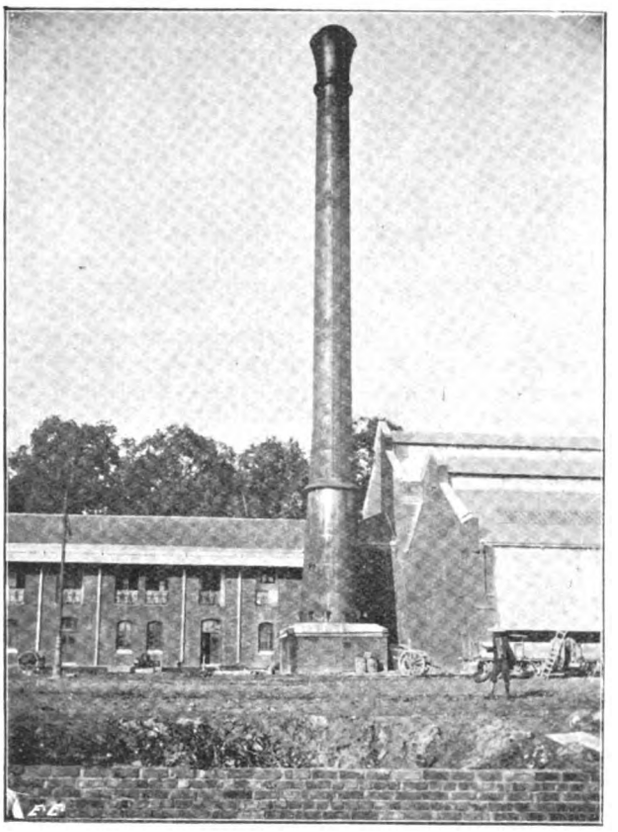
The construction of the tramways was authorised by an ordinance passed by the Legislative Council of the Straits Settlements in 1902 The promoters of the scheme were the Association General, Limited, London, and the East India Construction Syndicate, Limited, London, was formed for the purpose of carrying out the construction of the tramways. The consulting engineers to the company are Messrs. Alfred Dickinson and Co., of Birmingham and London, who prepared all the detailed plans and specifications, and superintended the carrying out of the work. The contractors for the whole of the work, which included the construction of a bridge over the Kalang River, were Messrs. Dick, Kerr, and Co., Limited, of London and Preston. The work was commenced in July, 1903. and the first section of the line was opened for traffic in July, 1905.

The total length of the tramways is 16 miles of route, the length of the single track being about 26 miles 4 furlongs. The track is laid to a gauge of 1m., with rails of the girder type weighing 95lb. per yard. The rail joints are welded by the "Thermit" process, so that the track forms one continuous length. During the initiation of the scheme considerable discussion took place as to the advisability of having welded joints, the question at issue being, of course, the variation in the temperature. It was finally decided, however, that this difficulty was of too slight a nature to affect the joints after having been securely welded together by this special process. In addition to the Thermit joint a single 6/0 S.W.G. copper bond is supplied at every joint, thus ensuring perfect electrical conductivity.

The lines in the centre of the city, and those running to the docks, are for the most part double-track centre-pole construction, while the two routes leading north and north-east along the Serangoon and Gelang roads respectively are single lines with passing places, and are equipped with side-pole construction. Commencing near the entrance to the Keppel Docks, the route of the tramway follows Telok Blanga-road, past the entrance of the P. and O. Company's Wharf, passing the extensive wharves of the Tanjong Pagar Dock Company, to the junction of Anson-road and Tanjong Pagar-road, where it divides, one route following Anson-road, Cecil-street, and terminating on Collyer Quay, opposite Johnston's Pier, the other following along Tanjong Pagar-road, South Bridge and North Bridge roads, a portion of Victoria-street, and thence along Gelang-road to within a short distance of the bridge over the Gelang River. The route leading north commences near the Raffles Hotel, then follows Bras Bosah-road, Selegie-road, and Serangoon-road as far as the municipal boundary, where it terminates. A loop line is laid along Lavender-street, thus joining the

Digitized by Google

routes along the Gelang and Serangoon roads. There is also a short route which commences at the junction of North Bridge-road and South Bridge-road, and follows High-street, New Bridge, River Valley-road, and Tank-



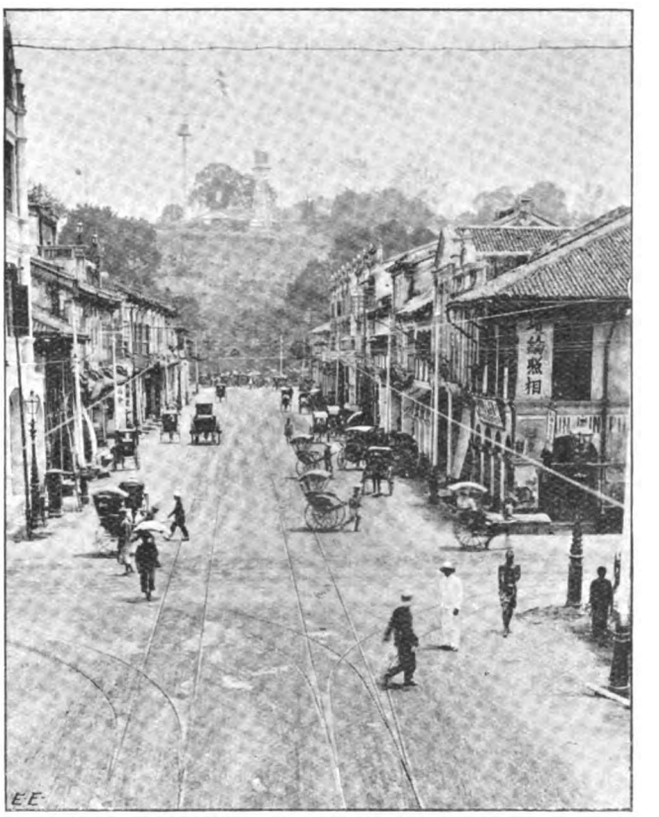
View of Chimney at the Singapore Power Station.

road, terminating near the station of the Singapore-Kranji Railway in the latter road.

The permanent way throughout is of a very substantial construction. The rails are laid on a longitudinal concrete sleeper, 8in. deep by 18in. in width. The flange of the rails is embedded in the concrete to a depth of 2in., and consequently there is a solid bed of concrete 6in. deep under the flange of the rails. The gauge of the track is maintained in the usual manner—*i.e.*, tiebars are spaced 8ft. apart throughout. After the rails and concrete foundation were laid, the road surface up to the rail-level has been

High Street, Singapore, looking up North Bridge Road.

made up with macadam, rolled and consolidated in the usual way. The overhead construction consists principally of side and centre pole construction, and also some two miles of span-wire construction. The poles are of mild steel, 28ft. 3in. in length, 7in. in diameter at the base, tapering to 4in. in diameter at the top. They are set 6ft. in the ground, and are embedded in a solid block of concrete, each pole being provided with an ornamental cast-iron base. On the centre poles the lengths of arms are 2ft.,



An Important Crossing on the Singapore Tramways.

while those on the side poles vary in length, according to the distance from the pole to the track. The trolley wires, which are not necessarily over the centre of the track, the possible variation being about 10ft., are divided into half-mile sections by means of section insulators. At each of

A Street in Singapore, showing Tower Wagon for erecting Overhead Work.

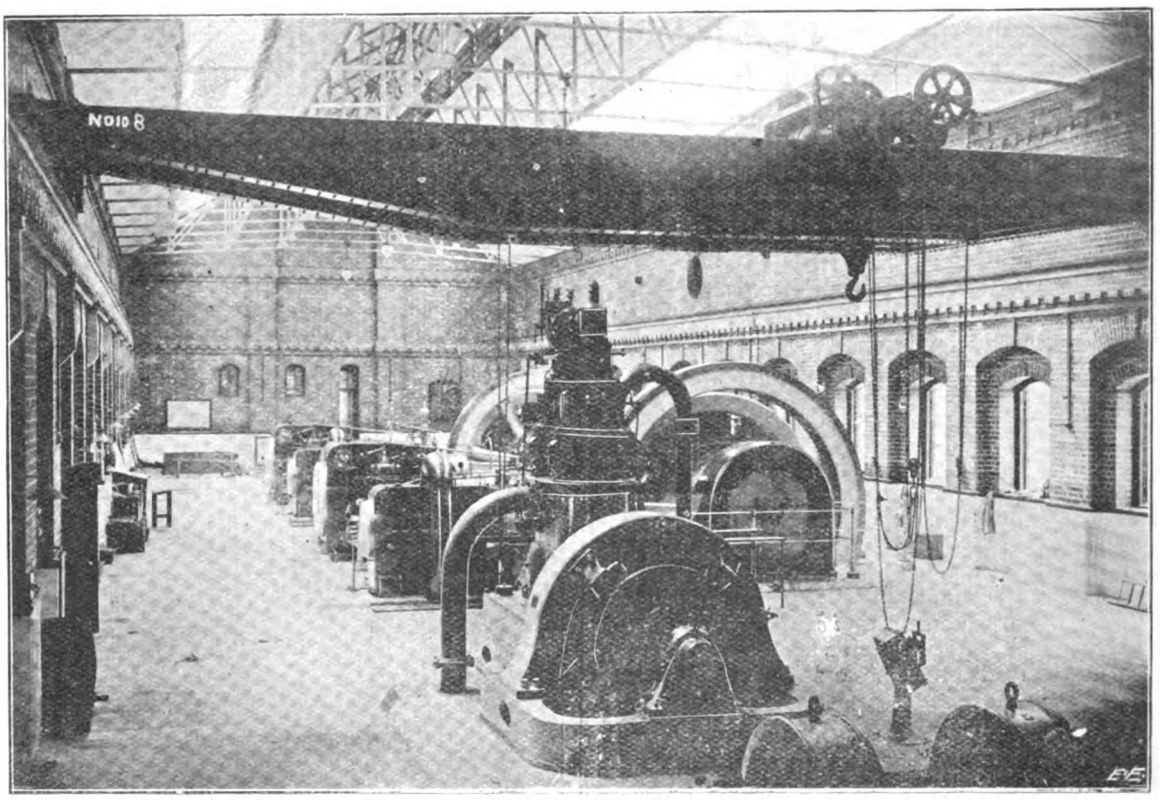
these points the main feeder cables are tapped and current is conveyed to the trolley wires by means of $^{37}/_{16}$ rubber-covered cables, which are carried up the inside of the poles and along the side of the bracket arms. The pressure on

Digitized by Google

the trolley wires is 500 volts. A lightning arrester is provided in each section pillar, as is also a telephone giving direct communication with the power-house; and to guard against the tropical storms, which are so prevalent in Singapore, the overhead system is additionally protected by heavy lightning arresters at every half-mile of wire—these are fixed on the poles in cast-iron boxes, and are connected directly to the trolley wire. The whole of the feeder cables were supplied by Messrs. Callender's Cable and Construction Company, and laid by them on their solid bitumen system. The system of feeders has been arranged with due regard to future requirements, as it is generally anticipated that within the near future the traffic will rapidly increase, both as regards passengers and the conveyance of goods.

The generating station and car-shed occupy a most desirable position near the Rochore Canal, from which water is obtained for condensing purposes. The depôt buildings comprise the engine-room and basement, boiler-house, car-shed, machine shop, carpenters' shop, paint shop, smithy, offices of the general manager and his staff, and the usual outbuildings. The engine-room is 190ft. long by 48ft. 9in. in width, and contains two main traction 500-kw. sets, one steam lighting set, one motor-generator lighting set, and the necessary switchgear. The boiler-house contains eight Lancashire boilers, arranged in two batteries of four boilers each; each boiler is capable of evaporating 6,000lb. of water per hour, with a working pressure of 175lb. per square inch. Feed water is supplied to the boilers by four feed pumps, two to each battery; these are of the duplex compound non-condensing type, taking water either from the hot-well or storage tank. There are two Green's economisers, each containing 228 tubes, one being situated at either end of the boiler-house. The main traction engines, of which there are two, were built by Messrs. Yates and Thom, Blackburn, and are of their well-known horizontal cross-compound condensing type, running at 100 r.p.m., and are each capable of giving a maximum output of 927 b.h.p. per minute with a steam pressure of 165lb. per square inch at the cylinders. Each engine is provided with a Worthington surface condenser, but may be worked either condensing or non-condensing. In order to leave the engine-room as free and open as possible, it has been arranged so that the condensers are fixed to the basement constructed below, as are also all the steam-pipes and other usual accessories.

The generators were built by Dick, Kerr, and Co., and are of their continuous-current multipolar type, compound-wound. Each machine is designed to give an output of 500 kw. with a pressure of 550 volts when running at a speed of 100 r.p.m. Each generator is direct-connected to the shaft of the engine, and is designed to run separately or in parallel. They are in every respect in accordance with the firm's standard practice. The magnet frame is of cast iron, the pole-pieces being built of laminated steel and cast into the magnet frame. The commutation is sparkless at all loads, and the windings are so arranged as to give a 10 per cent. rise in the EMF. from no load to full load. The lighting sets are for lighting the city and depôt by means of incandescent and arc lamps, and consists of one 150-kw. Dick Kerr generator running at a speed of 350 r.p.m. to 400 r.p.m. The dynamo is designed for use either as a compound or shunt machine, and is coupled to a Willans triple-expansion condensing engine with extension base. Also a 50 kw. Dick-Kerr motor-generator set, shunt wound, designed to give a normal output of 100 amperes at 500 volts and a maximum of 115 amperes at 550 volts, and two balancers of the same firm's make, for use in conjunction with the above lighting dynamos, for 500 volts pressure.



View of Engine Room, Singapore.

The switchboard was built by the contractors, and is composed of 15 panels, each supported independently on an iron frame. The board consists of a main station panel, two generator panels, five feeder panels, one Board of Trade panel, and six other panels for lighting, etc. The chimney stack, which is of steel, is 135ft. in height and 7ft. internal diameter, and is a notable landmark for many miles around. The base of the stack is built in a substantial manner, and is finished square on the outside, massive stone blocks being provided at top of base to form the foundation for the circular part of the chimney.

The car-shed is 212ft. in length by 138ft. in width, and is built to accommodate 84 cars. Inspection pits run the entire length of each track, with the exception of the curves at the entrance to the shed.

The rolling-stock consists of 50 passenger cars, three bogie motor goods vans, 15 four-wheel goods vans, and 15 four-wheel goods wagons. The passenger cars are divided into two distinct types, 30 being of the single-deck, single-truck, open type, to seat 32 passengers; and 20 single-deck, single-truck combination type, to seat 40 passengers. The whole of the rolling-stock was built for Messrs. Dick, Kerr, and Co. by the United Electric Car Company, of Preston, and is in every way up to this firm's

Digitized by Google

usual standard. The car bodies are mounted on Brill 21-E trucks, and each are equipped with two of the well-known D K. 25B traction motors. The motors are of the four-pole, series-wound, single-reduction type, and are suspended on bearings 4in. in diameter. They are designed to work at a pressure of 500 volts, and are capable of giving for one hour 25 b.h p. when running at a speed of 570 r.p.m, the temperature not rising above 110deg. F. in excess of the surrounding atmosphere. The controllers are of the same firm's standard D.B. 1 form "C" patent metallic shield blow-out pattern. They are of the series-parallel type, and are so designed as to give an easy acceleration to the car and an equal division between the two motors driving the various combinations. The cars are fitted with Hudson and Bowring lifeguards. The three bogie motor goods vans are each mounted on Brill 27-G trucks, the equipments being of the D K 25B quadruple type, with the D.B 1 form "C" controllers. They are intended for use of a double purpose, that of conveying goods and hauling goods trucks, the general arrangement of the body being such as to provide a self-contained van with divided sliding doors on each side, which may be securely locked up, and a vestibule canopy at each end as the platform for the drivers. The 15 goods wagons are equipped in a similar manner to the passenger cars; they are 12ft. in length and 6ft. 6in. in width. These wagons are for general use for the conveyance of various classes of goods up to six tons in weight; the frame is made of mild-steel channels, stayed by longitudinal and cross stays, knees and gusset plates; the side of each wagon is provided with strong hinges. In order to protect the goods from the weather, each wagon is supplied with a detachable light angle-iron frame, upon which a tarpaulin is spread the full length of the car at a height of 7ft. from the flooring of the wagon. They are in construction similar to that of the goods wagon as described above. Each van is fitted with double sliding doors, and is the same size as the goods wagon.

ELECTRICITY AS A HOME COMFORT*

BY J. D MACKENZIE.

When your secretary wrote asking me to address you on electric lighting, and in so doing to take the place of a gentleman whose name is so well known in electrical circles, I felt a great deal of diffidence in accepting, and that for several reasons. But principally because, as you are all aware, everyone nowadays knows everything about electric lighting. In these days of general illumination—mental, not material—what with free libraries, halfpenny-a-day encyclopædias, sixpenny books on electric light and how to make it, and last, but by no means least, the super-technical magazine article writer, there is really nothing left for the like of me to speak about; or, at least, gentlemen, there ought not to be. Why? I'll tell you in all confidence, even little Tommy-six-year-old-last-July and the gasfitter round the corner know all there is in it. And so no doubt you can understand with what reluctance I had to face the task of giving you "cauld kail re-het." Borne up, however, by the thought that some of you, perhaps, may be still—shall I say—unsophisticated enough not to place all your confidence in the aforementioned sources of information, and that a humble disciple of Volta and Faraday, Hopkinson, Kelvin, Edison, and Swan—men whose names are blazoned on the page of history—may be able to give you at least a plausible excuse for a discussion—borne up by that thought, gentlemen, I am here to-night.

The subject of the following few remarks is "Electricity as a Home Comfort." A strange title, perhaps, and yet it is stranger, when you come to think of it, how comprehensive that title really is. For, if you wish electricity to be a home comfort, it must (1) be well planned and (2) well carried out. And what more can you—can anyone—possibly want and so my remarks this evening shall be comprehended under these two main topics: (1) the design of electrical arrangements; (2) executing design. And, just in passing, may I add that many a time when executing some of the designs submitted to us, we would feel quite happy if we were assisting at the execution of the designer. Now, in designing any electrical arrangement several things must be considered: (*a*) the purpose in view; (*b*) the ease or difficulty of carrying into effect; (*c*) accessibility for repair; (*d*) the effect of each part of the arrangement on its immediate surroundings; (*e*) the general effect of the whole arrangement. The most of the following remarks deal with electric lighting, but, as the title is quite general, a few words on other applications may be said at this stage.

Bells.—Here the purpose in view is to give an audible signal that attention is required at a certain point, and such signal may or may not be accompanied by a subsidiary visual sign. Now, in a private house, when you have accomplished this object—when you have given the signal—with as little noise as possible, your purpose is achieved; there is no necessity for installing a bell which will sound and resound through every nook and cranny of your dwelling on the slightest provocation. In doing so, you have overstepped the limit, and "Electra" is a home comfort no longer. But, you say, a bell in the kitchen is no good when the servants are upstairs. Granted! But place another gentle reminder upstairs; better far that you should hear in more than one place the soft "tintinabulation of the bells—silver bells," than be doomed by a cruel fate and your architect to listen to the

> "brazen bells, ...
> How they clang and crash and roar!
> What a horror they outpour!
> On the bosom of the palpitating air."

Pushes are used for actuating the "bells," and it is quite as easy to get a push ½in. diameter to be as effective as the "3in. best cocus push with best German-silver springs and platinum contacts" of the average specification; and the former has this advantage over the latter, that it can be concealed in some neat little corner, and not, like the other, be continually glaring at one with its cyclopean countenance.

Telephones of the miniature variety are now so often installed in the homes that I must not pass them by without comment. They will just achieve their purpose quite as effectively when hid in a corner cupboard or below a shelf on your mantel-piece as they do when spoiling the symmetry of your panelled walls. And if you, personally, do not object to their appearance, have mercy on your friends to whom the sight brings vivid memories, if not of a "disembowelled hurdy-gurdy," at least of business worries and work, from which they wish for an evening to rid themselves.

Electric Heating.—Here there are several cases requiring very different treatment. If one intends to use electric heating on any large scale, it is important to design special circuits for such, so as to take advantage of the special cheap rates given by corporations and supply companies. The various purposes to which the heating property of the electric current can be applied are so numerous that I can only glance at the subject. But just to quench the ardour of my gas friends while yet there is time, may I say that I believe gas to be the proper medium for general heating purposes in the like of larger cities where gas is very cheap. But for country houses having no gas plant, but with their own electric supply, there is no reason why electricity should not be used throughout, and be quite economical at that. In the laundry it might be used with advantage to iron one's linen, and is really not so very expensive in upkeep, while the fact that cleanliness is increased to a maximum and risk of fire reduced to a minimum, and that your laundress is not half asphyxiated with the noxious vapours from coal gas, ought to go far to outweigh any disadvantages on the score of cost. In the public rooms, not only does one wish the heating effect, but also some of the warm glow which, from custom, we associate with fire, and hence one wants, in such rooms, radiators of the incandescent lamp pattern; and here I must confess, notwithstanding electricity, I have a most decided sentimental partiality for the old-fashioned log fire, or even for a good peat or the more prosaic coal one, and relish nothing better than to sit in the gloaming watching the fitful glow of the

* Paper read before a Glasgow Engineering Society.

Digitized by Google

flame playing among the logs and casting long and weird shadows through the room.

Such, however, is not the most efficient way to get the greatest heat value out of the fuel. But to return to electric radiators. The purpose is to give heat, and although it may be much more effective as far as appearance goes to place the radiators on the earth or into the interior of the fireplace, unless provision is made for closing the flue effectively, the heat, instead of being radiated through the room, is sent uselessly up the chimney. There seems no reason why niches should not be left in some of the walls suitable for the reception of such radiators, where they would be out of harm's way when not required. In bedrooms, however, many people are unable to sleep if there is any light in the room, and in such cases the resistance type of radiator should be used, where the heating effect is given without any lighting effect, and thus such persons can retire to rest in perfect comfort. For bedrooms there is no more ideal way of heating than the electric radiator, and each year sees more and more use being made of such; but that does not exhaust the applications of electricity for heating purposes. What nicer than an electrical pot for heating shaving-water with no more trouble than inserting a plug attached to a yard or so of wire into a wall socket; and in "My lady's" dressing-room we must have an electrical heater for "My lady's" curling tongs—a heater which is so absolutely under control that there is no danger of having the tongs too hot or too cold, or of injuring the most delicate tresses. And does that exhaust the home comforts of electricity? By no means; for you can dispense with the hot-water bottle and have an electrical substitute, and when laid down with an attack of influenza you can have—if you wish it—an electrical poultice on your chest. At breakfast you may have your coffee steaming hot from an electrical coffee-pot, and can watch your eggs boiling before you, so doing away with the temptation to use language at the cook, and adding its little quota to the home comforts. And not only so, but it is not the Utopian conception of a day dreamer that electricity could do all the cooking, for it is a quite practical thing, and not so very expensive either. At the Electrical Exhibition so recently held at Olympia the model electrical kitchen attracted much attention, and not only so, but a dinner for 65 persons was cooked entirely by electricity and set down for a total current cost of 4s. 8d. at 1d. per unit. This is scarcely an exorbitant sum. I have also here on the table another adaptation of electricity in the shape of an ozoniser to purify the air and disinfect it by the generation of ozone. This is, perhaps, the latest field which is being commercially exploited by electricity, and the effect of such a manufactory of ozone in one's dwelling can be readily imagined. Foul air is purified, and an atmosphere of healthfulness produced which the finest coast resort or mountain sanatorium cannot give. Indeed, gentlemen, the applications of electricity in the home are now so numerous that were I to expatiate on them all, the time would be too short to enable me to deal more particularly with electric lighting, the branch which, no doubt, interests the most of us here to-night more closely than any other. Now, in dealing with electric lighting, we have all the points raised at the outset of this paper to consider, and so we will deal *seriatim* with them.

The purpose in view, I take it, is to give light, to give light effectively, economically, and, shall I add, unobtrusively. This, you will no doubt grant, is an axiom, and yet I venture to say it is more honoured in the breach than in the observance. When primitive man rubbed two pieces of dry stick together and so got fire, he placed them on the ground, heaped on some more, and, having made a cheerful blaze, sat down and calmly looked into it, content no doubt with his inventive genius. Discovering, however, the want of portability of this method of obtaining light, he took a pine splinter or some dried rush pith and carried it in his hand through the dark glades of the primeval forest. And so when the rush light gave place to the cruisie, and the candle and the gas jet, we, still under the influence of these primæval instincts, placed each of them at a very moderate altitude, so that, in fact, "all who are in the house may see the light," to use a scriptural phrase. And now to-night, after centuries of use and wont, we will have, as you see exemplified in this very room, a sample of that unobtrusiveness to which I refer, because I believe I am safe in saying that 90 per cent. of you on coming in turned your eyes in the direction of these lamps. Certain I am that under normal conditions such would have been the case.

Now, lighting is only effective when one can get sufficient illumination where required and nowhere else; it is most economical when all the available light rays are concentrated in the desired direction, and often it is most unobtrusive when both these conditions are fulfilled. As the quality of unobtrusiveness brings in the vexed question of electric fitting, it may be as well to deal with that part of the subject now. And in dealing with electric fitting we must also consider two others of the condition—namely, the effect of each part of the arrangement on its immediate surroundings, and the general effect or "hang" of the whole scheme. And here, by the kindness of Mr. Harold Watson, of the Helland House Manufacturing Company, you will see a series of designs illustrating various periods in the electrical fitting. Of course, the first stage was the inverted gas fitting, a by no means handsome arrangement, and from this we have progressed until we now reach what might be called modern development. There is a still later step, an ultra-modern art which in one bound has carried us back into a field of barbaric ornamentation, which is neither fish, flesh, fowl, nor good red-herring (neither Egyptian, Greek, Arabic, nor good Anglo-Saxon), and whose only saving grace lies in its oddity and the moral courage of the designer. The craftmanship in the most of these fittings is exceedingly crude; and, personally, I consider that crude craftmanship can never be called art, and that artistic design is only spoiled by such craftmanship. I will run a few slides through the lantern illustrating the trend of modern design. But now let me point out one error which mars each and all of these designs—they are all calculated to draw attention to the source of light, a relic of our primal instinct. And with electric light there is not the slightest excuse for pondering to such a depraved taste, yet designer after designer arranges the lines of his design so as to harmonise with the electric lamp bulb or shade, and to throw it into stronger relief, and then, when the eye craves—perhaps, even demands—some slight consideration, an attempt is made to meet it by shielding the light from view by such makeshift devices as obscured lamps, and glass and silk shades—devices which rob us of from 20 to 70 per cent. of the possible light given out by the lamp. Now it is decidedly bad policy to waste—to deliberately waste—electrical energy, if it is possible to use it effectively, because it simply means that the running cost is so much higher than it ought to be. If you have a room requiring 10 16-c.p. lamps obscured, and with shades on them, giving, say, a total obscuration equal to 50 per cent.—a by no means uncommon event—you could obtain the same total effect, as far as light is concerned, by 10 8-c.p. clear lamps, and this with half the consumption of energy. And hence the importance of considering carefully whether or not we are moving on right lines in our lighting schemes.

Within recent years a decided improvement has been effected by such ideas as that of the Linolite Company, for example, and more recently for shop-lighting by the introduction of silvered reflectors behind the lamps, giving a concentration of all the available light rays in one desired direction. Now, such a method of lighting is at once the most effective and economical, but it is quite apparent that this method of lighting and the orthodox electrolier have nothing whatever in common. And at this stage it may be as well to crystallise my idea of the ideal lighting into one sentence—viz, get the light but conceal the source of it. In other words, have no visible electric lamps or fittings. There are various ways and means of concealing electric lamps and still obtaining the lighting effect, and I may just indicate a few of them. The most straightforward way is, of course, as already mentioned, the use of lamps placed higher up, backed by silvered reflectors, and so spaced that an even distribution of downward illumination is attained.

Digitized by Google

Such a method of lighting is at once the most natural, efficient, and economical, and is just the most delightful for reading or sitting under. But at once you will meet me with the objection that the ceiling is left absolutely in shadow, and what becomes then of the pride of the plaster worker and the decorator, who left their handiwork flashing proudly in its coat of mingled ivory and gold. Well, I frankly plead guilty of rank heterodoxy. I admire a ceiling which is dark under artificial lighting. And I have a reason for that also. Now for a moment consider the charm of "night." Poets have sung it, prose writers have waxed ecstatic over it, novelists and playwrights have used it as the chosen setting for their choicest scenes. And what, pray, is its most charming feature? Is it the moonlight? Well, that is nothing more than sunlight by reflection. But is its charm not rather in a dark canopy—may I not call it ceiling—studded with a myriad points of light? And so I venture to think that a ceiling without any direct lighting, but whose darkness is pierced at many points by gleams of light which brighten the rest of the room would be more restful than our present methods. In fact, in my opinion—I may be an extremist—any method would be better than our present one. Because it is really most unkind of anyone to invite me as a guest and then permit his hall lantern to inflict a sharp blow on my optic nerves as I am ushered into his house, and when shown into his otherwise hospitable "salle de manger" to allow his modern art electrolier to repeat the infliction with a five-fold force. Why, it's a positive act of war! A ceiling nicely panelled off in wood or plaster and with cupped recesses into which the cap and, say, one-third part of the lamp (a spherical one) would fit, leaving two-thirds below the level of the ceiling, would, I think, look just not half bad. I would have these recesses painted with a glossy white enamel, or lined with silvered-glass reflectors, the lamps to be of 2½ c.p. to 5 c.p. each, and placed so as to ensure an even distribution of light.

(To be continued.)

THE COMMERCIAL TESTING OF SMALL MOTORS UP TO 15 B.H.P.*

BY THOMAS CARTER, A.M.I.E.E.

An enterprising ironmonger hung in his window a card inscribed with the legend, "If you do not see what you want in the window, please step inside and ask for it." A customer entered the shop, and to the smiling assistant said, "Kindly give me a Bath bun"; to which the assistant replied, "The baker's, sir, is next door, and there you may be supplied; or, perhaps, you want a bathbrick, which we have in stock—that would be cheaper than a Bath bun." The customer, according to his temperament, would answer either, "Thanks, a bathbrick will do quite as well as a Bath bun for my purpose," or, "No, a bathbrick will not do, and as you state in your notice that I am to come to see you about what I want, kindly get me a Bath bun as quickly as possible, as I will have nothing but that, no matter what the price is." This imaginary incident, however grotesque and fanciful it be, contains some analogy to the present position of the manufacturer of electric motors, who, like the ironmonger, practically hangs out a card at his office door, saying, "We will give you whatever you want, only come and give us your orders"; and, as a result, since there are customers who insist on having their Bath bun, so to speak—that is, who will have something to which they have taken a fancy when something more nearly standard would do quite as well—there is the chaos of outputs and speeds which the Standards Committee has recently been endeavouring to reduce to something like consistent lines, without as yet much success, since each manufacturer seems to prefer to work to suit his particular class of customers. It is, however, evident that on the whole things are settling down in this direction to greater consistency than was previously the case. A much more serious trouble, especially as regards testing, arises from the enormous number of different voltages throughout the country. Those most commonly used for motors are 100, 105, 110, 115, 200, 205, 210, 215, 220, 225, 230, 240, 250, 260, 400, 410, 420, 430, 440, 450, 460, 480, 500, 520, 530, and 550; but even these are not all, for motors have been specified to run at a given speed on a circuit with a voltage of some such ridiculous value as 204·8. If the man who drew up that specification came to design a motor, especially one of 2 b.h.p. or 3 b.h.p., he would have put down 205 volts and mentally reserved at least 5 per cent. either way in the speed, and he would then have thought himself lucky if he got it. Assuming that the "standard" voltages vary round about 105, 210, 240, 420, 480, and 540, and allowing for motors running at half normal speed, two-thirds normal speed, and full speed as standards, no less than 13 different armature windings are required for each size of motor frame, and even then special intermediate windings have sometimes to be employed.

In designing a test shop at Messrs. J. H. Holmes and Co.'s works for motors up to 15 b.h.p. in quantities, this uncertainty of voltage was the first difficulty that met the writer, and it proved to be almost the only one of any magnitude. The system had to be absolutely flexible, and that in a double sense, because the available source of supply in the case referred to might be at any kind of voltage from 110 up to 500, though 110 was to be the normal voltage. An unsophisticated person might think that it would be sufficient to save up motors to test until a few of the same voltage had collected, and then to run these all together from some common source of power. He would not think so long, however, if he were in charge of a test department which received six motors of different voltages in one afternoon, all to be tested and dispatched on the day after to-morrow, with six people wanting to know the reason why if they were not. The first requisite is that there need be no "looking for volts," as it is currently called in the test shop for larger machines, where there are occasionally wonderful combinations of generators for getting the different voltages required for two or three machines at once. In such a case it is not so important to be able to get any voltage at any minute, as the cost of testing is a smaller percentage of the total cost of the machine; but in the case of small motors, where each shilling is valuable comparatively, the cost of testing is a fairly large proportion of the whole, and there is, therefore, less time to lose. This explains the necessity for perfect flexibility, that is, for having an arrangement capable of testing a motor of any voltage from a source which is at the same, or any other, voltage.

Before describing the actual apparatus used, it may be well to speak of the tests generally made on motors of the size dealt with here. The motors are built up from stock parts, of course, including as a rule armatures and field coils, and it is the writer's practice to have the two latter parts inspected by the test department before they leave the winding shop—the field coils simply having their resistance measured on a portable Wheatstone's bridge, while the armatures are tested by measuring the drop in volts from segment to segment all round the commutator with a constant current sent through the winding from the nearest lamp-holder through a portable resistance of variable value. The insulation resistance is, of course, also measured. The taking of these tests by the test department is not a universal practice, as in some places the winding shop does its own testing of these parts after winding them: but it is found that the check on the winders by the department which will next deal with the parts, and will suffer from the delay if the errors are found only on beginning to run the motor, has resulted in much less time being wasted over putting on faulty motors for test than was formerly the case. It is, in fact, a means of transferring the delay from one's own department to another's—in this case the right one, though that does not always happen—and this is really a splendid thing to accomplish, if a somewhat cruel one. On receiving the complete motor from the assembling shop, presumably ready for testing, the first thing to assume is that the brushes are wrongly set or insufficiently bedded in, and, therefore, this is always checked over. It is a curious fact that hardly one man in ten in an ordinary way can be made to realise how much difference the condition of the brushes may make to the first run of a machine, and yet it is one of the most important points to attend to. A little may be said, in passing, about carbon brushes for motors, though there is time for only a very vague reference to this matter. As a rule the writer uses, for all machines, from 1 b.h.p. right up to motors and generators of, say, 150 b.h.p. to 200 b.h.p. or kilowatts respectively, one of three sizes of brushes, 1in. by 7-16in., 1½in. by 7-16in., 1½in. by ¾in. respectively in contact area. There is a 1in. by ¾in. brush for low-voltage machines, and there are two other sizes, 1¼in. by 7-16in. and 1¼in. by ⅝in., necessitated by a peculiar design of brush gear on two sizes of machines only, but practically only the first three sizes have to be stocked in large quantities. It is not pretended that these three sizes will give perfect results in all cases that can possibly crop up, but it is wonderful how far they are found to be quite suitable when there is nothing else in stock. It is, of course, remarkably easy to supply spares when so few sizes are used, and altogether this arrangement compares very favourably with the practice of a firm known to the writer in America—where the standards come from!—which used at least 60 different sizes of brushes for machines ranging from ¼ b.h.p. up to 60 b.h.p. The grade of carbon used is quite ordinary—namely, what is known as "Crown" quality, made by Conradtz, of Nürnburg—and this has been found to give quite as good results as other more expensive grades,

* Paper read before the Newcastle Local Section of the Institution of Electrical Engineers, Dec. 11.

Digitized by Google

and to run very quietly and sweetly. In cases where special brushes, generally of low specific resistance, are required, the writer used to use "graphitic" brushes, made by "le Carbone," of the quality known as Z, which were good, but expensive, as all low-resistance brushes seem to be. Afterwards brushes were used in these cases made of a mixture of carbon and metal dust, which reduced the resistance, but gave poor results if the commutator tended to be hot at all, as in that case, or if there was the least sparking, the metal particles appeared to fuse on to the copper of the commutator, making it very rough in a short time. Recently, however, the Morgan Crucible Company have been making "Morganite" brushes, which are of quite special construction, and are often found to be very good in the difficult cases which crop up from time to time, as they can be built up of copper and graphite, or of graphite of varying specific resistance, or in almost any way desired to suit special cases. To enter further into this matter here is impossible, however: the subject of brushes and commutation, though a most fascinating one, lies outside the scope of this paper.

The motor, then, has had its various parts checked over while the brushes have been the subject of this little digression, and it is ready for its running tests. It is useful at the outset to find the "neutral point" on the commutator corresponding to the armature conductor in the centre of the gap between the pole-pieces. This is most easily done by finding experimentally the position of the brushes where the motor runs at the same speed in both directions of rotation. The brushes will need to remain in this position for a reversible motor, but in other cases a better result can usually be got with the lead a little backwards from this point. It is important to notice that the further the brushes are away from neutral, the less efficient is the motor. The writer recalls one case where there was too weak a field and too strong an armature, in which the light load current of the motor, which is a rough criterion of efficiency, varied from one ampere to 11 amperes when the brushes were moved from the neutral point to a place not abnormally far back from it. This was a special case, but the tendency is always the same.

The motor can now be set to its temperature run, after getting some readings of speed variation with varying loads, as well as seeing that any speed regulation by shunt resistance specified can be carried out, and attending to any other points needing special notice. For the current of the motor of full load during this run it is usually sufficient to assume an efficiency and calculate back from the required brake horse-power: it is, that is to say, unnecessary to take a brake test of every motor, though this should be done as often as possible. When there is no specification as to the length of the temperature run, the writer is in the habit of taking as sufficient;

> One hour for a normal 1-b.h.p. frame:
> Two hours for normal 2-b.h.p. and 3-b.h.p. frame;
> Three hours for normal 4-b.h.p. and 5-b.h.p. frames;
> Four hours for normal 7½-b.h.p and 10-b.h.p. frames;
> Five hours for normal 10-b.h.p. to 15-b.h.p. frames;

especially if they are of standard winding and a considerable number of similar tests have been taken before. It is probable that no motor, however small it be, can reach a limiting temperature in one hour, but, on the other hand, if all the tests are made on the same length of run it is easy to say from experience if the motor is going to be satisfactory or not, and it is naturally very important from the manufacturer's point of view in these days to cut down the time of testing to the shortest which will leave him quite certain that the motor is good.

At the end of the extended run at full load or overload as may be specified (during which readings should be taken, at intervals of not longer than half an hour, of all instruments, speed, and behaviour at the brushes), the temperatures of various parts of the motor are taken as accurately as possible. The writer knows of no measurement which is less satisfactory than that of temperature taken in the ordinary way by a thermometer, with the bulb covered up by a piece of waste, felt, or putty. Even if, as is sometimes done, the bulb of the thermometer is wrapped up in leadfoil, and covered with a felt pad of a standard size, it is almost impossible to repeat a set of temperatures, within 5deg. or even more, on any small motor if another run be taken under exactly the same conditions as the first. The initial temperature of the atmosphere makes a difference, and even if on the two occasions the initial temperatures are alike, the condition of the surrounding atmosphere will cause the final temperatures to be higher or lower according as the air is stagnant or in motion. The difference is usually exaggerated if different observers take the two sets of temperature. The thermometer is the only means available for getting temperatures of the metallic parts, but for windings the method of calculation from increase of resistance is much more satisfactory, always provided that some common-sense is used, and the same temperature is not specified to be obtained by this method as by using a thermometer, as the latter measures superficial rise of temperature only, which is always less, and may be much less, according to ventilation facilities in the motor, than the average rise of temperature as calculated from increase of resistance. Consulting engineers are beginning to specify this means of measurement, but in some cases, unfortunately, they are transferring the old 70deg. rise into the new specification, which is absurd.

The insulation resistance should now be tested, both of the various parts of the motor and of the motor as a whole to its frame, which may be taken as "earth." This is most satisfactorily done by applying between the windings and the frame an alternating pressure of, say, twice the normal voltage of the machine with a minimum of 500 volts. To get this conveniently, a small transformer is used with a variable primary voltage and a variable secondary winding, and the secondary voltage can be estimated with sufficient accuracy by lighting up from it a set of incandescent lamps in series and observing the brightness of the filament. This would probably not be a suitable opportunity of using the delightfully naïve suggestion of a student whose examination paper the writer once had the pleasure of correcting, and who, in answer to the question, "How would you find out if there was a difference of potential between two terminals?" replied, "Put a man across the terminals." The writer considers an ohmmeter test of insulation resistance to be of little value compared with the other, as there may be cases in which a good result is got with the ohmmeter, while the insulation goes down altogether under the alternating voltage test; it is, in fact, taken mainly to satisfy some customers who are only happy if they can see some definite figure put down to indicate the goodness of the insulation, quite regardless of the possibility of error in the instrument used: and this seems to be fairly great in an ordinary ohmmeter which is sensitive to external fields.

In cases where brake tests are made, while the old-fashioned rope brake or one of its modifications is perhaps as accurate as any other, it takes a little time to rig up, and needs a considerable amount of attention to get good results, and the writer has lately tried instead one of W. G. Walker's air dynamometers, which consists essentially of a calibrated fan fixed directly on the motor shaft, the blades being adjustable so as to give varying torque, and consequently a considerable range of power is available. The disadvantage of the arrangement has been found to lie in the fact that for a given arrangement of the blades the horse-power absorbed is proportional to the cube of the speed, and thus, unless the driving voltage is absolutely constant, the variations in speed cause temporary variations of the third power in the result, which largely increases the error due to necessary small inaccuracies in reading. Further, the distance of the blades from the floor, as well as the nature of the base on which the motor is standing—some conditions allowing a greater disturbance to be set up by side draught than others—seem both to have some influence on the absolute accuracy of the result. On the whole, however, such an apparatus as this is most convenient, and this particular dynamometer has been found to give good results, which coincide with very fair accuracy with those got from a rope brake, when sufficient care is taken in the directions shown by experience to be necessary.

So far, this paper has been of a general nature, and might apply to any test shop. It may be of interest now to describe in some detail the arrangement of apparatus designed, as has been mentioned, by the writer for use at the works of Messrs. J. H. Holmes and Co. There is, let it be quite understood, absolutely nothing new in principle in any of the apparatus, but it is hoped that those who are interested in such work may find some suggestions here that may be of use in the future. The writer knows that a paper of this sort would have saved him a good deal of time in getting out his arrangement, but he was unable at the time to discover any source of information.

It would serve no useful purpose now to lay before you in detail all the suggestions of different methods that crossed one's mind in the preliminary consideration of the method to be adopted, as, for example, whether one large motor should be driven from the power-house at 110 volts, and should in turn drive three or four small generators of variable voltage which would supply the motors on test, or whether some other entirely different arrangement should be adopted. These, and many other points, came up for settlement, but the final decision, the wisdom of which one likes to think has been shown in practice, was to deal with each motor entirely through its own set of apparatus, and to have nothing common to all the motors being tested, except necessarily the supply from the power-house, between which and the test shop only one pair of $^{19}/_{14}$ cables is available, carrying 100 amperes at 1,000 to the square inch. These cables are brought to a small distributing board, with four double-pole fuses branching out from one double-pole main switch, each feeding one switchboard and other apparatus complete in itself for testing one motor. Thus, while the shop is arranged at present for testing four motors simultaneously, it will be sufficient to describe the apparatus for one motor, as the whole shop is simply made up of that multiplied by four in every particular.

Set out in a diagram, the apparatus for testing one motor is shown in Fig. 1. Referring to this, 1, 2, and 4 are three

Digitized by Google

standard motor carcases of the size giving 10 b.h.p. at 1,000-1,100 r.p.m. The field of each is wound to go direct on 110 volts, and to have, with no resistance in series, the maximum possible number of ampere-turns for the particular size of field coil employed. The mains from the double-pole fuse already mentioned as being connected to the power-house on the distributing board are brought to a double-pole switch on this testing board, and connected thus through an ammeter, A, to the centre pair of a row of five pairs of terminals, T, any pair of which can be connected up by short wires, with suitable sockets on the ends, to any other pair, top to top and bottom to bottom or *vice versâ*. There are also two sets of four small terminals, T_1, connected up to the large power-house terminal, T, as shown, while a fifth terminal, T_3, is coupled on each side to the large terminal to the left of the power-house pair. The other small terminals, T_2, can be coupled directly by means of a short rod of copper to the T_2 are connected to their respective shunt field windings through an ammeter, A_1, on one pole, and on the other pole a single-pole switch and a resistance, W, consisting of 24 steps of about 20 ohms each. This is the same for all four field circuits. In 2 and 4 there are, in addition, resistances of 24 steps of one ohm each, so that the whole of this resistance, W_1, is a little more than one step of W. These give fine regulation of the shunt current in 2 and 4, as by their means any whole number of ohms from 0 to 480 can be obtained. Further, in the field circuit of 3, the motor on test, there are two additional resistances of about 500 ohms each, connected to three terminals, as shown, vertically above each other, this allowing one or both of the 500-ohm resistances to be put in circuit or cut out by being short-circuited by means of a copper rod sliding through the holes in all three terminals, and capable of being clamped in any position so as to put in circuit or short-circuit the desired resistance. Thus a total of about 1,500 can

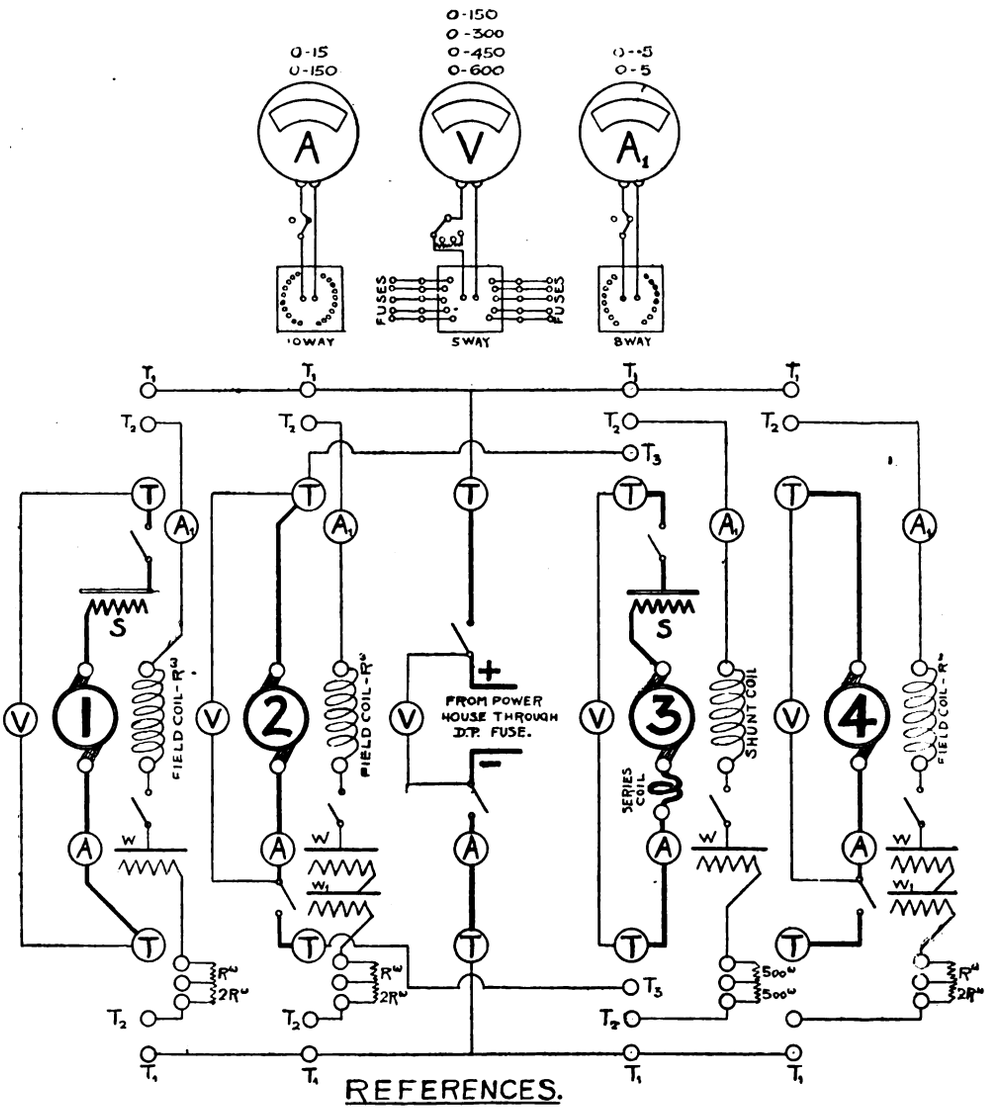


FIG. 1.

terminals, T_1, vertically opposite them, and it will be seen that the T_2 second from the right-hand end can be coupled either to this power-house T_1 row or to the T_3 joined to the large terminal next the power-house pair.

The motor on test is that marked 3. It is shown as compound wound, but may, of course, be shunt or series as well. It will be seen that between each pair of large terminals, T, with the exception of the power-house pair, there is connected the armature of one of the machines 1, 2, 3, and 4 through a single-pole switch, a starting resistance, S, of about 50 ohms, suitably graded in about 12 steps, and an ammeter, A, in the case of 1 and 3, while in circuit with 2 and 4 there is no starting switch and resistance, but only a single-pole switch, on the opposite pole from that in series with 1 and 3, and an ammeter, A. There is also a voltmeter, V, on each pair of terminals, coupled up in each case to be most suitable for the conditions—as motor or generator, that is to say—under which each machine will run, as will be evident from what follows. Further, the terminals be got in the shunt circuit of the motor on test, rising in steps of about 20 ohms, which is found in practice to be sufficiently small. There is a similar arrangement in the case of 1, 2, and 4, but the values of the resistance are R and 2 R ohms respectively, R ohms being the resistances of the 110-volt coils of 1, 2, and 4. These coils are always excited through T_2 coupled to T_1—that is, from the power-house voltage, whatever it may happen to be. It may happen that the testing part of the power-house plant is running at some voltage other than 110, for tests in other parts of the works, and in that case this motor test might have to be run from this voltage also. Hence it may be necessary to excite coils 1, 2 and 4 from a voltage of from 200 to 250 or of from 400 to 500. In the former case, by sliding the short-circuiting rod out from the top terminal connected to R, but leaving the other two still short-circuited, R is put in series with the field coils, also of R ohms resistance, and hence there are still only about the proper volts on the coil, the rest being absorbed in R.

Digitized by Google

Similarly, if the power-house is working at the highest volts, it is only necessary to remove the short-circuiting rod altogether to get 3 R ohms in series with the R ohms of the coil, which will thus take only one-quarter of the total voltage, or again, about the right amount. It may also be necessary occasionally to use higher volts in the power-house if there happened to be on test four motors at once all of 15 b.h.p., as then the $^{19}/_{14}$ mains would not carry the requisite power at 110 volts. In that case, also, the resistances R and 2 R would come into use. All the apparatus shown in the diagram, and described above, including the carcases and coils of 1, 2, and 4, is a permanent part of the works testing plant. The movable parts are only the motor on test, 3, and the armatures for 1, 2, and 4, which are in every case standard, and taken from stock as required. The method of using all this apparatus is the next thing to be considered.

In cases where 3 is to work at the voltage available in the power-house, 1 and 2 are not used. The shunt of 3 is then excited from T_1, and its armature circuit is coupled directly across to the power-house terminals; this completes the necessary connections. Load is put on 3 by bolting it to 4, and having in 4 an armature which will generate the same voltage as 3 is working from. The terminals of 4 can then be coupled up directly to the power-house terminals, and when the voltage of 4 is adjusted by means of its shunt resistance, it can be switched in to run in parallel with the power-house generators. To vary the load in 3 is then simply a matter of adjusting the shunt current of 4, which is, of course, supplied from T_1. It is here that the use of the one-ohm steps in W_1 is found for getting small variations in the load of 3.

(*To be continued.*)

SOME POINTS RELATING TO STORAGE BATTERIES AND BOOSTERS.*

BY L. BROEKMAN, M.I.E.S.

Omitting from this paper detailed reference to the gradual developments which have taken place during the past in the art of producing reliable storage batteries, I address myself at once to such matters in connection with present-day cells, their function and management, as, I am pleased to believe, will prove of some practical interest. While naturally holding my own opinion as to the relative merits of different types and makes of accumulators, I shall endeavour to keep this in the background, and to steer clear of comparisons as much as possible. What are the features, mechanical and electrical, which come under review for stationary work, lighting, power, or both, when judging the rival qualifications of cells from various makers: (1) weight of electrodes; (2) efficiency and permanence of contact between conducting frame and active mass; (3) how expansions and contraction of active material are provided for; (4) means adopted to equalise activity of plates in every part: (*a*) porosity and (*b*) open structure—*i.e.*, "linked surfaces" *versus* "separated surfaces," owing to central web; (5) conductivity of framework, constant or diminishing; (6) relative capacity and mean pressures at various rates of discharge; (7) emergency discharge permissible; (8) normal and maximum charging rates, mean and maximum pressures; (9) volume of electrolyte and maximum density; (10) method of mounting sections; (11) supervision required; (12) price.

Given the battery which comes out best on points allotted under the above headings, its life, while retaining a high percentage of rated capacity, will depend largely on an adequate relation between duties demanded and normal output of cells, as well as on the intelligent observance of working directions. When, for example, a discharge to the full extent is taken from the cells daily in from three to six hours the active material will be in a soft state, and less adhesive. Sediment, therefore, is thrown down more freely, and replating becomes necessary sooner than when, under a less exacting *régime*, the new formation is allowed to assume a crystalline texture. The battery, in effect, is too small for its work. Far the better plan, both from technical and pecuniary points of view, is to provide for a margin in capacity on the safe side, a share of which is almost invariably claimed by afterthoughts and extensions without corresponding facility for increasing the battery output. On the other hand, accumulators worked regularly under normal conditions will be in a healthier condition, and give longer full service, than others subjected to protracted periods of idleness. From the fact that most battery makers are prepared to enter into contracts for upkeep at rates varying between 5 per cent. and 10 per cent. per annum, according to size, service, and locality, it can be accepted that the average life of a set of plates is not less than six years if the value of renewal sections throughout be taken roughly at one half the original cost of the storage plant, and running expenses for periodical inspections be borne in mind. These inspections are to the best interests of both user and manufacturer, and of much greater importance than is usually realised. Interruptions, whether arising from wrong management or from normal wear, are forestalled, and any needful repairs can, as a rule, be so timed as to cause a minimum of discomfort. To the manufacturer, whose reputation is at stake with every battery supplied, they afford opportunities to nip trouble in the bud. Even when no regular maintenance agreement has been entered into, such periodical inspections can, and should, be arranged for. "Fair use" and "proper attendance" remain mere figures of speech without some occasional check. The keeping of simple, but truthful, daily and weekly records is a great help, and strongly to be recommended, but to my mind there is nothing like the visit from the inspector—the more uncertain as to date the better—to keep things in good order.

The neglect, amounting to recklessness, under which some batteries are expected to thrive is astonishing. While at the makers' works scrupulous care is taken to use the purest materials only, and precautions are exercised at every step and turn during manufacture to guard against possible contamination, free and easy methods are the rule rather than the exception once the cells have passed out of their hands. For the sake of saving on carriage, users often obtain acid of doubtful quality from the nearest supplier, preliminary analysis being dispensed with, while water of any kind is considered suitable for making good evaporation. No battery maker would countenance such risks. Even the best soft well water undergoes changes periodically, and cannot be strictly relied upon; with rain-water everything depends on the district—where houses are in the vicinity of chemical works, or of the sea, the rain-water collected is decidedly unfit for use in a battery. Only pure distilled water (not condensed steam from boilers, hot-water pipes, etc.) is really safe for the purpose, and to grudge this relatively small expense is the worst possible economy in the long run. All acid should invariably be ordered from the battery firm. To discuss here the complex chemical changes and reactions which take place in a secondary cell during charge and discharge would occupy too much time. Magnificent text-books on the subject are available now, demonstrating that nearly all the difficulties of past years have yielded to research assisted by modern methods of electro-chemistry, and giving satisfactory explanations of many subtle and hitherto obscure phenomena. Limiting my remarks to the consideration of effects, produced or absent, according to the treatment of a battery by the user, one important point is to prevent the formation of white sulphate, $PbSO_5$, as distinct from the ordinary sulphate of lead, $PbSO_4$, which latter is the normal compound into which peroxide on the positives and finely divided lead on the negatives are converted during the discharge of a cell within the potential difference limits indicated by the makers. Below this safe point the action of the acid on the electrodes becomes greatly intensified, and continuing discharge habitually beyond it, or allowing plates in a discharged state to remain standing for any length of time in an attentuated solution, are the surest ways to produce white sulphate. When this forms between the metallic conductor and the active material, it practically insulates one from the other and lowers capacity. Being extremely difficult to reduce, and more bulky than the active material, it follows that enormous strains will be thrown on to the frames of the plates if there is insufficient free space to allow for the expansion of the active mass. If sulphating be taken in time, prolonged overcharging at half normal rate will improve matters, but on no account should such overcharges become an institution. Against doctoring the electrolyte by the addition of sulphate of potassium, sodium, or of caustic soda, users cannot be warned too strongly—this only leads to different and ineradicable trouble. Should any interruption occur in the course of the initial charge of a battery from a dry condition of the plates, notably during the first 20 hours—*i.e.*, before the specific gravity of the electrolyte has begun to rise again—the plates are particularly prone to become badly sulphated, and much trouble may result. Make sure, therefore, that the generating plant is in thorough working order before filling the cells with acid, and commencing a first charge. Prof. Ayrton, in one of his tests, has found that when the peroxide on the positives had fallen to 31 per cent. the cell very rapidly loses its E.M.F., which he attributed partly to the layer of sulphate excluding the mass beneath from further participation in the discharge, and partly to the appearance of peroxide on the negatives. Herr Liebenow, on the other hand, has conclusively proved by very simple means that the rapid drop of pressure which determines the exhaustion *pro. tem.* of a cell on discharge is almost entirely due to want of free acid. By continually urging acid through the pores of the negatives on to the positives, thereby reinforcing diffusion while maintaining level and density, he obtained nearly three times the normal capacity from the plates. During a rapid discharge, for instance, the SO_4 contained in the active material is used up at a much quicker rate than it can be replaced from the surrounding electrolyte. Hence the fall in pressure is sharp under continuous load; also, the recuperative effect is very marked when the current is interrupted, and the deficiency is made good by diffusion.

Coming, now, to the abnormal rise in potential difference towards the end of a full charge, and the fugitive high voltage given by cells immediately on breaking the charging circuit, commonly called "gas effect," this has been found to be due to the presence of unstable products, such as ozone and persulphuric acid, which only make their appearance to be decomposed at once. This high voltage, unfortunately, is quite short-lived, and available only when a discharge is taken immediately on switching off the charging current. An instance when that effect can be taken advantage of to the best purpose occurs when a battery is operated through a reversible booster, say on a tramway system, which, as a rule, provides frequent and marked positive and negative fluctuations. Under such conditions the watt-hour efficiency of batteries has been proved as high as 80 per cent. While on the subject of charging, I will briefly refer to the two principal methods employed: (1) with constant current; (2) with constant voltage. The former is almost invariable practice in the United Kingdom, while the latter is generally adopted in France. In point of time, for a *complete* charge, there is little to choose between the two. Applying a constant current at normal rate takes about eight hours to fill a battery. If charged with constant voltage, as much as 50 per cent. of the total charge is effected during the first hour, 75 per cent. after two hours, and 83 per cent. after three hours, but then the current is cut down very low, and it takes a long time to complete the remaining 17 per cent. With the constant-current method the best

* Paper read before the Dublin Local Section of the Institution of Electrical Engineers, Dec. 14.

charging rate to adopt is at or near the normal indicated by the makers. The effect on the electrolyte, without being violent, is sufficient to promote a healthy action and uniform density, enabling reliable hydrometer and voltmeter readings to be taken, useless and harmful overcharging to be avoided. Overcharging frequently goes hand in hand with a low charging rate. Ten per cent. excess in ampere-hours over previous discharge, both operations metered for choice, is quite enough under ordinary circumstances, the charge being pushed on to a milky state of the acid, say, once every week or fortnight, and then continued for a length of time according to the depth of cells in use. Habitual overcharging is wasteful and decidedly detrimental, tending to cause excessive formation, to unduly increase sediment and thus to shorten the useful service of the plates, besides giving rise to violent spraying with its attendant evils if a high rate be maintained. When overcharging at a low rate is practised, the case is perhaps worse, because no outward manifestation takes place; formation of spongy lead on the negative plates then becomes the immediate trouble, bringing complication in its train.

In some castles and country houses, inhabited at long intervals only and then merely for brief spells, batteries are worn out practically by charging alone. An occasional artificial discharge, working the cells through the entire cycle and forming a fresh surface, would do them all the good in the world. Prior to any prolonged period of disuse it is essential to give an abundant charge to the battery, so as, *i.a.*, to provide the conducting framework of the positives with an unbroken film of peroxide, thereby reducing local action to a minimum. This film ceases to be protective if even a short discharge be taken from the cells subsequently—it is, therefore, best under the circumstances to disconnect the leads at the battery terminals immediately the charge has been completed. To remove the acid from the cells, after due preparation of the plates, is unquestionably the safest plan of all to adopt in such cases, but this needs care and entails some trouble; moreover, the battery cannot then be made available on a surprise visit. On discharge the capacity depends on the rate at which current is taken from the cells, so, for instance, in a well-constructed accumulator the yield of ampere-hours obtainable at the one-hour rate is approximately doubled if the discharge be spread over nine hours. Some of the following rough battery data may be found useful on occasions: Cells in glass boxes—weight in pounds, about one-half of ampere-hours at maximum capacity; space occupied—cells erected all on one level with narrow gangways, equals about 3 square feet per kilowatt-hour at maximum capacity; price, £4 per kilowatt-hour at maximum capacity. When glass boxes are used, "bolted" connections between cells have the preference to "lead-burned" joints, as the heat of the soldering jet, unless very carefully applied, is liable to crack the glasses; besides nursing, repairs and cleaning are rendered much easier with the former. Bolts and nuts must, however, be encased in non-corrodible metal, so as to afford thorough protection against acid spray. In determining the capacity of a battery for a given installation output of dynamo, parallel running, frequency of recharging, and probable extensions are factors to bear in mind besides the actually expected current consumption. A rule adopted by some firms, and said to work well, is that a battery for a private residence, capable of lighting continuously during three hours the total number of lamps installed, will deal comfortably with the average Saturday to Monday load, and last through a third night in winter at a pinch. This may be so, but it can only serve as a very general guide. An adequate reserve on emergency, when all lamps in the house may be turned on simultaneously, should never be encroached upon, which implies that 1·9 volts per cell must be regarded as the potential difference limit on low discharge for regular use.

The site of the accumulator house as regards accessibility, length of mains, and well-being of the battery is the next important consideration. Immediate proximity to stables or manure heaps has been shown to be detrimental to the life of cells on account of ammonia troubles. Mr. Vicarey read a most interesting paper on this subject recently before the Faraday Society, and I feel convinced that there is a great deal in his contentions. Vitrified brick laid on concrete and grouted with pitch makes a good battery-room floor, which should have a suitable slope for drainage. A natural draught from openings near the floor at one end and exits near the top at the other will usually provide adequate ventilation to free the room from acid spray, and to keep down temperature; for large batteries, heavily worked, it may be necessary to supplement this by a fan. Protect the battery from direct sun rays, but give the attendant the benefit of good day and plenty of artificial light, especially portable hand lamps. Water supply should be laid on and a sink fixed in the battery-room; space for a small desk for writing up and preserving records it is advisable to provide in the engine-house. Except in very much exposed localities, it is scarcely necessary to heat the battery-room during our mild winters; low temperature merely limits the capacity for the time being, but does no harm whatever to the cells. Let the cells be arranged all on one level if possible, with gangways at least wide enough to admit passing a carboy basket along. With glass boxes double tiers are admissible, but experience is altogether against placing cells beyond easy inspection and handling; also ample head room should be allowed above the cells. For battery pressure exceeding 250 volts the modern practice of double insulation—stands from earth and cells from stands—has effected a great reduction in the number of weak cells. Coming to accessories, trays filled with sawdust or sand are better for glass boxes than lead discs, as the latter do not evenly support the weight of the element. Hydrometers should read in single degrees on an open scale. It is best not to allow them to remain in the cells, where they are liable to become sticky and grimy after a short while, rendering them unfit for taking accurate readings. Cell-testing voltmeters of the cheap variety commonly met with are more or less a snare; almost any reading can be obtained with them according to the position in which they are held, their accuracy, moreover, being influenced by the number of times the instruments have been dropped. A neat and safe way of using a better class portable voltmeter with central zero, the needle swinging in a horizontal plane, is to attach the instrument to a short board, the lower side of which is provided with lead contact studs. By placing this board across the equalising bars of a cell, a slight pressure downwards will secure a reliable reading, which can be marked down at once on the note pad at the side. The time-honoured arrangement of hand regulating cell switches, with its shortcomings, still does duty in nearly all private house installations, and automatic switchgear for the purpose, both by reason of greater cost and complication, has been applied in isolated instances only.

When current to the lamps is invariably supplied from the battery alone, overcharging of end cells can be easily avoided. Not so when the dynamo is running part of the lights while charging the battery at the same time. Without adequate supervision some end cells then are liable to receive considerably more than their share of charge, while, if the outside load be heavy, the body of the battery may be kept short of current, possibly have to discharge occasionally. This destroys uniformity if it has not worse effects. Larger capacity cells for regulators are occasionally used to keep down the charging rate per positive plate, or paralleling several end cells on charge by means of a suitable switch to reduce their number, and the charging rate for the regulators is equally effective. Counter E.M.F. cells in one of the supply leads is another remedy, and a good one, yet rarely adopted. For any fair-sized installation, say of 500 lights and upwards, the additional cost of a semi-automatic reversible booster in place of a charging booster is not great, bearing in mind that the number of cells ordinarily required can then be reduced by approximately 14 per cent. Or, to put it in another way, 8 per cent. of the line voltage is about equal to the number of cells which can be dispensed with when the battery is discharged through a booster. As neither cell switches nor regulating leads are required then, further savings are made, which go towards cancelling the extra cost of the semi-automatic machine. The ease and delicacy of voltage regulation obtained with a booster is far ahead of the best that can be done by means of cell switches. If the pressure from a gas or oil engine-driven dynamo varies considerably so that the pulsations are reproduced in the lights, floating a battery across the line has the desired steadying effect. To that end set the cell switch for the correct line pressure, running the dynamo to give about 2 per cent. higher voltage as a mean. Of course, the cells must not be switched in parallel until the generating plant has settled down to its work at that pressure; this is a convenient way of husbanding the capacity of a battery for long runs. To obviate the necessity for a large number of leads with cell switches for high-voltage batteries, some ingenious devices have been described. One means is to connect every fourth cell at the right-hand end of the battery to a main cell switch, and to use the first three cells at the left-hand end for connection consecutively to an auxiliary regulating switch, the two switches interlocked. The saving in leads is obvious. One difficulty, however, is to guard against charging certain cells in the reverse direction if the number of cells in the charge circuit happen to be less than that discharging at the time.

The practice of starting internal-combustion engines by running the dynamo as a motor off the battery should be discouraged. Without special gear this puts an exceedingly heavy strain on the cells at a time when they are least able to bear it—viz., as a rule, when they are low down in the morning after a night's run. Two smaller batteries in parallel *versus* one large single set—the drawbacks to parallel working far outweigh the almost solitary advantage of having one battery available for use while the other is being cleaned or under repairs. Two full-sized batteries by all means, operated turn and turn about; this promotes a good crystalline formation, and results in higher capacity and longer life, but no parallel working if it can be avoided. In modern cells, moreover, so much free space is provided for sediment that the necessity for its removal does not arise until the plates are worn out. The removal of sediment from older-form cells is best entrusted to the makers, as they keep a staff experienced in that work, and because much damage may be done by neglecting the necessary precautions. Great care is required during the removal of the plates from the electrolyte, as the negatives oxidise quickly, heat up and shrink when exposed to the atmosphere; it is important, therefore, to prevent their becoming dry. Failure to obviate this will not only entail a subsequent full deoxidising charge of about 40 hours before the cell will give capacity again, but in shrinking the active material is liable to lose contact with the conducting framework, and to seriously impair the capacity of the negatives. For the removal of a few defective plates only in several groups utilise the good plates of one or more of these, putting entirely new groups into the latter cells. Old and new plates mixed in the same group do not divide the work equally between themselves, and then discharge into one another after the circuit has been disconnected. Such groups invariably go to pieces in a comparatively short time. Sometimes one single cell alone gives trouble in a battery, and on renewal of the plate section the question arises how to give the long initial charge without greatly overcharging the entire set of cells in the absence of a milking booster. This difficulty is minimised by asking the makers to forward the new section fully formed and charged, the negative group being packed in wet sawdust. When put into circuit during charge subsequently this will only take from 10 to 12 hours altogether to come up with the other cells; until it does so it must, of course, be cut out during discharge.

Celluloid or kindred substances are undesirable materials to employ in connection with storage cells, whether in the form of containing boxes, separators, or envelopes. Their behaviour is uncertain; notably in proximity to the positive element the tendency of celluloid is towards decomposition, and the eventual formation of sulphate. At one time xylonite was much used for fork separators, being cheaper than ebonite, but, besides obstructing the view between the plates, forks are liable to twist, and to defeat their object; hence they have been almost entirely superseded by glass tube or glass rod separators in stationary batteries. The introduction by the Chloride Company of

Digitized by Google

board diaphragm separators, acting as a complete screen between plates of opposite polarity, marks, I consider, a most important step in the right direction. By rendering it impossible for any treeing to occur, scale or foreign substances to become lodged in the open spaces between plates, the liability of individual cells falling below par is practically excluded. No farther need to peer into cells prospecting for possible shorts; the certainty that, by reason of the efficient protection of electrodes, excrescences, if any, cannot develop and do mischief renders supervision very easy. To keep the cells clean, acid level and density right is really all the attendant has to do in the battery-room. An additional advantage of diaphragm separators is that by holding up the voltage, they raise the useful capacity of cells. This effect is readily verified by exchanging forks or glass tubes for board separators in any cell of low capacity the plates of which are, however, mechanically in good condition; after only a few weeks' regular use this cell will have redeemed its character completely—very likely will have become the strongest one in the whole set. Electrolyte liberal in volume and of 1 215 maximum density only is used, and as no attendant troubles from carbonisation of the wood or any other causes have been experienced in the course of close on five years' continuous employment under all conditions of work board separators have fairly passed the period of probation.

The field for the use of accumulators is constantly and rapidly widening, but by far the most important developments to record in the application of electrical storage are those in its relation to power purposes. Splendid work is being done in that department, and taking into consideration the large scope for batteries operating on variable loads with every prospect of thoroughly sound results, both from technical and balance-sheet points of view, the outlook is the very best. I have heard it stated over and over again that accumulators for power work have proved anything but successful in the past. Why? Because pressure regulation was exceedingly troublesome for one thing, but principally because in almost every single instance batteries were over-discharged day after day, and were then left standing in a run-down condition. Mr. Wordingham on one occasion summed up the situation neatly thus: "Batteries are so useful during light load, and again during heavy load, that the difficulty is to find time for charging them." That's it. Moreover, it must be plain that a heavy load will be far more trying to the cells when near the limit of their useful capacity than when they are fully charged. Not only were these obstacles to successful application cleared away for good with the introduction of the reversible booster, but much smaller batteries now are perfectly equal to the same service in which large batteries were ruined formerly. As a matter of fact, for rapid and frequent fluctuations, fairly continuous throughout any given period—now 200 per cent. above mean value, now down to zero—capacity is not essential, but robust plates able to withstand without detriment rapid charges at excessive rates, and to furnish the momentary peak discharges, whatever these may happen to amount to. Capacity, of course, is needed to do justice to rectangular peaks, to supply current for overtime work or week-end repairs (the generating plant shut down to save boiler and engine hours), and last, but not least, to constitute an unfailing stand-by in case of breakdown of the power supply when the battery takes up the whole load instantly, and keeps matters going until the defect has been remedied. With penalties for default on some tramways of £7 per minute, the value of this capacity, usually one hour at full load, can be readily figured out; in large manufacturing concerns the loss in wages and work through an hour's stoppage may be even more serious. In case of fire at night the battery will light the premises, supply current for running cars out of sheds, and be the means of saving valuable property generally. Then take the advantages from a battery-booster equipment to a combined incandescent lighting and power circuit through constant pressure—*i.e.*, steady light from lamps and uniform speed of motors, favouring best quality of work and highest output from tools or machines. One initial difficulty is met with in arriving at a true appreciation as to the character of load in a given industrial concern. The inefficiency of mechanical transmission by line shafting, gearing, and belts puts a fictitious value on the mean load factor, raising this frequently by 30 per cent. or more. Apparently, therefore, the load is fairly steady, and the engine diagram will prove economical working. But substitute electric motors, direct-coupled to heavy machinery, and driving short lengths of countershafting, preferably provided with ball or roller bearings, to which lighter tools are belted in groups, and the maximum demand will probably be 60 to 70 per cent. of the engine output, with a mean load factor in the neighbourhood of 40 per cent. Hence, with judicious application of battery and booster to take care of all fluctuations, a considerably smaller number of engine units need be run, or, conversely, extensions on a large scale can be effected in the works without entailing additions to the existing generating plant, or drawing on the reserve equipment. The economies in power production costs, wear and tear, etc., are manifest.

As regard first cost of installation, that of a battery, booster, and controlling apparatus is less than one half of the capital outlay caused by the provision of boilers, engines, etc., for equal service, while a covering rate to allow for upkeep is 6 to 8 per cent. The various types of boosters used with batteries, both for charge and discharge, may be classed as follows: constant-current booster—non-reversible; differential boosters—reversible, balanced currents; Highfield boosters—reversible, balanced voltages; solenoid controlled boosters—reversible, shunt field rheostat; carbon pillar booster—reversible, Wheatstone bridge principle.

Constant-Current Boosters.—These are specially suited to mills, factories, residences, etc., where the motor load is of moderate value, one generator having to deal both with incandescent lighting and power. In the ordinary way the switching on and off of motors will cause irritating pulsations in the lights, which the constant-current booster and battery prevent, the regulation being so close that the lighting voltage can be maintained within 2 per cent. The general arrangement is to connect all motors across one set of 'bus bars and all lights across another, the negative 'bus bar being continuous, and common to both sets of positive bars. The generator is then connected across the lighting 'bus bars, the battery across the motor ditto, positive lighting and positive motor bars being joined through the booster. This latter is provided with shunt and series coils so proportioned as to keep the load on the generator constant—viz., a definite value for lighting, and the mean only of the motor load. Any excess demand for power above the average is supplied from the battery, while during periods of low motor load the cells are charged automatically. Moreover, by installing end cells and switches for hand regulation, and making provision for cutting out the booster and directly connecting positive motor bars to lighting bars, the battery is placed across the entire system for use either alone or in parallel with the generator.

Differential Boosters.—Probably the first reversible machine ever put to work was that known as "up and down dynamo," invented by Mr. W. A. Chamen, and which represents the fundamental principle of all differential types. The booster armature was placed in series with the battery, the field being excited by means of a shunt and a series coil. The shunt coil was excited off the line and gave excitation in the charge direction, regulation being effected by a rheostat. The series coil carried the whole line current, or a shunted portion thereof, and was sufficiently powerful to overcome the shunt coil, and to furnish the requisite boost on discharge in addition. As during succeeding years an increasing demand for traction boosters arose, modifications of, and improvements on, the above principle were devised by several inventors. The shunt coil was excited off the battery, making the machine more automatic, but the excitation has still to be varied according to the state of charge of the battery. An armature reaction coil came into use, and an exciter was added to carry the differential coils, and its polarity was reversed according to the line load. Running at a pressure up to 100 volts, and being connected straight across the booster shunt coil (the booster a simple shunt machine) better efficiency resulted, but also increased magnetic lag due to the necessary double reversal.

Highfield Boosters.—The best known type in the United Kingdom is the Highfield automatic reversible booster, invented by Mr. J. S. Highfield. The principle of this machine is based on the battery volts rising during charge and falling during discharge. If, therefore, a constant pressure be arranged to oppose the varying voltage, and the field winding of the booster be placed in this circuit, it follows that the flow of current in one direction or the other, and the consequent reversal of the booster's polarity, is made directly dependent on the battery characteristic. In this way both the degree and the direction of the booster's activity are controlled by the difference between two voltages, one fixed, the other varying—which method at once appeals by reason of its simplicity and obvious efficiency. Motor, booster, and exciter are rigidly coupled together, the booster armature connected in series with the battery. The small shunt-wound exciter is regulated by a rheostat, and its design provides that its pressure is not materially affected by variation in load or slight changes in speed. Connected through the booster shunt coil across the poles of the battery, and in opposition to them, the exciter is now set to give the line pressure. The booster then acts as described, a series coil excited off the line, and therefore in sympathy, giving corresponding boost on discharge, and compensating for speed changes of motor and differences in exciter pressure when varying from no load to full load. This series field is adjusted by a diverter switch. A second series coil in series with the armature accounts in either direction for armature reaction. Another Highfield machine, the semi-automatic, is specially well adapted to lighting systems, in connection with refuse destructors, and for such uses generally where the fluctuations are not sudden or violent, and the battery may be either charging or discharging continuously, or, perhaps, float for a considerable time. These machines, automatic within given limits, depend in their action on the direction in which the current is passed through the booster shunt coil. By means of a rheostat the current in this coil can be varied to any desired extent, and the direction of it be reversed without breaking the field circuit. Series excitation, controlled by a diverter switch, is provided as in the automatic sets.

Solenoid Controlled Boosters.—In the solenoid-controlled booster the machine is shunt wound for its maximum boost, excited off the line, a reversing and regulating shunt field rheostat dominating the field winding. The rheostat itself is controlled automatically by a solenoid, round which passes the whole line current.

Carbon Pillar Machine.—The operation of the carbon pillar machine now introduced into this country depends upon the reversal of the booster field by the variation of resistance in a circuit connected upon the Wheatstone bridge principle. By the difference in mechanical pressure effected on two sets of columns, each consisting of carbon discs, the resistance of the circuit and thereby the direction of the current are changed. The fields of exciter and booster correspond to the galvanometer circuit of the Wheatstone bridge. A bar for varying the pressure upon the carbon columns is pivoted at the centre, one end being pulled down by a solenoid in the main circuit, counterbalanced by the tension of a spring at the other end. To accelerate the speed of reversal, the exciting value can be made three times as great as is required. These machines are particularly suited to deal with very violent and rapid load variations, and by their use the generator output can be maintained constant to within 2½ per cent., provided the battery is proportioned to supply the peaks, and to absorb the average load as charge when the line demand is zero. This careful proportioning of the load between generator and battery is the crux of successful working. In the case of a railway load, for instance, it will be preferable to allow of a variation in the generator output 25 per cent. above and 25 per cent. below normal. By means of a regulator in the booster shunt coil the set may be given a discriminating value—*i.e.*, charging up to a certain amount only—and restricting discharge until the generator output has reached a predetermined maximum. As regards working methods, the directions given with Highfield machines are merely to the effect that the set is to be handled in

Digitized by Google

the same way as a generator. To parallel an automatic set, the exciter is brought to the same pressure as the line when the booster is switched in. To increase load on generator, raise dynamo pressure and decrease exciter voltage. Reverse this process to obtain the opposite effect. The diverter is adjusted when the machine is installed, and will need no further regulation unless the mean load is very largely increased, or when further generating plant is added.

In many combined lighting and traction stations it will be an advantage to have the battery and booster available on the lighting 'bus bars. To that end, a double-pole throw-over switch provided transfers battery and booster on the lighting system as a two-wire unit. For cases of emergency—as, for instance, if the balancer breaks down—an additional single-pole switch is installed to connect neutral battery to neutral 'bus bar after the booster has been switched out. The factor of safety this arrangement gives amply justifies the small extra outlay for switchgear. That self-contained accumulator cars for tramway traction have not given better working results in the past is by no means due entirely, as alleged, to the excessive cost of upkeep, and to the weight of batteries constructed 10 and 15 years ago. There were numerous contributory causes. Given a good track, efficient motors, and gearing, and present-day traction cells having an output of nine watt-hours per pound at the five hours rate of discharge, and quite a different showing will be made. Line batteries at a distance from the power station are applied most successfully for maintaining the voltage at its average, and for reducing the amount of copper necessary for transmission. The following comparison of actual working results will demonstrate this. Transmission distance about 7½ miles, 550 volts, at power-house. 400 volts minimum on line. Copper required without battery—350 amperes maximum transmitted; track drop 78 volts, line drop 72 volts; copper, 300,000lb. Copper as actually installed with battery—167 ampere maximum transmitted; track drop 37 volts, line drop 113 volts; copper, 130 000lb. Thus effecting a saving of over £4,000 in first cost and of £200 in annual charges all told except copper depreciation. Not only are fewer generating units required, but, through the relief from fluctuations, wear and tear thereof are materially reduced, and a reserve provided in case of breakdown.

The use of storage batteries on electric locomotives where an exposed conductor is inadmissible in mills, mines, and for shunting purposes on railways is considerably on the increase. Particulars were forthcoming recently of two accumulator locomotives supplied for service on the Great Northern and Piccadilly Electric Railway in London: Total weight, 65 tons, of which 31 tons battery; equipment, two motors, each 20 h.p. normal, 85 h.p. maximum; 80 cells, 180 amperes normal, 800 amperes maximum; speed, seven to nine miles per hour while hauling a load of 60 tons on the level. Figuring the power provided on the basis of 100 watt-hours per ton-mile, this will admit of two miles continuous haulage of full load with one complete charge of the battery. As usual in the "straight" storage system, facilities are provided for recharging the cells during intervals when the locomotive is standing by means of conveniently located charging plugs. In the mixed system—*i.e.*, battery operating only when trolley or third rail are precluded—the cells are generally recharged by direct transmission, and a relative small battery as a rule does duty.

The task imposed on accumulator makers to produce a battery capable of successfully withstanding the exigencies of use on electromobile was not an easy one, seeing that light weight and small space to be taken up, apart from such amenities as vibration, wash of the electrolyte, and frequent (occasionally rough) handling were the conditions under which a large and lasting output had to be given over a reasonably long period. The performance of 4,500 car miles completed, full capacity, no repairs to plates, and still running, weight efficiency nine watt-hours per pound of complete cell, shows, however, that makers were equal to the situation. Again, much of the credit as regards uniform behaviour and reliability of cells for this service, as well as for ignition purposes, is due, I contend, to protected electrodes; internal shorts in completely enclosed cells, tightly packed and connected together, are especially trying. The usual number of cells employed for vehicle work is from 40 to 44, so as to be divisible into four groups and to admit being charged from a 110-volt circuit. The motor then is wound for 80 volts. Sixty watt-hours per 1,000lb. total weight per mile is a fair average rate to use in computing the power to propel a given vehicle. This rate is called "wattage." A battery having a weight efficiency of nine watt hours per pound would be able to propel itself 150 miles with a wattage of 60. Should the same battery be only 25 per cent. of the total weight propelled, then it follows that it will run a 60-wattage car one quarter of 150 miles = 37½ miles. Conversely, if the mileage be specified on one full charge, say 50 miles, then the proportion of battery weight to total weight is found. In this case 50 : 150 = ⅓.

For recharging batteries from alternating-current circuits, electrolytic rectifiers, called "Nodon valves," have proved very satisfactory, according to Mr. Horace Boot's experience; also the cost of installation was £68 compared with £155 for a motor-generator of corresponding output. Zinc and aluminium alloy plates, in lead cells, with a saturated solution of phosphate of ammonium make up the combination. Mercury arc rectifiers supplied for the same purpose possess important features to recommend them, such as small space occupied, low cost, and the extreme ease of manipulation. Also the efficiency is remarkably high down to one quarter load. Operating from a 220-volt 60 cycle alternating-current circuit the efficiency came out at over 76 per cent. from one quarter to full load at a direct-current voltage averaging 80, and over 80 per cent. for direct-current voltage averaging 112. The wave form of current through the rectifiers is beneficial to the batteries inasmuch as more time is given for chemical action, gassing is reduced, and the charge will be found more efficient than from a continuous current.

It is by placing a modern standard cell side by side with a production of the early days that the true progress made in the construction of accumulators is best realised. Evolution has been slow, radical departure from established lines being, not without reason, distrusted by users, but for all that every single feature bears evidence of marked improvements tending collectively to ensure greater uniformity, wider working range, and longer life. These objects were one by one successfully attained, yet subject still to the necessary careful daily attention being bestowed on the battery. The next step was to secure for the user absolute reliability and freedom from internal cell troubles with a minimum of supervision, and efforts in that direction also have been completely rewarded, even beyond expectations. As I have endeavoured to show, mechanical protection of electrodes has brought with it a substantial increase in the watt and ampere hour output obtainable from a given depth of formation, a combination of benefits realised by simple means, and without either straining the capabilities of cells or enhancing their cost. This latest advance in accumulator practice effectually removes the disadvantages of open spaces between plates, while retaining to the full extent their real objects—insulation, ample volume and free circulation of electrolyte—and it is safe to predict that all who have had experience with the new method will insist on its application in every future instance.

FORTHCOMING EVENTS.

FRIDAY, DEC. 15.

Electro-Harmonic Society.—At 8 p.m., smoking concert.

Institution of Civil Engineers (Students' Meeting).—At 8 p.m., "Tests of Street Illumination in Westminster," by Mr. E. E. Mann, B.Sc., Stud.Inst.C.E. Mr. E. W. Monkhouse, M.I.C.E., in the chair.

Junior Institution of Engineers.—At 8 p.m., "Electric Mains for Power Transmission Work," by Prof. John T. Morris, M.I.E.E. (member).

Physical Society.—7 to 10 p.m., Exhibition, Royal College of Science, South Kensington.

North-East Coast Institution of Engineers and Shipbuilders.—At 7.30 p.m., general meeting (at Newcastle-on-Tyne).

SATURDAY DEC. 16.

Junior Institution of Engineers.—At 10 a.m., visit to Messrs. Johnson and Phillips's works at Charlton.

Institution of Electrical Engineers (Manchester Local Section). At 2 p.m., students' visit to generating station.

MONDAY, DEC. 18.

Society of Arts.—At 8 p.m., "The Measurement of High-Frequency Currents and Electric Waves," by Dr. J. A. Fleming, D.Sc., F.R.S. (in continuation of previous courses on "Electric Oscillations and Electric Waves" and on "Hertzian Wave Telegraphy"). (Lecture IV.)

TUESDAY, DEC. 19.

Institution of Civil Engineers.—At 8 p.m., "Heat Economy in Factories," by Mr. H. A. Mavor, M.I.C.E.

WEDNESDAY, DEC. 20.

Institution of Civil Engineers.—At 2.30 p.m., students' visit to inspect the works in progress for the extension to Euston of the City and South London Railway.

Liverpool Engineering Society.—At 8 p.m., "Portland Cement," by Mr. H. K. G. Bamber.

Royal Meteorological Society.—At 7.30 p.m., papers on "Kite Observations from a Trawler in the North Sea," by Mr. George C. Simpson, B.Sc., F.R.Met.S.; "Investigation of the Upper Air in the West Indies by Means of Kites," by Mr. C. J. P. Cave, F.R.Met.S., and Mr. W. H. Dines, F.R.S.: "Temperature Observations during the Partial Solar Eclipse, Aug. 30, 1905," by Mr. W. H. Dines, F.R.S.; "Comparison between Glaisher's Factors and Ferrel's Psychrometric Formula," by Mr. J. R. Sutton, M.A., F.R.Met.S.; "A Rapid Method of Finding the Elastic Force of Aqueous Vapour, etc., from Dry and Wet Bulb Thermometer Readings," by Mr. John Ball, Ph.D., A.M.I.C.E.

Society of Arts.—At 8 p.m., "The Aerograph Method of Distributing Colour," by Mr. Charles L. Burdick.

FRIDAY, DEC. 22.

Institution of Electrical Engineers (Manchester Local Section).—At 7.30 p.m., "The Electrical Equipment of Automobiles," by Mr. J. C. Ward.

THE ELECTRICAL ENGINEERS, R.E. (VOLS).

Orders for week ending Dec. 23.

MONDAY, DEC. 18.—"A" Coy.—Recruit drill, 6 p.m.
Technical instruction, 7 p.m.

TUESDAY, DEC. 19.—"B" Coy.—Technical instruction, 7 p.m.
Medical inspection, recruits, 7 p.m.

WEDNESDAY, DEC. 20.—"A Badge" examination.

THURSDAY, DEC. 21.—"C" Coy.—Technical instruction, 7 p.m.

FRIDAY, DEC. 22.—"D" Coy.—Technical instruction, 7 p.m.

Headquarters will be closed from 11 p.m. on Friday, Dec. 22, 1905, until 10 a.m. on Monday, Jan. 1, 1906.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

TUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London and be crossed "Union Bank."*

THE LONDON COUNTY COUNCIL POWER BILL.

At last Tuesday's meeting of the London County Council a resolution was passed which authorises an application to Parliament which, if successful, will place in the hands of the Council the responsibility for the supply of electricity in bulk throughout Greater London. The scheme involved is described in outline in the report of the Highways Committee, which we reproduce in full elsewhere in this issue. We also give the report of the Finance Committee with its guarded conclusion. The question of municipal trading is one on which we have decided views, and on which we differ considerably from the present attitude of the Progressive majority of the Council. For example, we strongly disapprove of the Council undertaking the steamboat service on the Thames, and we consider that the failure of this service from a financial point of view was only too assured from the first. Other attempts have been made to render a remunerative service, and the records clearly showed that the limited length of season and, to use an electrical expression, the poor load factor did not allow of a steamboat service paying on the Thames. In the present instance, however, we have to express our agreement with the County Council's Power Bill, and think it well to give the reasons. In the first place, the Council is the financial agent of the local authorities owning electric supply undertakings within its area, and has thus evidence at its disposal that the artificial boundaries between the various metropolitan boroughs do not conduce to economy in supply. Again, looking forward to the time when the provisional orders held by the existing electric lighting companies will terminate, the Council will then be called upon to finance the undertakings if purchased by the local authorities under the Electric Lighting Acts. They are hence directly interested in the fact that developments in electric supply are now rendering the works purchasable by any one authority incomplete in themselves. For instance, it is absolutely certain that the largest number of local authorities will at the date in question be able to purchase distributing systems only. The few remaining authorities would be able to purchase not only the distributing systems within their areas, but also generating stations of a magnitude which would be many times too large for the districts in which they are situated. It is obvious, then, that electrical progress has so modified the conditions of supply from those presupposed when the Electric Lighting Acts of 1882 and 1888 were drafted, that the purchase clauses in these Acts are almost nullified. The spirit of the clauses would, however, be met if the County Council were to be made the purchasing authority for the (present) bulk supply stations. If this course is to be adopted, it seems also reasonable that the Council should be allowed at once to give that bulk supply which is required for cheap power distribution within the London area. There may still be a few expert station engineers who claim that such a bulk supply is not needed, and that they with their smaller stations can produce electricity at as cheap a rate as that at which electricity can be supplied to them from a very much larger station on the banks of the Thames. We are afraid, however, that their opinions must give way to the verdict of the two committees (the House of Lords Committee and the House of Commons Committee) who considered the Power Bills last year, and recommended that the Administrative County of London Power Bill should be passed. It seems to us that this verdict, which by a few hours only did not become law, should also reassure the Moderate party on the London County Council and the Finance Committee as to the financial prospects of the scheme. It will be

Digitized by Google

urged by some that the risk is one which, while a fit subject for private enterprise, should not be borne by the London ratepayers. This risk, as far as the local supply undertakings is concerned, is already borne by the London ratepayers. Again, it will be said that while the undertaking might be successful under the able guidance of Mr. C. H. Merz and his business friends from the North, it would be a financial failure like the Thames steamboat service if placed in the hands of a London County Council committee and the London County Council staff. The only reliable answer to this argument is the test of time, but a few figures, which, while not strictly comparable, are at least of interest, may give reason for our approval to the London County Council scheme. There is in the West of London a large tramway undertaking organised by Sir Clifton Robinson, whom we consider second to none in tramway organisation. From the figures given in Garcke's "Manual" for 1905, the London United Tramways undertaking had at the beginning of 1904 £1,890,063 of issued capital. They had also £1,031,000 of debentures, so that the undertaking, consisting then of some 37 miles of route, of which 35½ were electrified, had to pay interest on £2,921,063. This is equivalent to £78,676 per route mile. The system of electric traction employed by the company is the overhead trolley. In conjunction with these figures we would take those for the London County Council system for conduit tramways from the same volume and for the year ending March 31, 1904. For the tramways south of the Thames the Council had then spent £1,048,612 on electrical equipment, while the horse and cable systems purchased by the Council stood on their books at £1,075,617. This expenditure, amounting in all to £2,124,229, was represented by 43 miles of electrified line and averages £49,400 per mile of route. We do not pretend that these figures are comparable without making considerable adjustments which it is difficult to do in the space at our disposal at present. Allowing liberally for these adjustments we think it only fair to conclude that the Highways Committee, with the able assistance of their officials (Messrs. M. Fitzmaurice, A. L. C. Fell, and J. H. Rider) have proved that municipal tramway undertakings can be quite as economically installed and worked as company tramways. It remains to be noted that the Highways Committee have at present the charge over the scheme for bulk supply, for which powers are to be sought in the next parliamentary session.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

PERMEABILITY OF IRON.

SIR,—I have often had difficulty in collecting ideas as to what actually happens in the case of a piece of iron placed in a field of magnetic force, H. Perhaps the following will be useful to some of your readers.

It is accepted that a piece of iron is composed of molecules which are themselves small magnets or seats of magnetic force which is always of the same amount whatever state the iron is in, although when the iron is unmagnetised these molecules are so arranged among themselves that they neutralise each other's action. Now, when the iron is placed in a field of force, this field produces a righting action on the molecules, causing them to set themselves more or less in the direction of the applied force. The result is that the force due to the molecules (each one of which has its own definite field) intensifies or adds to the applied force so far as points inside the iron are concerned. When, however, we consider points outside the bar, it is seen that as the lines emerge and turn back to complete their circuit through the S-seeking end, the result is that everywhere there actually exists a field which is the resultant of two fields, one due to the applied force, and the other the force due to the constituent molecules.

Now, since outside the iron the two sets of forces are more or less in opposition, the result is a distorted weakened field, whilst inside the iron, where the fields are in the same direction, the resultant is a strengthened field. Hence it would appear better to say, *not that iron has a great permeability for lines of magnetic force in the sense that it collects them together into itself*, but rather that the intensified field inside the iron, and the weakened field outside, is due solely to the reaction of the field due to the constituent molecules on the original field.

Again, considering the statement that a magnet exerts a demagnetising effect on itself. In measuring permeability, the specimen is always placed to form part of a closed magnetic circuit, and then a certain definite value of H applied produces at any point of the bar a definite value of B. Now in the case considered of a bar of iron in a field, H, there is produced a value of B in the middle which is about the same as that which would be observed in a permeability test on the iron. Near the ends, however, the value of B is less than this amount by a quantity depending on the leakage of lines from points on the sides. This corresponds to saying that the value of B near the ends is less than that which would be observed in the same iron due to the same value of H in a permeability test; or, in other words, the value of B actually observed near the ends is that corresponding to a smaller value of H. Hence near the ends there is a tendency to demagnetise the iron produced by the ends.—Yours, etc.,

THOS. F. WALL.

Karlsruhe, Germany, November, 1905.

ANSWER TO QUESTION No. 820.

SIR,—I see in your correspondence columns in the current issue that Mr. P. Weil has written objecting to a statement I made in my answer to Question No. 820 in the issue for Nov. 10. Below is the particular portion of the query under consideration:

"Does not the above point to the suggestion that if two motors of similar amperage give same torque, but that one has lower power factor than the other, the lower power factor one is cheaper to run from consumer's standpoint?"

I think it will be seen that this is all a question of efficiency, for supposing the amperes and volts the same in both cases, as is stated, it is quite a possibility for one motor to have a certain power factor and a certain efficiency and for another motor differently designed to have a slightly lower power factor but a better all-round efficiency. I think this should make the matter clearer. I now quote the part of my answer objected to:

"Of course, if two motors can be found to do the same work, taking the same current at the same pressure, one having a lower power factor than the other, from the consumer's point of view it is advisable to use the one with the lower power factor, but it will be found that in reality there is very little to be made out of it this way, and it would be well to see that really you are improving the efficiency."

I think my present fuller explanation of my ideas should show that my former statement was perfectly correct, and in it I intended to imply what I still think, that there is not likely to be much gained by using a motor of lower power factor, if any, but still it is quite a possibility.—Yours, etc.,

ERNEST R. ALEXANDER.

BRAZING CAST IRON.

SIR,—Could you or any of your readers give me any information as to the flux and spelter used for brazing cast iron, and, also, if a patent, where I can obtain them? If you can give me any information I shall feel greatly indebted to you.—Yours, etc.

J. E. H.

Pretoria.

KNIFE SWITCHES.—Messrs. Ferranti Limited have sent us a catalogue of their single-pole double-throw quick-break knife switches for currents up to 2,500 amperes, also a list of their triple-pole single-throw quick-break knife switches for currents up to 1,000 amperes.

GLOVER'S HARDY PERENNIAL.

The copy of Glover's almanac for 1906, just to hand, is quite a gleam of sunshine to lighten the fog which pervades London at the time of writing this. There is much more original matter in the daily leaflets than in previous issues, and we are pleased to see that a refreshing humour pervades the bulk of the same. Take, for instance, the rules for laying electric cables which appear on the page for Jan. 4—a date when even the most hardened "first-footer" is supposed to have regained his equilibrium:

"On receiving a drum of cable at the station, have it lifted on to a lurry by means of a chain put round the cable itself. This fresco's the lead artistically."

"To unload the drum from a lurry—push it off. The makers like it. It is good for the drum."

"In running off lead-covered cable, select a course with plenty of sharp stones spread about. Put all the men on the end of the cable and drag it over the stones. If no stones are available, a heap of picks and shovels should be made. A live fire-devil will also be found useful."

"If possible, put a kink in the cable—four navvies should be able to do this in less than five minutes. Then straighten it out with a sledge-hammer and a plank."

"In laying solid, after the cable is pulled into the trench, let the gang walk on it for at least five minutes."

"If a pilot is being laid with a feeder, pull the pilot in first—then pull the feeder over it. This is good for the pilot."

"If a paper cable is to be cut, wait till the rain comes on. Then tape up with pure rubber and forget—this checks any tendency towards a too high insulation resistance."

The note at the bottom of the page that "Glover's make all types of joint-boxes" is a delicate hint that the above rules followed closely may lead to business. The sketch of

prehistoric cable-laying is excellent, and the striking likenesses of members of G——'s staff must appeal to all. The new proverb that "section pillars save sleeping draughts" is the outcome of experience as to the worries of main superintendents.

We conclude our extracts where the almanac begins. Thus for Jan. 1 we find the following 'On Business Prospects" (with apologies to Mr. Dooley): "An' phwat d'ye think is th' prospicts iv bisness this year an all?" asked Mr. Hennessy, wiping his mouth with his sleeve after drinking to Mr. Dooley. "It depends on phwat ye call bisness," replied Mr. Dooley. "William Shakespeare said, 'Bisness is bisness,' an' it may have been in his days; but he's wrong to-day. Bisness is profit; that's good bisness. If it's loss it ain't bisness at all; it's foolin'. Th' bisness iv last year was good f'r thim that profited be it, and bad f'r thim that didn't. Some iv th' folks 'll tell you that it was easy to git. So it may have been whin you're not anxious f'r a rayturn iv your money; but you can have too much iv that sort iv bisness. Others don't say nawthin', but perhaps they're th' folk who pulled off some iv the payin' orders. Th' people who write to th' pa-apers an' say they sold wan coil iv 1/18 to th' Muddlewick Borrow Council in competishun wid all th' other cablemakers forgit that their profit is mopped up be th' postage in th' letter. It's th' same wid sellin' as wid' buyin'; th' man who saved a few dollars be buyin' bad cable last year will lose 10 times th' amount be diggin' it up again this year. That's not bisness. But if he buys Glover's cables, that's ——." "Hold on," said Mr. Hennessy, "I asked ye f'r th' prospicts iv bisness f'r 1906" "Ask me again on December 31st," said Mr. Dooley, "an' I'll tell ye."

LONDON COUNTY COUNCIL POWER BILL.

The following is a joint report of the Parliamentary and Highways Committee of the London County Council on the supply of electrical energy in London and certain surrounding districts:

The Council on Nov. 14, 1905, resolved to seek statutory authority in the session of Parliament of 1906 to enable it to supply electrical energy in London and certain surrounding districts, and, in accordance with the terms of the resolution passed on that date, we now submit an outline of the scheme which we propose shall be adopted, and we place before the Council the draft of the Bill which has been framed to secure the objects in view. Our former report dealt generally with the importance of meeting more adequately the growing demands for the supply of electrical energy for general and for commercial use in a convenient manner and at cheap rates, and pointed out that it was generally recognised that this important object could only be secured by the establishment of a large central supply undertaking dealing with an extensive area.

Details of Proposed Scheme.

For some considerable time the Council's officers have been working under our direction upon the details of a scheme to be submitted to Parliament in regard to the Council's Bill of 1906. The work was entrusted to the chief officer of tramways and the tramways electrical engineer, but in view of the importance of the scheme, and in order that every detail in connection therewith should be put forward on a sound and practical basis, we thought it best that expert assistance should be retained to assist the Council's officers both in working out the scheme in its initial stages and by giving evidence in due course in support of the Council's Bill. For this purpose we secured the services of Sir William H. Preece, K.C.B., F.R.S., Past Pres.I.C.E., Mr. Robert Hammond, M.I.C.E., M.I.E.E., and Mr. John F. C. Snell, M.I.C.E., M.I.E.E. The officers have carefully considered the subject and have reported exhaustively thereon, and the several committees concerned have had personal interviews with the experts on the question. As the result, the officers, in consultation with the experts, have submitted to us a complete scheme, and they have been able to prove conclusively to our satisfaction that the scheme is feasible and practicable, and would not only be of great assistance to authorised distributors, but would also be of great public benefit. It should, we think, be pointed out that, under the scheme of the Administrative County of London and District Electric Power Company of last session, there was provision in the Bill to enable the company, under certain conditions, to compete in their respective areas with distributing undertakers. The scheme now submitted, however, has been framed on the basis of the Council co-operating with existing local authorities and companies and not competing with them by retailing energy without their consent. The proposals now put forward by us on these lines will, we are advised by the experts, enable electrical energy to be produced on the scale which it is now generally recognised is essential to economical generation, and supplied on terms as favourable as would be possible under any scheme.

The scheme provides for the temporary surplus of energy from the Council's tramways electricity generating station at Greenwich being supplied as required at the earliest possible date to some of the existing distributing undertakings. The

Digitized by Google

Council is aware that the erection of the second section of the Greenwich generating station is already in progress, and, in view of the arrangements which have been made with regard to the early reconstruction of the Council's (northern) tramways, the large number of new tramways which the Council is authorised to construct, and the suggested tramway extensions, the whole capacity of both portions of the generating station—namely, 34 000 kw. normal—will not within the next five or six years be required entirely for tramway purposes. Our suggestion is, therefore, that advantage should be taken of this fact to press forward the work on the second section of the Greenwich generating station in order that, as far as possible, this station may for a time, as stated, meet certain of the demands for electrical energy which cannot be dealt with by existing undertakings. In the meantime it is proposed that a station shall be erected on land by the riverside at Battersea to be specially acquired for the purpose. This station will in the main serve for the supply of energy to distributing undertakings, and ultimately for the purposes of the Council's own tramways. This will ensure a very economical form of supply. The resolution of the Council of Nov. 14, 1905, did not contain specific provision for the establishment of this station to be included in the Bill of 1906. The site suggested for the proposed new station is situated on the south bank of the Thames near Grosvenor-road railway bridge, being part of the land belonging to the Metropolitan Water Board, and is shown on the cartoon plan which will be hung in the Council-chamber when this report is considered on Dec. 12, 1905. The site proposed to be acquired has an area of about 15 acres, and is estimated to cost £120,000, which includes all legal and other charges. It is proposed that a portion of the site which will not be required for the bulk supply undertaking shall be utilised for tramways urposes.

It is proposed that on this site, which was formerly used by one of the London water companies, a station of 80,000 kw. normal capacity shall be erected. The scheme which we have considered provides for this station to be built in three stages as the demand for energy increases—namely, that the first two quarters, comprising together 40,000 kw. normal capacity, should be put in hand as soon as the necessary parliamentary powers shall have been obtained, and that the third and fourth sections, each of 20,000 kw. normal capacity, should be added either consecutively or together, according as the increase in the demand may justify. While the temporary supply is being given for bulk purposes from Greenwich, it is proposed to charge the bulk undertaking with the average cost, including a proper proportion of the capital charges. So soon, however, as a considerable section of the Battersea station shall have been completed it will be more economical, from the point of view of distribution, to supply energy to the tramways from both Battersea or Greenwich stations to meet the demands for tramway purposes from the western and eastern sections of the county respectively. We would point out that it has always been the Council's intention to provide two generating stations for the supply of electric power for its tramways, one at Greenwich in the eastern half of the county, and the other to serve the lines in the western half of the county, such further station to be erected on a site which the Council specially acquired for the purpose at Pimlico. Other arrangements have, however, now been made for the utilisation of the Pimlico site, and our present proposal to erect the new station at Battersea is merely an extension of the Council's original scheme, while the Battersea site will be more economical and convenient in some respects than the Pimlico site. Moreover, owing to the much larger scale on which energy is proposed to be supplied, it will be possible ultimately to generate such energy for tramway purposes at a lower cost than would have been practicable under the original scheme. It will be possible in the majority of cases to utilise the existing and proposed tramways sub-stations as bulk supply centres, a course which will effect very considerable economy both in regard to capital expenditure and cost of maintenance. While surplus electrical energy is being supplied from the Greenwich station for bulk purposes, the bulk supply undertaking will, it is suggested, provide the necessary cables and ducts for transmitting the energy to the supply centres.

By adopting this scheme it appears to us that very important advantages will be secured which would not be possible in the case of any proposal contemplating the installation of an entirely fresh undertaking.

In the report of the subject considered by the Council on Nov. 14, 1905, it was pointed out that one important objection raised against the Administrative County of London and District Electric Power Company Bill of last session was that enormous powers would have been conferred on private individuals in respect of the breaking-up of streets and the interference in other ways with public property. It seems to us to be obviously desirable that rights such as these should only be in the hands of a public authority; moreover, as the Council is itself from time to time laying electric mains in various parts of London for tramway purposes, considerable convenience and economy will be effected by placing the two services in the hands of the same central authority.

We realise that in the near future the growing demands for electrical energy within the area of supply must necessitate considerable capital expenditure in the provision of additional plant and equipment to meet such demands, and we are satisfied that such expenditure can be incurred to the greatest advantage by the Council being empowered to supply electrical energy upon the large scale proposed rather than by extensions of existing undertakings in a manner which does not permit of production on the most economical scale.

Provisions of Draft Bill.

A draft Bill has been prepared by the Parliamentary Committee, and a copy sent to each member of the Council. There are certain provisions of special importance to which we would direct attention;

1. *Area of Supply.*—The total area of supply dealt with comprises 387 square miles, including the county of London (117 square miles) and an area surrounding London comprising 270 square miles.

2. *Powers of Supply.*—Powers are sought to enable the Council to supply energy (*a*) to authorised distributors, (*b*) to large commercial undertakings, such as railways, tramways, canals, docks, and waterworks, for use either wholly within or partly within and partly without the area of supply, provided that the Council shall not furnish a supply for use wholly within the area in which any local authority or company is authorised to give a general supply of electrical energy, without the consent in writing of such local authority or company.

3. *Erection of Generating Station.*—Authority is proposed to be sought to enable the Council to erect a generating station on lands at Battersea which are scheduled to the Bill for the purpose.

The inclusion of the Bill of authority to acquire property for the generating station at Battersea makes it necessary to suspend the operation of standing orders Nos. A 161 and 162. As the Bill must be deposited on or before Dec. 16, 1905, it will also be necessary to suspend standing order No. A 27, as otherwise the matter could not be considered by the Council until Dec. 19. In the special circumstance we believe the Council will be prepared to take this course. The solicitor has already advised, under standing order No. A 163, with reference to the whole question of the Council's power to promote its Bill and to acquire property for tramways purposes.

4. *Co-Working with Tramways Undertaking.*—Necessary clauses are included in the Bill to enable the Council to work the bulk supply undertaking in conjunction with its tramways undertaking.

5. *Revision of Prices.*—Provision is included in the Bill for the revision, in certain circumstances, of the prices charged by authorised distributors.

6. *Financial Clauses.*—Various financial clauses have been inserted in the Bill providing, *inter alia*, for the establishment of a reserve fund, etc., which are necessary to place the undertaking on a sound financial basis. Provision is also made in the Bill with regard to the allocation of surplus revenue from the undertaking in such a manner as to provide, in our opinion, the greatest possible security compatible with benefit to the consumers.

Conference with Local Authorities and Companies.

The Council will remember that on Oct. 24, 1905, it authorised us to make arrangements for a conference with representatives of the City Corporation and the metropolitan borough councils to consider this question, and also to confer with the companies concerned as we might think fit. We held a conference on the subject with the London local authorities on Nov. 20, 1905, and after a very full discussion of the matter, the conference, by a large majority, passed the following resolution: "That this conference of borough councils approves of the introduction by the London County Council of a Bill for enabling it to supply electricity in bulk, subject to the interests of borough councils' existing undertakings being safeguarded and the details of the measure proving to be otherwise satisfactory."

The conference expressed the desire to have a further opportunity of meeting and conferring in greater detail upon the Council's proposals, and it was arranged that the necessary facilities should be given for this purpose, the conference either being summoned for a second meeting or a full communication being addressed to each borough council dealing in greater detail with the Council's scheme. In framing the draft Bill we have endeavoured in every way to meet the desire expressed by the authorised distributors who have already established distributing undertakings that they might be safeguarded, and we hope that the Bill in its present form will secure that object. In the event of the Council approving the Bill, we propose to forward it for consideration to each of the borough councils, and, if necessary, to arrange for a further conference. We have also been in communication with the local authorities outside the county of London who are affected by the Council's

Digitized by Google

proposals, and have had an opportunity of conferring with representatives of certain of the electric supply companies concerned.

We are continuing our negotiations with these authorities. In framing our scheme we have aimed at providing the most efficient and cheapest possible supply at the minimum cost, and, with a view to economy and to saving the Council capital expenditure, we have so drafted the Bill as to enable it to take advantage of any co-operation which existing undertakers in the proposed area may be prepared to give to the Council.

It is clear that if any such co-operation is forthcoming, as it would be given largely, at any rate, on capital already expended by such undertakers, it should lessen the Council's capital expenditure.

While we have not in our scheme counted upon any such co-operation, the saving to the Council in capital cost which might be effected thereby should not be disregarded in considering the scheme.

Financial Details of Scheme.

We have communicated with the Finance Committee in detail with reference to the scheme, and have placed before them all the facts relating thereto, in order to enable them to submit such report thereon to the Council as they may think fit.

Recommendations.

The recommendations which we now submit are :

(*a*) That the operation of standing order No. A 27, and of standing orders Nos. A 161 and 162, relating to the submission to the Council of schemes involving application to Parliament, be suspended on this occasion in order that the subjoined recommendation (*b*) may be considered.

(*b*) That authority be sought in the session of Parliament of 1906 to enable the Council to acquire compulsorily the site situated on the south bank of the River Thames at Battersea, shown in red colour on the plan submitted to the Highways Committee on Nov. 16, 1905, for the erection of an electricity generating station for the supply of electrical energy in bulk.

(*c*) That the London County Council (Electric Supply) Bill, 1906, submitted by the Parliamentary Committee, be approved; that the seal of the Council be affixed to a petition for leave to bring in the Bill; and that the Bill and petition, with any such necessary alterations (if any) in the Bill as the Parliamentary Committee may consider desirable, be deposited pursuant to the Standing Orders of Parliament.

T. B. NAPIER, Chairman of the Parliamentary Committee.
J. ALLEN BAKER, Chairman of the Highways Committee.

REPORT OF THE FINANCE COMMITTEE.

London County Council (Electricity Supply) Bill, 1906.

The Council will remember that in reporting on Nov. 14, 1905, on the proposal that the Council should seek powers in the next session of Parliament to supply electricity in bulk, we pointed out that we had not had before us any financial data to enable us to advise the Council as to the financial bearings of the proposal, and that it was, in our opinion, most desirable before the Council committed itself to the undertaking a definite scheme should be prepared and submitted.

In adopting the recommendations of the Highway Committee on this subject the Council added the following proviso : "Provided that before the introduction into Parliament of any Bill opportunity shall be afforded for full discussion in the Council of its provisions, especially as they affect the financial consequences of the scheme."

Since then a scheme has been prepared under the direction of the Highways Committee by the Council's officers, assisted by three well-known engineering experts, and we have been supplied with the details so far as they have been elaborated and with copies of the draft Bill, which the Council will be asked to approve.

We recognise that a great deal has been done by the Highways Committee in the limited time to furnish financial data, but we have not been afforded sufficient time to examine the estimates thoroughly, and as our report must be submitted on the 12th inst., we have confined ourselves to a consideration of the scheme from a broad financial point of view.

The two main financial considerations on which the Council will look to us for advice are (1) the estimate of capital outlay required, and (2) the possibility of the scheme being self-supporting.

1. *The Scheme of the Bill.*

We observe that the Bill is based upon the principle of supply to authorised undertakers and others throughout the area by agreement only, and that it is entirely of a permissive character. There will be no power for any authorised distributor or other person to demand a supply, and consequently no obligation on the Council to give it. The optional nature of the powers to be sought, if that option is maintained, may be held to lessen to a certain extent the financial risks which attend the undertaking.

The Bill appears to avoid competition with the existing undertakers (companies and local authorities) as regards the distribution of electricity, because it will not confer upon the Council the powers usually conferred on power companies enabling them to enter, under certain conditions, the districts of authorised distributors, or to bring pressure to bear upon such distributors to take a bulk supply. The result will be that the Council must look to existing distributors to push the development of the use of electricity for power purposes. We note, however, that Clause 35 of the Bill provides machinery which would enable manufacturers to obtain a supply through existing undertakers at cheaper prices than at present prevail, and would thus tend to assist the extension of the use of electricity.

Our attention has been directed to the extent to which powers of supply in the proposed area are already possessed and exercised by other bodies and companies. It seems that nearly the whole area is covered by local authorities or companies possessing provisional orders, and over a large part of the area bulk powers, practically identical with those proposed to be sought by the Council, have been granted by Parliament to certain power and electric companies.

The Council would not, therefore, possess any monopoly in the districts over which bulk powers are possessed by companies, but would have to meet the competition of those companies. In other districts, the Council will have no power to secure business except by coming to terms with the existing undertakers. In order to secure business, therefore, the Council must rely entirely on the cheapness of the price at which it can produce electricity. The significance of this fact, to which we refer again later on, will be apparent to the Council.

2. *Estimated Capital Outlay.*

The total capital powers sought by the Bill may be stated in round figures at £2,500,000. Details of this sum have been submitted to us. The expenditure of this amount is estimated to be spread over seven years to 1913. The amounts required in the first three years are estimated at

1907	£355 000
1908	545 000
1909	449,000

or £1,349,000 in all. The reduction of the proposed immediate capital outlay to these figures diminishes the objection which we feel to the increase in the Council's commitments on capital account, but the addition of £1,349,000 to the sums already required to be raised in the three years (1907-9) is a matter of important concern.

The establishment of a bulk undertaking by the Council for supplying the borough councils will, no doubt, reduce the amounts which these councils might otherwise require on loan for the extension of their generating plants, which sums would probably be borrowed from the Council and raised by the issue of London County consolidated stock. It is, however, necessary to point out that the erection of a large central bulk generating station involves the expenditure of a large amount of capital on transmission mains in order to convey the current to local centres, and that the net saving on capital outlay, although considerable, is reduced by this expenditure, the most important saving being made on working expenses. Moreover, the Council's bulk undertaking would deal with a much larger area than that covered by the undertakings of the metropolitan boroughs.

3. *Probable Financial Results of the Undertaking.*

We have had before us certain estimates of working costs and the probable growth of demand for electricity, but the figures are at present only of a provisional character, and we are advised that the publication of any estimates at the present stage might prejudice the Council's case before a committee of Parliament. We are consequently placed in a position of difficulty, because while we feel that the Council ought to have before it some means of judging as to the financial prospects of the scheme, we are unable for the reasons stated to submit any figures to the Council.

We propose to give further consideration to the estimates when they have been more fully worked out, and we may deem it necessary to report to the Council thereon at a later stage. It is essential, in our opinion, that whatever estimates are placed before Parliament in support of the Bill should have been thoroughly scrutinised by us, because such estimates practically commit the Council. It is true that before any liability is incurred and money voted by the Council under powers which may be obtained from Parliament estimates would have to be submitted, when the whole question could be thoroughly considered, but the Council would find itself, as it has done in other cases, committed in the main to the scheme and estimates already placed before Parliament. The Council will, therefore, see the necessity of the matter being thoroughly considered now.

While not in a position to make public at this stage any of the figures submitted to us, we may say that, from such consideration as we have been able to give to them, we anticipate that the Council would be able from one or more large central stations to generate electricity at a cheaper rate than it is now being produced at the small generating stations of most of the existing undertakers, and, moreover, that the Council, by

Digitized by Google

working the scheme in conjunction with its tramway undertaking, would be in a favourable position for supplying energy in bulk and at a reasonable price. We cannot at present say whether the Council could supply at such low prices as would enable it to successfully compete for business with the large power and electric companies who possess powers of supply in bulk throughout a large part of the proposed area. This is, after all, the crucial question, because, as already pointed out, it does not appear that the Council will possess any monopoly, but will be mainly dependent for business, so far as we can see, upon its ability to sell at a price which would induce existing undertakers to take a supply from it. The selling price from time to time will depend upon a variety of considerations which at present are undetermined. A good deal will turn upon the load factor which can be obtained and the amount of support to be received from authorised undertakers. The price later on may be affected by the progress of knowledge in the methods of generating and transmitting electrical energy and the action of other companies and bodies, which cannot be foreseen.

The position which the Council will occupy in this matter has engaged our serious attention, and we cannot help thinking that the Council ought, before embarking capital in such an enterprise, to have some further security than it will apparently possess. We are not prepared at the moment to say what the nature of the security should be, but it would appear to lie in the direction of the Council making suitable and permanent arrangements with the existing undertakers. Having regard to all the contingencies and risks inseparable from an undertaking of this kind, we think that the Council will agree as to the expediency of seeking some security for its undertaking, particularly as we have not at present been supplied with definite information as to the amount of support which the Council is likely to receive.

Whatever conclusion may hereafter be arrived at as to the probable ultimate financial results of such an undertaking as the Council may obtain power to establish, we are of opinion that the Council must face the probability that during the early years the undertaking will show a deficiency which will have to be made good out of the rates, because from its nature some years must elapse before a sufficiently large amount of business can be secured to make the concern profitable.

4. *The Financial Provisions of the Bill.*

We have considered the purely financial provisions of the Bill, which, speaking generally, are, in our opinion, satisfactory. There are, however, four financial clauses on which the Council will desire to have our observations.

Clause 36 (2) of the Bill provides that the Council shall not be bound to commence payments into the sinking fund until the expiration of five years from the end of the financial year current at the passing of the Act. A period of seven years was allowed in the cases of the Holborn to Strand and Westminster improvements, but we concur in the proposal to ask for a postponement of five years only in the present case, and think that the assent of the Treasury may probably be obtained to this clause. We may point out that debt will have to be repaid, after payments to the sinking fund commence, in periods less than the usual by the number of years during which payments have been postponed. Thus capital expenditure, which would be repaid in 59 or 25 years in the ordinary way, will have to be repaid in 54 or 20 years after the expiration of the five years' postponement allowed.

Clause 42 provides that the Council may pay (to an amount not exceeding £105,000) out of borrowed money interest paid on capital during construction. This would be a novel power so far as the Council is concerned. We approached the Treasury with a similar proposal in connection with the Holborn to Strand Improvement in 1899, but their Lordships would not assent to it. We have, however, since our former report was before the Council, ascertained that there have been in recent years cases in which provincial corporations have obtained this power in the case of large water and dock undertakings which occupy many years in construction, and necessitate the payment of large sums of interest on capital before the undertakings produce any revenue. The views of the Treasury may consequently be somewhat modified, but the Council cannot rely upon obtaining this concession.

The Bill provides (Clause 39) for the creation of a reserve fund. No limit to the amount of the fund is fixed by the Bill, and it will be in the power of the Council to apply surplus revenue to build up an adequate reserve fund. Under Clause 38, which provides for the order in which revenue shall be applied, the provision of a reserve fund follows payment of working expenses and debt charges. Provision is then made for the repayment to the county fund of any deficiencies made good in previous years out of the county rate, but under the provisions of the Bill the Council is not bound to so repay the county fund in the first year in which a surplus is available, it being left open to the Council to use such surplus to form a reserve fund or to reduce prices. After deficiencies met out of the county rate have been made good the Council may, out of any surplus, take a sum not exceeding in any year 5 per cent. on the aggregate capital expenditure for the benefit of the London ratepayer, who, we may remind the Council, will, if the Bill passes in its present form, bear the whole financial risk of an undertaking dealing with an area over three times that of the county of London. Any surplus remaining after this 5 per cent. must be applied to reduction of charges, the Council being entitled to carry forward such balance on revenue account as is reasonably necessary.

The last clause to which we think attention should be called is Clause 43, which provides that the Council shall, after five years from commencing to supply from any generating station erected under the powers now sought, and each three years thereafter, fix the prices to be charged (other than those contained in any agreement or contract), so that, as far as practicable, no charge shall fall upon the county rate.

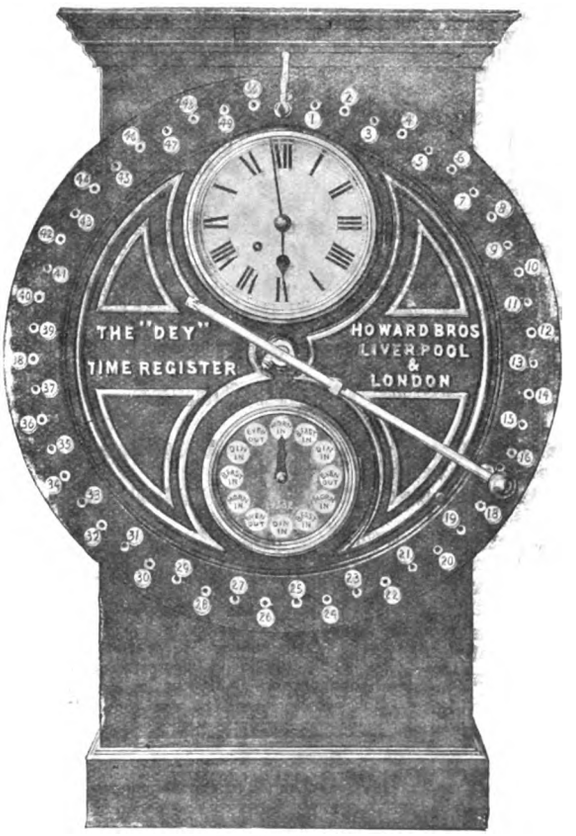
In conclusion, and looking to all the circumstances, we are impressed with the fact that financial risks are inseparable from an enterprise of this kind covering so large an area, and that if such risks mature, the burden will fall entirely on the ratepayers of London. Bearing this in mind, we are of opinion that if on the grounds of general policy the Council should finally decide to promote the Bill, every endeavour should be made to make arrangements with existing undertakers for the supply to them by the Council of electrical energy in bulk.

(Signed) WELBY, Chairman.

TRADE NOTICES AND NOVELTIES

The Dey Time Register.

Now that more attention is being given by employers of labour in this country to up-to-date methods, we need not apologise for referring again to the Dey time register, an excellent device for accomplishing its purpose. The chief feature of this machine is the weekly time and wages sheet, which is arranged to take the time of 50 employés, giving their numbers in numerical order with the whole of their "ingoings" and "outgoings" for the week on the line opposite their numbers, having extension columns for writing in the total number of hours worked, rate, amounts to pay, etc. These sheets can be ruled and printed to suit any requirements, giving "overtime in and out," and so forth, and are made in four sizes to fit their respective machines, for 50 hands, 100, 150, and 200. The weekly sheets require no transcribing, forming a complete time and wages book when filed in a guard book or cover. Daily sheets can also be used on the machine, but the weekly sheets are chiefly in demand. Further, an attachment can be fixed for the purpose of recording on cards the time spent by employés on particular jobs for the purpose of cost keeping; also for taking the time of messengers, carters, etc., on journeys. This attachment does not in any way interfere with the ordinary work of the machine for time-keeping, but has the advantage of time keeping and cost keeping on one machine. The latest form of this machine is entirely automatic and requires no attention for a week, the columns for "in" and



The Dey Time Register.

Digitized by Google

"out" and from day to day being moved automatically. It is manufactured in England throughout by Messrs. Howard Bros., of 100c, Queen Victoria-street, London, E.C., and Liverpool, who have also recently introduced an automatic card machine for cost-keeping purposes which is very small and compact, requiring no attention for a week.

Catalogues, etc.

LUMINOUS ELECTRIC RADIATORS.—From Messrs. Baxendale and Co., Miller-street, Manchester, we have a list of their luminous electric radiators, including several entirely new designs.

STEAM PLANT.—We are indebted to Messrs. Mechan and Sons, Limited, Glasgow, for some pamphlets describing the "steam superheaters" of various types, "steam dryers," and "oil separators," which they manufacture under Prof. Watkinson's patents. The information given is both interesting and instructive, but cannot be dealt with in the space now at our disposal.

THE ELECTRICAL COMPANY'S PUBLICATIONS.—We have received copies of the following from the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C.: Pamphlet No. 174, "Electricity in Shipbuilding Yards"; Leaflet No. 151/1, "How to Make Electric Light Cheaper by Means of Nernst Lamps"; Leaflet No. 191, "Region Small Arc Lamps"; Leaflet No. 194, "Small Motors."

HODGSON, WRIGHT, AND WOOD'S MANUFACTURES.—A number of lists are to hand from Messrs. Hodgson, Wright, and Wood, Century Works, Halifax, as follows: List No. 9 "main" and "battery charge and discharge" switches; List No. 10, "shunt-wound continuous-current protected motors"; List No. 11, "shunt or compound wound continuous current dynamos"; List No. 12, "shunt-wound continuous-current open-type motors"; List No. 13, "single," "two and three phase" motors fitted with ball bearings; List No. 14, "starting switches."

ANGOLD ARC LAMPS.—The General Electric Company, Limited, 71, Queen Victoria-street, London, E.C., are just issuing a new booklet dealing with their Angold arc lamps and accessories. We notice the inclusion of a new pattern of lamp. This is of the twin-carbon type, and is suitable for indoor or outdoor lighting on high-voltage circuits, where lamps are required to run independently of each other. Mention may also be made here of a new pattern of balancing coil for use with alternating-current enclosed-type arc lamps. Prices have been reduced both for the lamps and accessories.

SHOWCARDS.—From the Simplex Steel Conduit Company, Limited, Westinghouse Building, London, W.C., we have received an artistically designed showcard giving a list of contracts where the company's material has been used during the first eight months of this year; also a small print of a large trade mark showcard, 21in. by 15in., which they are sending out to customers who require something for display purposes. The first-mentioned shows a record of work of which the company may well be proud. We understand they will be pleased to forward a copy to any of our readers who may like to have one.

APPOINTMENTS VACANT.

Electrical Engineer, Radcliffe Urban District Council. Salary, £150 to £172 per annum.

Assistant Lecturer and Demonstrator in Electrical Engineering, Leeds University. Salary, £175 a year.

Electrical Engineer, Pontypridd Urban District Council. Salary £91 per annum. Applications to the Clerk by Dec. 27.

Representative, South Wales district, for the sale of direct and alternating motors. Apply, Box F. Z., *Electrical Engineer* Office.

Shift Engineer, London station. Salary to commence, £2 per week. Applications to Box 574, Sell's Advertising Offices, London, E.C.

Junior Charge Engineer. Salary, 30s. per week, rising to 35s. Applications to the Borough Electrical Engineer, 335, High-street, Cheltenham.

NEW COMMITTEES.

The following additional committees have been appointed:

BACUP.—Electricity and Tramways—Aldermen Astley, Hardman, Hoyle, and Law; Councillors Mawdsley, Worwick, Green, and Greaves.

BERMONDSEY.—Electric Lighting—Councillor Pridman, chairman.

GILLINGHAM.—Electric Light and Baths—Councillor Holmes reappointed chairman.

HANLEY. — Electric Lighting — Alderman Costes, chairman; Councillor Schofield, vice-chairman; the Mayor; Aldermen Ellis, Hampton, Huntbach, O'Keefe, and Shirley; Councillors Bickley, Blackburn, Bratton, Jackson, J. Harvey, Kirkham, Mayer, Nuttall, H. B. Shirley, and Stanley.

HOVE.—Lighting—Alderman Clark; Councillors Abell, Bull, Davies, Genner, Mead, Nye, and Sayers.

YARMOUTH.—Electricity—Councillor Johnson, chairman; Councillor Nudd, mayor; Aldermen Mayo, Durrant, and Suffling; Councillors Arnott Bayfield, Beevor, Bellamy, Chamberlain, Freeman, Knights, Lawrance, Lee, Nightingale, Pitchers, and Traynier. Tramways—Alderman Arnold, chairman; the Mayor; Aldermen Mayo and Suffling; Councillors Arnott, Bayfield, Beevor, Grimble, W. H. Green, Johnson, Lawrance, Norfolk, Pitchers, Rushmer, F. J. W. Salmon, J. T. C. Salmon, and Tyrrell.

LEGAL INTELLIGENCE.

SWANSEA TELEPHONES.

An appeal is being heard by Lords Justices Vaughan-Williams, Stirling, and Cozens-Hardy by the National Telephone Co. from the judgment of Mr. Justice Buckley, who, in an action by the Mayor and Corporation of Swansea against the company to enforce the giving of "reasonable facilities for intercommunication" with their telephonic subscribers, held that the facilities offered by the company amounted to a refusal to give any facility at all within the meaning of the new Telegraphs Act of 1899.

The case for the company was that the Corporation demanded intercommunication in a way which would destroy both systems, and that it had offered to do the work in an efficient and economical manner, which would at the same time enable it to fulfil its obligations to its own subscribers. It was also argued that if Mr. Justice Buckley's decision were upheld, other corporations all over the country would start rival systems, and the business of the company would be ruined.

Mr. BUCKMASTER, K.C., who appeared for the Corporation of Swansea, said that the company had absolutely declined to allow the Corporation's subscribers to communicate with theirs except upon the terms that the Corporation should run from their central exchange at Swansea to each one of the company's sub-exchanges a new and totally independent route for the purpose of carrying all the messages that originated upon their system. They declined to allow the Corporation to use any part whatever of their junction lines or, as he understood it, their local sub-exchanges except for the purpose of putting in a wire.

Lord JUSTICE VAUGHAN-WILLIAMS pointed out that there was a demand on one side and an offer on the other, and the Court might come to the conclusion that both of the parties were wrong—that the Corporation had no right to ask for what they had asked, and that the offer of the Company was not sufficient.

Mr. BUCKMASTER said that if the Court held that the offer was not sufficient that would meet his point. The whole question was whether the company had refused to give proper facilities. That was all the Court had now to consider, though there might be further questions to be dealt with later. Everyone appreciated that this was not a case that stood by itself. It was one of the first cases in which corporations had been attempting to use the powers conferred upon them by the Act, and the conditions under which this communication was going to be made would affect not merely this Corporation, but corporations all over the kingdom that had obtained licenses. He could not help thinking that the case was being presented by the company in the interests of its shareholders, while the Act thought of the subscribers. What the company proposed was most unreasonable. It was quite clear that if the arrangement suggested by the company were adopted, the two systems would never come into communication. An obligation had been imposed by the Legislature on the company by reason of the fact that its monopoly had been extended, and the object of the Act was to provide that advantages should accrue to the public, and that it should not be possible for the company to withhold from the public the benefit of the use of its system simply because they had become members of another system. What the Act provided for was intercommunication of subscribers and not of systems. The company said that would make it difficult and would throw expense upon it, but the Act did not mind that. It only considered how it could best arrange that two sets of subscribers should get intercommunication. There was nothing unfair in that. It was said that the company's subscribers outnumbered those of the Corporation in the ratio of 1,500 to 700. If the company put its 1,500 subscribers into communication with the other 700, the Corporation would have to provide for just twice as much traffic as the company would, and if they had not made proper provision to take the increased traffic, they would have to do just twice as much work in the way of laying extra wires as the company would have to do.

Mr. ASTBURY, K.C., for the company, said that this was the first case that had come up for decision under the New Telegraphs Act, 1899, which gave a borough council the right under certain circumstances to compete with the National Telephone Co. The borough of Swansea had obtained a license until 1923, and had called upon the Telephone Co. to give what the Act called "reasonable facilities" for what was described as "restricted intercommunication." All that meant was, he submitted, that subscribers to one system should have an opportunity of communicating with the subscribers of the other, and not, as Mr. Justice Buckley held, that one system should be joined to the other. It was of extreme importance to the Telephone Co. that it should see that these facilities were given in such a way as would not disintegrate and ruin the system which was called upon to grant the facilities. The case was of vast importance to the company, for if Mr. Justice Buckley's construction of the Act was correct its business would, in the event of other claims of the same nature arising throughout the country, be lamentably disintegrated. There were many ways in which the facilities might be given, and all the Act said was that they should be reasonable. The Telephone Co. had taken the very best expert opinion, and claimed that by means of the facilities offered the work would be done efficiently and at the same time without unnecessary disturbance to its own system. The Corporation demanded intercommunication in a particular way and by particular means which the company said would destroy both systems. The learned judge had expressed himself strongly in favour of the Corporation's demand, and had gone so far as to hold that the facilities offered by the company amounted to a refusal to give any facilities at all within the meaning of the Act. If that decision stood, corporations all over the country would start telephone systems in rivalry with the company. That was

Digitized by Google

what the company wanted to protect itself against. The company had 12 exchanges in Swansea and the Corporation now had five. The latter claimed that all they had to do was to bring a great bundle of cables up to the company's central exchange and demand that the company should put them on to the switchboards. Then the Corporation said if any of their subscribers wanted to telephone to any of the company's exchanges, the company would have to lay the necessary junctions and do the necessary work to take their messages through the central office. The company, on the other hand, said that the Corporation must carry their messages up to the switchboard to which their subscribers were connected.

The hearing was not concluded when we went to press.

BLACKPOOL-FLEETWOOD TRAMWAY RATING APPEAL.

In the King's Bench Division on Wednesday the case of the Blackpool and Fleetwood Tramroad Co. *v.* the Thornton Urban District Council was heard on the appeal from a decision of Quarter Sessions upholding a rate. In July, 1904, the Thornton Urban Council made a general rate, in which the appellants were rated at £706 on the tramway track in Cleveleys, £105 on a waiting-room, and £56 on an accumulator-house. The company appealed on the ground that they had been rated on the full annual value, whereas, as they contended, they were entitled to be rately on only one-fourth of the net annual value, the line being a railway. It was stated that the line was constructed wholly on land belonging to the company, and was hedged in from other land except where the line crossed the public roads. The appellants paid passenger duty, and they submitted that the line could only be worked as a railway. The justices were of opinion that the lands were not used as a railway within the meaning of Section 211 of the Public Health Act, 1875, and dismissed the appeal.

The LORD CHIEF JUSTICE said there was such a slight shade of difference between railways and tramways that it was sometimes difficult to distinguish them, but on the whole he was of opinion that the justices were right in this case, and that the appeal must, therefore, be dismissed with costs.

CARDIFF TRAM COLLISION.

At Cardiff County Court on Friday last (before Judge Owen and a jury) an action was heard in which Joseph Edward Coakley claimed £50 from the Cardiff Corporation in respect of injuries sustained by his little girl, who was knocked down by an electric car in Cathays in September last.

In the course of the evidence the car was said to have been running at top speed.

"What sort of speed is that?" queried his Honour. "There is a limit to everything—even to the speed of a motorcar."

Plaintiff's case, as represented by counsel and witnesses, was that the child came to grief as she was running across the tramway line in Orwys-road with some little boys, one of whom was her brother, to pick up a piece of coal. The injuries sustained were bruises on the left leg and left side of the head. A medical man said the child's clothes were torn and cut. There was a wound on the thigh 4in. or 5in. long. At one time it was a question whether the injuries would be permanent, but the little one had, happily, recovered.

It was alleged that the car pulled up almost immediately, and in defence it was submitted there was no case to go to the jury, and that there was contributory negligence on the child's part and on the part of the parents.

JAMES LENTHALL, the driver, denied the top-speed statement, and said he took every precaution—rang the bell, and the car was at once pulled up. The child was "impelled" in the direction in which she was going. She passed in front of the car, and was between the rails when she was knocked down on the off side. The girl showed no indication of making for the track, and were he to stop for every child he would never make any progress.

After more evidence HIS HONOUR said this was the first action against the city of Cardiff he had had the honour to try. The Corporation had no further right beyond laying the tramways to the King's highway. If an old woman sat in front of a car she was entitled to do it, and if the car ran over her the only remedy was to summon her for obstruction. His Honour said the question was a simple one, and put it to the jury whether the driver did all that a prudent man should have done.

The jury retired, and on their return brought in a verdict for the plaintiff for £50, the amount claimed.

CLAIMS AGAINST THE MERTHYR ELECTRIC TRACTION CO.

Two claims for damages were brought against the Merthyr Electric Traction Co. at Merthyr County Court on Friday last. In the first case the plaintiff, Thomas Thomas, sought to be compensated for damage done to a pony and cart, which were run into on the Brecon road by an electric car on July 12 last. His Honour found for the defendants, holding that there had been no negligence.

The plaintiff in the second case was a collier's boy, named Joshua Price, who claimed £5 in respect of injuries sustained through being struck with the handle of the ratchet brake whilst boarding a workmen's car at Pontmorlais on June 9, and judgment was given for the plaintiff for the amount claimed, with costs.

TELEPHONE DISPUTE.

At Brighton County Court on Friday last, before his Honour Judge Scully, the Corporation of Brighton sued Mr. S. G. Watson, surgeon, for £13. 14s. 7d. for fees, etc., in connection with the Corporation telephone service, incurred between June 1, 1904, and April 13, 1905.

The assistant manager to the Brighton Corporation telephone department, was first called on behalf of the plaintiffs, and he stated that on July 8, 1903, defendant sent in an application form for a private line.

The defence objected to the document being put in submitting that it was a memorandum containing all the terms of the contract, and ought, therefore, to have been stamped, and that, being unstamped, it could not be accepted by his Honour.

His Honour held that the document was not one that required a stamp.

Every item of the claim was then admitted, with the exception of one of £3. 5s. 6d. for moving the telephone from Islingword-road to Elm-grove.

Defendant explained that the Corporation would not accept less than the full amount, although he offered to pay all other charges except the disputed item.

Evidence as to the correctness of the disputed charge having been given, and Mr. Gardner having stated that the Corporation charged cost price for the work and materials, his Honour gave judgment for the plaintiffs with costs.

TELEPHONE CONTRACT.

The National Telephone Co. sued Mr. Amatt at the Portsmouth County Court on the 7th inst. for £3 for a year's contract for a two-party line telephone, and 2s. 6d. for the contract stamp and 8½. for postal facilities. Defendant said he did not make payment in advance because he did not receive plaintiffs' letters in time, and he was much inconvenienced at having the telephone suddenly cut off. Some stringent strictures were made by his Honour Judge Gye on the terms of the contract, and the company came in for much criticism. Judgment was given for plaintiffs for £3, and an order for 10s. a month was made.

COMPANIES' MEETINGS AND REPORTS

ARON ELECTRICITY METER.

The eighth ordinary general meeting of this Company was held on the 8th inst. at Winchester House under the presidency of Mr. H. Hirst, M.I.E.E., the chairman of the Company.

In moving the adoption of the report (a copy of which appeared in our last week's issue), the CHAIRMAN said the stock of meters, clocks, and meter parts, etc., stood over £6,000. That was due to two reasons: firstly, they had done an increased business; secondly, this stock had increased, particularly in their German business. There had been, during the last few months, serious labour troubles going on in Germany, and Prof. Aron did not know which industry might next be affected, and as he was drawing his supplies from various industries, he thought it wise, so that the Company should not suffer more than was necessary, to fill up his stock to the best of his ability. The meter business, as well as the electrical business generally, was (said the chairman) in a constant state of evolution, and it would be no use sitting tight on old patents if they did not constantly employ their staff, and wish to learn what others were doing and try to get ahead of them. The results of the fairly satisfactory report were due principally to the business carried on in Berlin, at the factory in Schweidnitz, and at the Company's branch in Vienna. Mr. Hirst said that in Germany Prof. Aron had worked very hard and very economically; he had used his influence even to the extent of obtaining orders by travelling a great deal himself. They had sold in Germany more meters than at any time during the existence of the Company. At Schweidnitz they had a most careful manager, who, by great care and economy had enabled the factory at Schweidnitz to make such reductions as were necessary in order to counteract the cheaper price at which they had to sell the meters last year. At Vienna for a year or two the business was receding, but was now recuperating. He told the shareholders that the directors had spent a lot of money to produce cheap meters, and he said that their small meter was finding favour. The business generally done in this country had been in connection with meters and apparatus where the price was not so important an object—double tariff meters, meters for standardising stations, standard instruments, and traction meters. He was particularly glad to say that some railway companies and traction companies were beginning to appreciate the importance of putting meters on their engines and cars in order to check the energy required for each engine or car, and to check the drivers as against each other. If that once finds popular favour, he thought that their meter was the only one that would give satisfaction. Continuing, he said: "We are not depending upon one type only, and in that direction we wish to continue. I do not even mind stating, although I am not particularly authorised, that we are at present studying petrol traction and the development of autocars, for the purpose of seeing whether we cannot find a useful outlet for our unemployed capital, on which we have sat tight up to the present, until our original business is again in a healthy state. We are prepared to spend a reasonable amount of money in this direction, and we hope next year to be able to put something tangible before you. If we have no results, we shall not be any the worse off."

Sir JAMES PENDER, Bart., seconded the motion.

The motion was carried unanimously.

It was resolved that the dividend of 4½ per cent. on account of preference dividend in arrear, as recommended by the directors, be paid.

FRASER AND CHALMERS.

The ordinary general meeting of the shareholders of this Company was held on the 11th inst. in London. The chairman, Sir JULIUS

Digitized by Google

WERNHER, Bart., in moving the adoption of the report (copy of which appeared in our issue of the 1st inst.) regretted that the loss of revenue from the American company prevented the payment of the same dividend as the previous year. The reason for the falling off in the American business was, he explained, that the business had undergone a change which required large and extensive modifications, which had to be met out of the profits. The business at Erith has been as satisfactory as it was the year before. The Chairman said they had never been more busy than in the last six months of the year under review, and that they had been equally busy in the first half of the current year, while the prospects for the remaining portion of the year in regard to business are equally good. The fall in revenue from the American company amounted to nearly 4 per cent., but the directors decided not to reduce the dividend by 4 per cent., but to pay only 3 per cent. less. Continuing, Sir Julius Wernher said he did not consider that there was anything very alarming in that, because the large profits which were carried forward were real profits made on the business done in the past. The directors had not distributed by way of dividend the profits in full, as their idea had always been to keep a certain proportion in hand in order that they might be in a position to equalise the dividends should ever a shortfall arise. Another consideration which decided the directors to depart from their very conservative methods and to pay £2,000 out of the carry forward, was that the prospects of the current year were decidedly encouraging, so that they did not think that that encroachment on the carry forward would affect the next dividend.

Mr. R. ENGLISH seconded the resolution, which was then put to the meeting and carried unanimously.

A final dividend of 4 per cent., making 7 per cent. for the year, on the ordinary shares was declared; the retiring directors and auditors were re-elected; and votes of thanks were passed to the chairman, directors, manager, agents, and the staff of the Company for their services.

BRITISH WESTINGHOUSE ELECTRIC AND MANUFACTURING.

The report of this Company for the year ended July 31, 1905, to be submitted at the meeting on the 18th inst., shows a gross profit of £113,409. After providing for debenture and loan interest, depreciation, and the special expenditure enumerated below, a loss of £15,407. 10s. 10d. is shown after deducting the balance of £2,810 brought forward from last year. The special disbursements referred to are: exceptional expenditure under the Mersey railway contract, £43,550; balance of exhibition and sundry expenditures brought forward on July 31, 1904, now written off, £5,340; proportion applicable to the current year of excess cost and experimental expenditure on manufacture of new types of apparatus during that period, £25 000. Following the course indicated by the directors in last year's report, care has been exercised to have the works equipment efficiently maintained, and, in addition, a very considerable sum has been charged to profit and loss account for the maintenance of large machine tools and machinery, while all patterns and drawings, together with patents acquired, have equally been charged to profit and loss account. In view of this, the directors are of opinion that the sum of £16,500 provided for depreciation, which includes £5 000 in respect of the buildings themselves, is adequate. The balance of £225,000 of 4 per cent. mortgage debenture stock available for issue has been sold to the American Westinghouse Co., to be taken at 95 per cent. in the course of the year 1906. The volume of output from the works during the year under review was considerably in excess of that for the previous year, and a large saving in manufacturing costs and in selling and general expenses was effected. Competition is still very keen, and seriously affects the Company's business and outlook, but it is hoped by the directors that, with the revival in trade, this condition may improve.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS.

The report of this Company for the year ended Sept. 30, 1905, to be presented at the meeting on the 19th inst., shows, after provision for doubtful debts, a net profit of £51,729. Adding £53 274 brought forward, and deducting £12 500 interim dividend paid in June, there remains a disposable balance of £92,503. The directors recommend a dividend of 15s. a share, making a total payment of 10 per cent. for the year, and leaving £55,003 to be carried forward. The general business of the Company shows an increase compared with last year, and although the price of raw material is still very high, the fluctuations have not been great, and therefore better prices have been obtained for manufactured goods. The cable department, besides having other smaller work in hand, is at present engaged in the manufacture of 1 300 nautical miles of submarine telegraph cable, which will be laid by the Company's cable steamer "Silvertown" between Shanghai and Manilla in March next. The "Dacia" and "Buccaneer" have been employed in cable repairing work during the year, and the latter is at present under charter. The works at Silvertown and Persan have been maintained in their usual state of efficiency, but considerable expenditure must still be made at Persan to provide for the economical production of goods for the French market.

ISLE OF THANET ELECTRIC TRAMWAYS AND LIGHTING

The report of this Company for the year ended Sept. 30 last, to be submitted to the meeting on the 20th inst., states that traffic receipts show a reduction of £2,924 and the sale of electricity an increase of £490. The directors regret that the profits have only enabled them to pay the preference dividend to March 1, 1905, and they have carried forward the balance of revenue, £1,047. Two accidents took place during the year. The Company was fully insured against third-party risks, and therefore lost nothing by personal claims, but the accidents had a detrimental effect on the traffic receipts. Acting upon the suggestion contained in the report of Colonel von Donop upon the accident at Madeira Hill last August, the Company have made arrangements for exchanging drivers before arriving at Madeira Hill and the other steep gradients, so that in future none but their most experienced men will operate the cars on these parts of the system. The sum of £418, being the cost incurred in the unsuccessful promotion of a lighting order for Ramsgate, has been charged against revenue.

BRITISH ELECTRIC TRACTION.

The directors in their interim report state that since the date of the last report about 17½ miles of new or reconstructed tramways or light railways have been opened for traffic by electric traction, and the Bombay horse tramways, of about 17 miles, have been added to the list of associated undertakings. The total mileage of tramways, railways, and omnibus routes is now 439 miles, and the total traffic receipts of all the associated undertakings for the current year are estimated at £1,400,000, as compared with £1,254,061 for 1904. Electrical lines are now under construction at Penge and Croydon to Mitcham, near London, at Cavehill, near Belfast, in Middlesex (forming part of the large system of the Metropolitan Electric Tramways Co.), and in the Birmingham district. In spite of the fact that the Company has sold its interests in several undertakings to local authorities and others, upon which the return for 1904 was about £12,000, the directors expect that the aggregate return for the current year upon the Company's investments will be maintained. The directors anticipate that satisfactory profits will be made by the Company before the closing of the books on March 31 next, but, as the substantial profit receivable in shares of the Bombay Electric Supply and Tramways Co. has not actually been received at this date, the directors prefer not to declare an interim dividend on the ordinary shares for the present half-year. The Bombay company has successfully raised £600 000 in debenture stock and £600,000 in 6 per cent. preference shares, thus enabling this Company to meet its main obligations in regard to this enterprise. Energetic steps are being taken to carry out the conversion of the tramways to electric traction and to enable the Bombay company to deal effectively with the supply of electric light and power, for which there will be a large demand. The volume of business carried out by the Brush Electrical Engineering Co. during the current year shows a considerable increase. The rolling-stock and general engineering departments are expected to show improved returns, but owing to keen competition the margin of profit upon the manufacture of electrical machinery is small. The Brush Co. is largely interested in the tube railway authorised by Parliament to be constructed from the Marble Arch along the Edgware-road, but considerable uncertainty has prevailed in regard to the traffic question in London pending the issue of the report of the Royal Commission. In the meantime the construction has not been proceeded with. A further Bill will be promoted in the ensuing session, for which notice has been given, for an extension of time for construction, and also to authorise, as recommended by the Royal Commission, the construction of an underground railway from the Marble Arch to Victoria, forming an extension of the authorised Edgware-road tube railway.

NEW COMPANIES REGISTERED.

A T. Steel, Limited.—Capital, £10,000. Object: to carry on the business of electrical, automobile, and general engineers. Registered office: 27, Regent-street, Cheltenham.

British United Engineering Co., Limited.—Capital, £10,000. Object: to carry on the business of mechanical and electrical engineers, etc. Registered office: 175, Piccadilly, W.

National Radiator Co., Limited.—Capital, £50,000. Object: to carry on the business of manufacturers of radiators, boilers, and heating apparatus of all kinds, electrical and water supply engineers, etc.

Santa Rosa Rubber and Prospecting Syndicate, Limited.—Capital, £5 000. Object: to acquire any estates suitable for the production of rubber in Brazil or elsewhere. Registered office: 69, Moorgate street, E.C.

Traction Unification, Limited.—Capital, £10,000. Object: to undertake any business relating to the application of natural, animal, or mechanical power, or to traction, haulage, conveyance or other similar operations.

Liberian Rubber Corporation, Limited.—Capital, £270,000. Object: to adopt agreements with the Consolidated Rubber Syndicate, to acquire, cultivate and turn to account lands in the republic of Liberia or elsewhere, to plant, use, and grow rubber, etc.

British, Foreign, and Colonial Automatic Light Controlling Co, Limited.—Capital, £100,000. Object: to acquire patents, licenses, concessions; to carry on the business of mechanical electrical engineers, etc. Registered office: 55 Broad-street, Bristol.

London and General Power Supply Co., Limited.—Capital, £60,000. Object: to carry on the business of an electrical undertaking and in particular to provide, in the first instance, the financial necessities of the St. Neot's Electric Power Bill through Parliament.

Mundakayam Valley Rubber Co, Limited.—Capital, £15,000. Object: to acquire any lands, estates, buildings, factories, works, rights, and easements in Ceylon, India, the Straits Settlements, or elsewhere, and to carry on the business of cultivators of and dealers in indiarubber, etc.

Digitized by Google

Lens Lamp Co, Limited.—Capital, £60,000. Object: to take over the business carried on at 150, King's Cross-road, London, as the Bohm Lens Lamp Co.; to adopt an agreement with B.N.C. Limited, and to carry on the business of lamp manufacturers, glassblowers, electricians, etc. Registered office: 7, Great St. Helens, E.C.

Shanghai Electric Construction Co, Limited.—Capital, £320,000. Object: to enter into contracts with Messrs. Bruce Peebles and Co. and Dent Bros. and Co. relating to the acquisition by this company of the benefit of two contracts between the Council for the Foreign Community of Shanghai and Bruce Peebles and Co., relating to the construction and working of certain electric tramway lines in the foreign settlement of Shanghai, etc.

Liens Registered.

N.S. Electric Storage Co., Limited, Greenwich.—Lien registered Dec. 4 for £4,000 6 per cent. debentures. No trustees. Charged on the undertaking and all the property and assets, present and future.

Perth Electric Tramways, Limited, London, E.C.—Lien registered Dec. 6 for £600 6 per cent. debentures, part of £50,000. Amount previously issued, £39,000. Charged on the undertaking, property, and uncalled capital, subject to first debenture stock for £200,000.

Musselburgh and District Electric Light and Traction Co., Limited.—A trust deed dated Nov. 13, 1905, to secure £60,000 debentures, has been registered. Property charged: the company's undertaking and property, present and future, including uncalled capital. Trustees: Sir Nathaniel Nathan, Kt., The Cottage, Edenbridge; and M. R. Pryor, 48, Leadenhall-street, E.C.

PERSONAL.

Mr. J. C. Howell has been engaged as electrical adviser to Llanelly for a period of five years at a fixed salary.

The Nelson Town Council have appointed Mr. Murray Bolton Henry engineer and tramways manager at a salary of £200 per annum.

Mr. Henry Joseph, A.M.I.E.E., is leaving the Folkestone Electricity Supply Co., Hythe, in order to take up the post of engineer and manager to the Melton Mowbray Electric Light Co.

It is reported that Mr. Harry Richardson, the electrical engineer at Dundee, has been offered an appointment ranking high in his profession by one of the great electrical engineering firms in England.

Mr. D. F. Gorrie (son of D. Gorrie, Esq., head of the well-known firm of D. Gorrie and Sons, laundry and dyeworks engineers and coppersmiths, Perth) has been appointed chief draughtsman to the Industrial Engineering Co., Hyde, Manchester.

We learn that Mr. Bertram S. Giles, M.I.E.E., has been appointed by Messrs. Mather and Platt chief representative for London and the South of England for their electrical and hydraulic departments. Mr. Giles was previously employed for nearly 17 years by Messrs. Mather and Platt at their Salford Ironworks.

We are informed that Mr. John Cowan has resigned the managing directorship of the Stirling Boiler Co., of Motherwell and 25, Victoria-street, Westminster. The directors have appointed Mr. E. G. Constantine, A.M.I.C.E., M.I.Mech.E., of Manchester, to be managing director, and he will enter upon his duties at Motherwell on Jan. 1. Mr. Cowan still retains his interest in the company, and will continue to be chairman of the directors.

Mr. Gilbert C. Vyle, A.M.I.E.E., mechanical and electrical engineer, has resigned his post as works manager and assistant to the general manager of the telephone department of the General Electric Co.'s works at Salford, and has established himself at 14, Ridgefield, Manchester, as a consulting engineer for telephones and all systems of electric signalling. He is also specialising in works organisation and the manufacturing details necessary for the economic production of light and intricate mechanical and electrical apparatus.

Mr. Morton Beales was on Saturday evening, Dec. 2, most kindly entertained at a farewell dinner given by his friends at the British Westinghouse Co. upon his resigning his position of district office manager with that company in order to take up the position of manager to Messrs. Bruce Peebles and Co. Mr. Beales had been connected with the Westinghouse Co. for the last three years, and previous to that he was commercial engineer to Messrs. J. G. White and Co., having resigned his position with the Ferranti Co., on whose staff he had been for nearly 10 years. His address will be 1, London Wall-buildings, the new offices of Messrs. Bruce Peebles and Co.

On Saturday last the members of the Robertson private fire brigade held their second annual dinner at the Brook Green Hotel, when a very enjoyable evening was spent. Mr. Wilson (the works manager) was in the chair, and Mr. Driver (the assistant manager and superintendent of the fire brigade) occupied the vice-chair. After dinner the evening's entertainment took the form of a smoking concert, during which several toasts were proposed. Mr. Wilson said that the members of the fire brigade were recognised by the firm to be the most trusted of their employés. He thought that at this year's London private fire brigade competition they had missed carrying off the championship cup through their over-confidence, although they were to be congratulated on taking away one first and two second prizes. Mr. Rushworth, of Merryweather's (chairman of the London Private Fire Brigades' Association), replied on behalf of the visitors.

The annual staff dinner of the Portsmouth Corporation telephone department, which took place on Friday evening at the Clarence Hotel, Albert-road, proved a successful and enjoyable function. About 60 members and friends attended. Mr. C. M. Gardner (manager) presided, and apologised for the absence of Councillors W. T. Dittman, H. R. Pink, and J. Timpson, the consulting engineer (Mr. A. R. Bennett) and Mr. M. T. Maidment. "The Staff of the Portsmouth Corporation Telephone Department" was proposed by Mr. Harding and responded to by the chairman, who spoke highly of the individual and collective efforts of the officials connected with the undertaking. Mr. J. Teasdale, chief clerk, also replied, and said he believed the success of the undertaking was due in no small measure to the unflagging devotion and skill of the manager. He also referred to the admirable services rendered to the department by Messrs. W. J. Knox (outside superintendent), D. Macintosh (inside superintendent), T. H. Hillard (wayleave officer), and the Misses Paul and Bennett.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Swindon.—The Electricity and Tramways Department require tenders for three double-deck cars. Tenders by Dec. 19.

Heckmondwike.—The District Council are about to invite tenders for the installation of a plant for purifying the water for boiler purposes.

Grimsby.—The Corporation require tenders for contracts contained in Specifications No. 35 39 and 43-45, for electrical plant, cables, and buildings. Tenders by Jan. 5, 1906.

Madrid.—The Public Works Department require tenders for a concession to construct and work an electric tramway between Santander and Astillero. Guarantee, 8,195 pesetas. Tenders by Jan. 30, 1906.

Manchester.—Tenders are required for transformers and switchboards. Specifications may be obtained on payment of £1. 1s. (returnable) from the electricity department of the Corporation. Tenders by Dec. 19.

Launceston (Tasmania).—Tenders are invited for the supply of 500 or more electric meters and for maximum demand indicators. Tenders to Mr. C. W. Rocher, town clerk, Town Hall, Launceston, Tasmania, by 12 noon on Jan. 15.

Sofia (Bulgaria).—Tenders are invited for the electric lighting of the Government Cadet School. Tenders by Jan. 19. Offers must be addressed in the Bulgarian language and be accompanied by a deposit of 5 per cent. of the amount of the tender.

Derby.—The Tramways Committee invite tenders for the supply and delivery of materials and construction of works in connection with the conversion of existing single line into double line from Deadman's-lane to Navigation Bridge. Tenders to the Town Clerk by 9 a.m. on Dec. 19.

Spain.—The *Gaceta de Madrid* contains a notice inviting tenders, which will be opened at noon on Jan. 30 at the Directorate-General of Public Works, Madrid, for the concession of an electric tramway between Santander and Astillero. A deposit of about £208 is required to qualify any tender.

Brussels.—Tenders are required for the electric lighting of the marine hospital. Conditions may be obtained from the Secrétaire général de l'administration des hospices et secours de la ville de Bruxelles, Boulevard du Jardin botanique, hôpital St. Jean, Brussels. Tenders by Jan. 5, 1906.

Castlerea.—The Rural District Council invite tenders for the construction of works for lighting the town of Ballaghaderreen: (1) builders' work; (2) hydraulic turbine plant; (3) electrical work. Specifications and particulars may be had from Mr. C. Mulvany, M.I.C.E., Engineer's Office, Athlone, on payment of £1 as a deposit, returnable after receipt of bona fide tender. Tenders by Dec. 23.

Southport.—Tenders are to be obtained by the Town Council for the supply of a battery of accumulators and a booster to be worked in connection with the traction sets; a shaping machine is to be purchased for the workshop; and the electrical engineer has been instructed to rewind the field magnets of three alternators as soon as convenient, and to provide an atmospheric exhaust to the No. 3 traction set.

RESULTS OF TENDERS.

Burslem.—The tender of E. M. Evans and Co., at £104. 17s., has been accepted for fitting the St. John's Market for electric light.

Oulton Broad.—The Urban District Council have accepted the tender of the Oulton Broad Electricity Co., at £4. 2s., for installing the electric light in the Council room.

Tonbridge.—The Urban District Council have accepted the tender of the Rhodes Electrical Manufacturing Co., of 70, Bishopsgate-street Within, London, E.C., for the supply of motors.

Stafford.—The Town Council have accepted the tender of Baxendale and Co., Manchester, for the supply of wrought-iron tubes and fittings for the ensuing 12 months, for the Electricity Committee.

London County Council.—The tender of C. Wall Limited London, for erection of car-shed at Poplar required in connection with the electrical working of the first section of the northern tramways, at £29,006, has been recommended for acceptance.

Larne (Ireland).—The Urban District Council have accepted the tender of the Larne Electric Light Works, Suffolk House, Laurence Pountney-hill, Cannon-street, E.C., at £450, for the lighting of the public streets and roads of Larne for three years.

Birkenhead.—The tender of A. Reyrolle and Co. has been accepted for the supply and delivery of motor starters in accordance with the specification of Mr. Wm. Bates, A.M.I.C.E., borough electrical engineer, Birkenhead, during the period of 12 months commencing Jan. 1, 1906.

Pembroke.—The London Electric Firm, Croydon, have received an order from W. Lucy and Co., of Oxford, for 45 complete sets of their "one working part" arc lamp lowering gear for the street-lighting of Pembroke, in Ireland, the consulting engineers being Messrs. R. Hammond and Son.

Digitized by Google

Salford.—The tender of the Buxton Lime Firms Co. has been accepted for the supply of the limestone chippings required in connection with the laying of cables across the David Lewis recreation ground, delivered at the Ordsall-lane railway siding, at the following prices: 1½in. chippings at 4s. 7d. per ton, and ¼in. chippings at 6s. 6d. per ton.

Contracts Closed.—Portland Coaling Depot: the contract for conduits, feeder and arc lighting cables, underground boxes, and lamp pillars has been placed by H.M. Admiralty with Johnson and Phillips, of Old Charlton, Kent. **East Indian Railway Co.**: the company have accepted the tender of Johnson and Phillips for the supply of motors, transformers, and complete electrical plant for Lillooah.

A.B.P. Accumulators.—The A.B.P. Accumulator Co., Parkfield Works Stockton-on-Tees, have booked the following orders for their S type of cells: 480 cells, 13 plates, for Dumbarton; 25 5 ditto, Derby; 55 17 ditto, Oxford; 110 25 ditto, Croydon; and 54 9 ditto, Tain, N.B.; also 54 cells, 23 plate, OS type, Ealing; 54 sections, renewals, Newcastle; and 108 cells, 7-plate, L type, South Africa.

Clacton.—The Urban District Council have accepted the following tenders in connection with the electric power station: Davey, Paxman, and Co., horizontal two-cylinder engines with Parker dynamos, £3,676; Spagnoletti, switchboard, £600; Johnson and Phillips, cables, £4 098 11s. 9d.; D.P. Battery Co., accumulators, £1,450. The tender of Mr. J. McKay for buildings, at £2 743, subject to certain modifications being made in the specification, has also been accepted.

London County Council.—The following tenders have been received for supply of conductor tee rails, for the London County Council:—

Frodingham Iron and Steel Co., Frodingham, near Doncaster*	£8 250	0	0
Bolckow, Vaughan, and Co., Middlesbrough	8 550	0	0
P. and W. MacLellan, Glasgow	8,612	10	0
Steel, Peech, and Tozer, Sheffield	9,050	0	0

* Recommended for acceptance.

BUSINESS NOTES.

TRACTION.

Dundee.—The official inspection of the overhead equipment for the new tramways took place yesterday.

Salford.—A sub-committee will consider a readjustment of tramway fares between Salford and Pendleton.

Batley.—The local tradesmen are agitating in favour of continuing the running of cars from Birstall into Batley market on Saturday nights.

Liverpool.—At a meeting of the Council an amendment to the minutes of the Trams Committee for a reduced Sunday car service was rejected.

Leicester.—The annual supper and concert in connection with the Corporation Tramways Employés' Sick Benefit Society was held on the 12th inst.

Chesterfield.—The chairman of the Tramways Committee has informed the Council that the annual report of the committee will be presented in March.

Hythe.—By a large majority a town meeting has decided for a system of trams to be run through High street instead of another route that had been proposed.

Poole.—A large meeting of the ratepayers was recently held, when a protest was raised against the proposal to erect a bridge at Sandbanks in connection with a proposed light railway.

West Ham.—Notice was given of a resolution, to be moved at the meeting of the Council on Tuesday, that 30 of the Council's tramcars be fitted with covered tops as an experiment.

Edinburgh.—The Kingsland Electric Traction Co., we understand, are prepared to experimentally electrify the Mound route on the stud system, provided the sanction of the lessees is obtained.

Fareham.—Another trial run with the new cars was held last week and passed off very successfully. Though no date has yet been fixed for the formal opening, it is stated that it will take place before Christmas.

Islington.—The London County Council propose to proceed as rapidly as possible with the electrification of the tramways between Aldwych and the Angel, and the reconstruction of the Islington tramways.

Swindon.—It was announced at the meeting of the Town Council that the radial type of car had been adopted because it would carry 20 per cent. more passengers. The covering of the car-shed will cost about £300.

Bradford.—When an electric car was passing down Trunciffe, Wibsey, a man was crossing the road. He failed to get past before the car was upon him, and he was knocked down and received very serious injuries.

Northwich.—The Urban District Council have resolved to oppose the application of the promoters of the Warrington-Northwich Light Railway for an extension of time wherein to acquire lands for the construction of the railway.

Leigh.—The Council have appointed a sub committee to consider and report as to whether the tramways authorised by the Act, 1903, should be constructed with a view to their being worked by the Corporation or leased to a company.

Coventry.—A Board of Trade inquiry will be held respecting the complaints made by occupiers of premises in Smithford-street as to the tramway traffic through the street, and also concerning the proposed method of minimising the causes of complaint.

Bath.—The new Midland bridge was opened on Tuesday, the 12th inst., by Alderman Taylor, chairman of the Electric Traction Committee. The bridge is of fine proportions, and supersedes a smaller one. The electric tramway company contributed £11,000 towards the cost.

Dunfermline.—At a meeting of the Town Council a motion to take a *plébiscite* of the ratepayers to ascertain if they were in favour of municipalising the tramways, before the Council give consent to the Scottish Electric Traction Co. applying for a provisional order, was rejected.

Hastings.—A controversy is being carried on in the local Press relative to the merits of the overhead trolley and underground conduit systems of electric traction. It will be remembered that the tramways company are promoting a Bill which is for the erection of overhead equipment.

Paisley.—At a meeting of the Council on Wednesday it was resolved that the Council should appeal to the Board of Trade against the Paisley District Tramways Co. ceasing to run cars from the east to the west end of the town, and also having stages shorter than allowed by Act of Parliament.

Perth.—The Town Council have resolved to erect shelters at the tramway termini at Stone, Cherrybank, Craigie, and Dunkeld-road, some of the old horse cars to be converted for this purpose. The Town Council have adopted the Tramway Committee's recommendation for a reduction of children's fares.

Huddersfield.—At a specially convened meeting of the Town Council it was resolved to promote a Bill in Parliament to authorise the construction by the Corporation of further tramways in the borough, and to enable the Corporation to maintain and work such tramways as part of their tramway system.

Kingston-on-Thames.—The Town Council have postponed until Dec. 19 the consideration of the report of the Highways Committee in regard to the non-compliance of the London United Tramways Co. with the requirements of the committee, and of the question as to the institution of legal proceedings against the company.

Wigan.—In moving the confirmation of the minutes of the Electric Lighting and Tramways Committee at the last Council meeting, the chairman said the proprietors of the Horwich tramways had agreed to sell to the Corporation the stretch of line extending from the Wheat Sheaf in Standish to the Oak Tree in Coppull for £27,000.

Southport.—The Council have decided to discontinue the service of cars between Curzon-road and Ash-lane. There is now a 10 minutes' in lieu of a 12 minutes' service run on the inner circle route, and the following additional fares are now charged: between Blowick and Curzon-road, 2d.; between Curzon-road and St. Luke's-road, 1½d.

Burslem.—The tramways company have refused to accede to the request of the Corporation for the introduction of ½d. car stages. With regard to the proposed joint conference with Stoke with reference to complaints concerning cars, the Council have adjourned the conference in order to give the tramway company time to make the promised improvements.

East Ham.—At a meeting of the East Ham Council it was reported that the North Metropolitan Tramways Co. had intimated that they were prepared to accept £23,000 for their lines and depôt in Romford-road, East Ham, provided the Council undertake to complete the purchase before Jan. 31 next. It was decided that an offer of an amount be made to the tramway company.

Musselburgh.—Musselburgh and District Electric Tramways Co. have arranged a new set of fares for their system, which will take effect on and after New Year's Day. The all-the-way fare, 2d. for a three-mile run, will remain in force, but the intermediate stages, for which ½d., 1d., and 1½d. are charged, are lengthened, 1½-mile stages being given for 1d., and two-mile stages for 1½d.

Birkenhead.—It was stated at the last Council meeting that an accelerated traffic in the afternoon on the Oxton and Claughton Circle routes had been justified by the increased takings, but that there was no necessity for a faster service in the morning. The Mersey Railway Co.' motor 'bus service was inaugurated on the 11th inst. The four 'buses which are on the streets cost £900 each.

Darlington.—The Tramways Committee reported to the Council at their last meeting that the net loss on the year's working had been £1,400, or £27 per week, equal to a 2d. rate. This, however, did not include depreciation, which might be put down as something about 5 to 7½ per cent. This was under the ½d. fare system. Passengers had increased 20 per cent., but the receipts had only increased 1½ per cent.

Colchester.—The Tramways Committee have considered the manager's report as to the ticket system of collection of fares in lieu of boxes, and the introduction of intermediate stages, and resolved *nem. con.* to recommend that the ticket system be adopted, a sub-committee being appointed to fully consider the best means of working the system. The work of constructing the tramway along Military and Old Heath roads is proceeding satisfactorily.

Ayr.—The Town Council, at their meeting on the 11th inst., unanimously agreed to appoint a committee to report on the advisability of extending the tramway line to Hawkhill and Whitletts, also as to the necessary capital outlay, the working expenses, and the probable income from such extension. The Tramways Committee recommended the purchase of a tower wagon for the execution of repairs from Messrs. R. W. Blackwell and Co., at a cost of £65.

Metropolitan District Railway.—A further reduction of fares came into force on Monday last. Many of the "Cross-London" fares between that company's stations and the Metropolitan Co.'s Inner Circle stations has been reduced to 4d. first-class and 2d. third-class

Digitized by Google

for the single fare. Return fares are also greatly reduced. Similar reductions have also been made in fares between District Railway Inner Circle stations and Baker-street, Portland-road, Gower-street, etc.

Croydon.—At a meeting of the Town Council on Tuesday last it was unanimously decided not to accept the offer of about £4,000 a year in rent, upkeep charges, and share of the profits for a renewal of the tramway lease to the British Electric Traction Co. The company's lease expires next year. The question of municipalisation will be considered at a future meeting, but Alderman Stapleton, chairman of the Tramways Committee, said the committee regarded complete control by the Corporation as the only alternative to the company's offer.

Rochdale-Littleborough.—To celebrate the successful completion of the construction and reconstruction of tramways between these two towns, a dinner was held in Littleborough on the 6th inst., at the invitation of Mr. W. H. Ormerod, J.P. In reply to the toast of the undertaking, the Mayor said that on all the sections the total receipts up to date from March 31 were £27,445. 15s. 4d., giving a car mile of 9·30d. The total number of passengers carried during that period was 5,630,186, and the car miles run were 626,415.

Macclesfield.—A deputation from the East Cheshire Tramways Co. submitted to the Electricity Committee of the Council particulars of a scheme for a system of tramways in the town. It is proposed to construct the line from Hazel Grove to Macclesfield first and then to construct the Macclesfield line through a number of streets. The gauge will be the standard gauge of 4ft. 8½in. The route in the borough has been selected with a view to avoiding any street widening. As regards the supply of electricity, the promoters are willing to take it in bulk from the Corporation at a reasonable price. The promoters have not taken any powers in the draft Bill deposited by them to deal with the question of street widening. The scheme will be submitted later in writing. The motor 'bus scheme has been abandoned by the Corporation.

Aberdeen.—The number of passengers carried by the cars for the week ending the 2nd inst. was 283,155, an increase of 11,467, and 45 cars and 219 men were employed as against 39 and 207 respectively. The mileage rate over the system was 9·9d., the same as in the corresponding week of 1904, and the rate on the different routes was: Woodside, 10·4d.; Circular, 11·5d.; Mannofield, 11·7d.; Bridges, 8·5d.; Bayview, 10·0d.; Ferryhill, 7·9d.; Torry, 7·7d. The expenditure for the week on electricity and wages was £569. 1s. 2d., an increase of £28. 17s. 4d. The passenger fares for the 27 weeks of the financial year total £38,830. 12s. 7d., a decrease of £1,412. 4s. 2d, while the expenditure on electricity and wages for the same period amounts to £15,734. 5s. 4d., a reduction of £2,426. 5s. The Tramway Sub-Committee met again to define the duties of the tramways manager shortly to be appointed.

Bournemouth.—The Town Council have rejected a motion for running Sunday trams. It was recommended that the tender of Messrs. S. Brown and Sons for the erection of a tramway shelter and convenience, at £888, should be accepted. The Council approved of the instructions to the surveyor by the Tramways Committee, the surveyor to obtain specifications and estimates for two motorcars, and submit to the next meeting. The borough surveyor reported to the Tramways Committee that in order to put the existing track on the Poole Light Railway in proper condition it would be necessary to expend about £3,000, which sum would include new points and crossings. It was recommended that he be instructed to proceed with such works as were absolutely necessary to maintain the track in proper working order. The traffic manager also reported that in order to run the summer traffic satisfactorily on the Poole Light Railway between the County Gates and Poole it would be necessary to construct two new passing places and lengthen two existing passing places. It was recommended that the Poole Corporation be called upon to provide these additional passing places. The Council has agreed to these recommendations.

Newcastle.—A boy, in attempting to cross the roadway, was knocked down by a passing tramcar, despite the attempts of the motorman to pull up the car. Somehow or other the cowcatcher, it is stated, failed to act, and the vehicle passed over the little fellow's legs. The car had to be reversed before he could be extricated. An inquest was held recently into the death of an old man who was knocked down by a tramcar. A verdict of accidental death was returned, no fault being found with the driver, the coroner remarking that the men were very careful in their driving. They had a very difficult and arduous duty to perform, and they did it as well as could possibly be expected. A meeting of the representatives of the Tramway Workers' Union and the representatives of the Tramways Committee of Newcastle Corporation was held on Tuesday to consider the questions in dispute between the men and the Tramways Committee. After a long conversation the men agreed to withdraw their claim for extra payment for Sunday labour. On the other hand, the representatives of the Corporation agreed to withdraw their new regulation for the men to work 11 days per fortnight. The other questions relating to ordinary working hours were referred to arbitration.

Belfast.—The report of the Board of Trade representatives in regard to their recent inspection of the new tramways is, we understand, very satisfactory. In all, 31 miles of track have now been passed, and it is expected that the cars will be running over the remaining portion of the track in a few days. Horse traction has been finally brought to an end, and up to the present the new system has been working smoothly, there being no accidents, whilst slight defects in the controllers caused by damp are being remedied. On the first day of running 22,000 ½d. tickets for children were purchased. At a meeting of the Tramways and Electricity Committee of the Council on Monday, a number of suggestions were made to the general manager, Mr. Nance, all of which he has promised to consider carefully. With regard to the lighting of the tramway poles, the committee have requested the contractors to carry out the work. The committee decided that, with the approval of the Corporation, a bonus of £300 should be offered to Mr. Cutler and £200 each to Mr. M'Cowen and Mr. Nance. A further resolution was passed to the effect that Mr. Munce, assistant city surveyor, and Mr. Pinkerton, surveyor's department, should each get a bonus of £100, and that Mr. Lewis, who was clerk of works during the carrying out of the contract, should be given £20.

Hammersmith.—The Law and Parliamentary Committee of the Borough Council have had before them a letter from the Fulham Borough Council stating, with reference to the proposal of the London County Council to pave with granite setts the tramway track of the authorised tramways between Hammersmith and Fulham, that it has repeatedly urged upon the London County Council the desirability of substituting wood blocks between the lines, and suggesting that the Borough Council might communicate with the London County Council and request the Hammersmith representatives on that Council to support such proposal. The committee recommend that a further representation be made to the London County Council in opposition to the proposal to pave the tramway tracks with granite setts, and that, if possible, arrangements be made for a joint deputation from the two Councils concerned, to attend before the committee of the London County Council which is dealing with the matter. With reference to the suggestion of the Borough Council that the construction of the authorised tramway should be proceeded with with a view to providing work for the unemployed, the London County Council have replied that until the street widenings and bridge reconstruction works are completed it will be impossible to proceed with the construction of the tramways.

Great Yarmouth.—The Tramways Committee have reported to the Town Council that a copy of the Board of Trade regulations with respect to the use of the electrical power on the overhead trolley system has been received by them. The committee declined to accede to an application by the adjutant of the 2nd V.B. Norfolk Regiment for volunteers in uniform to travel at a reduced rate when going to and returning from parade at the drill hall and rifle range. After the fishing season, the terminus of Fish Wharf route will be at the barrack gates on Admiralty-road. The terminus of the Gorleston Quay route will be extended to a point opposite the lighthouse on the Gorleston Quay. Arrangements are to be made on two evenings in January, on the occasion of a dinner to the employés, for working the Yarmouth and Gorleston tramway services so as to admit of half of the employés being released from duty on each evening, and to allow collecting boxes to be placed in the cars for public subscriptions, no personal canvass by the men being sanctioned. A meeting of the Joint Tramways and Electric Lighting Committee resolved that the Electric Lighting Committee should return the equivalent of ½d. per unit for all electricity used for tramway purposes for the year ended Sept. 30, 1905, and for the year ending Sept. 30 1906, current for tramway purposes should be charged at 2½d. per unit. The Tramways and the Electric Lighting Committees agreed to this arrangement. This was agreed to by the Town Council.

Tramways in America.—A report by Mr. A. L. C. Fell, the chief officer of the London County Council tramways, on his visit to America to inspect the tramway system of the United States, was issued on Wednesday. He has tabulated the information received respecting the most interesting points in the more important of the cities visited, and has compared these with similar features of the County Council undertakings. The general impression gathered by Mr. Fell was that American engineers and their financial supporters are much more inclined to take the view that where there is a main road out of a city, or a possibility of connecting two cities, there should be a street tramway to develop the district. In many instances the undertakings do not prove a financial success for some years, but the country is being developed so rapidly that the risk is only a small one when the ultimate results are taken into consideration. The greatest incentive to the quick development of street railways in America is the fact that on the inter-urban lines the speed in the majority of cases is unlimited. Several times Mr. Fell travelled at the rate of 50 miles an hour with perfect safety on tracks laid at one side of the road. In most of the smaller cities the trackwork is of the cheapest possible character, and, apparently, that is all that is necessary until the undertaking is in a position to instal the work in a more permanent form. The condition of the paving in some of the cities which Mr. Fell visited is disgraceful, and would not be tolerated in this country. This fact, it is pointed out, should be taken into account when comparing the operating costs with those of similar schemes in London.

St. Neot's Power Scheme.—A syndicate has been formed to promote a Bill in Parliament to carry out an electric power scheme, generally known as the "St. Neot's" or "Railway" power scheme. A joint-stock company has been registered with a capital of £60,000 to provide, in the first instance, the financial necessities of the enterprise during the passage of the Bill through Parliament, and the names of the members of the syndicate which appear on the register as signatories to the memorandum of association are a guarantee that any necessary capital will be forthcoming for the ultimate construction of the electric works and mains. The directors of the syndicate are stated by the articles of association to be Mr. Stanley Boulter (chairman), Mr. George Kitchin, and Mr. H. A. Vernet. The objects of the Bill are the supply of electric energy in bulk to railways, metropolitan borough councils, and existing electric supply companies. The promoters are, we understand, directing their attention mainly to the supply of the great London railways, for the electrification of whose suburban traffic it is estimated that fully 700,000,000 units will in the near future be required; but negotiations are also pending for supplying in bulk municipal and other electric undertakers. The promises of support which the St. Neot's scheme has received from railway companies show that the latter are fully alive to the importance of having obtained such a strong group of capitalists who are ready to assist the railways by providing the money necessary

Digitized by Google

for a great electric power scheme which will obviate the necessity of the railway companies themselves adding to their own capital; while at the same time, by means of such a large installation and the other advantages already mentioned, a lower price per unit can be ensured than by independent organisations. It is expected that the direction of the St. Neot's Parliamentary Co., which will be formed after statutory powers are obtained, will largely consist of railway directors, who will thus keep closely in touch with traffic requirements.

London County Council.—At the meeting of the London County Council on Tuesday last, on the recommendation of the Parliamentary Committee to proceed with the Tramways Bill, Sir R. M. Beachcroft pointed out that the Bill contained proposals for the construction of new tramways in districts where the local authorities had refused to contribute one-third of the cost. In those circumstances, he asked if it was not waste of money to go forward with these proposals. Sir T. Brooke-Hitching said he believed the tramways did not pay, although he was unable to get the information he wanted from the Highways Committee. His opinion was that motor omnibuses had come to stay, and that the money they spent on tramways would result in a loss. Mr. Allen Baker, M.P., said the tramways of the Council on the south side of the Thames, notwithstanding many difficulties, showed a substantial profit. Colonel Colville said that the intention apparently was to join up the northern and southern systems by means of the Aldwych subway, but they would only be able to have single-deck cars through the tunnel. He felt that the motor omnibuses which could carry the passengers through Kingsway would kill the Council's trams, as in the case of the latter passengers would have to change from two-decker to one-decker cars. Mr. Waterlow denied that they would lose on this service. It was intended to use trailers through the subway, and thus enable them to cope with the traffic. It was agreed to proceed with the Bill. The Highways Committee recommended that the electrification of 22½ miles of tramway north of the Thames be proceeded with at a capital cost of about £800,000. The recommendations of the committee were adopted. It was proposed by the Highways Committee that the estimate of expenditure on capital account of £32,000, submitted by the Finance Committee, be approved in respect of the roadwork and platelaying (including rails) for the reconstruction of the existing tramways in Vauxhall Bridge-road, and the construction of tramways over the new Vauxhall Bridge, for the underground conduit system of electrical traction; that expenditure on capital account not exceeding £5,300 be sanctioned for the provision of track and slot rails, etc., for the reconstruction of the tramways in Vauxhall Bridge-road, and the construction of tramways over the new Vauxhall Bridge, for the underground conduit system of electrical traction; and that the offer of J. Mowlem and Co. to execute for the sum of £4 995 the roadwork and platelaying in connection with the construction of tramways over the new Vauxhall Bridge for the underground conduit system of electrical traction be accepted. With regard to the acquisition of a site at Holloway, the committee recommend (*a*) that the operation of the standing order relative to proposals involving expenditure on capital account of sums exceeding £5,000 be suspended in order that the subjoined recommendations may be considered; (*b*) that the estimate of expenditure on capital account of £21,000, submitted by the Finance Committee, be approved in respect of the acquisition of a site at Holloway for the erection of tramways buildings required for the electric working of portions of the Council's northern tramways; (*c*) that the freehold interest of the Tufnell and Caledonian Park Syndicate in the property in Pemberton-road and Pemberton-terrace, Holloway, known as the Caledonian football ground, be acquired for the sum of £20,000, subject to the condition that the main wall of the buildings on the northern boundary shall not be erected at less than 15ft. from the boundary wall in the rear of St. John's-park-mansions; that the valuer and the solicitor do complete the matter, allowing, in addition to the amount named, the necessary legal and other expenses; and that the seal of the Council be affixed to the agreement for the purchase. The committee also recommend that the conditions set out in the letter from the City Corporation indicating the terms upon which the Corporation would be prepared to promote a Bill in the parliamentary session of 1906 for the widening of Blackfriars Bridge and for the construction of tramways thereon, be accepted. The work of erecting a generating station at Greenwich is proceeding satisfactorily. It is hoped that the first portion of the station will be opened early next year. It will serve for the whole of the tramways south of the Thames which have been reconstructed for electrical traction, and also for the following further routes: the existing tramways from Wandsworth to Westminster Bridge and St. George's-circus, *via* York-road, Battersea Park-road, etc., including the lines in Falcon-road; the new tramways between Tooting and Wandsworth, *via* Garratt-lane, etc.; the extension of the existing electric tramways at Greenwich along Woolwich-road to Tunnel-avenue, and the new lines in Blackwall-lane; the tramways between New Cross-road and Catford, *via* Lewisham High-road, High-street, Lewisham, etc.

LIGHTING AND GENERAL.

Coventry.—No alteration is at present to be made in the present scale of charges for electric energy.

Burslem.—Sanction has been received to the borrowing of £5,500 for the extension of the electric lighting main to Tunstall.

Houghton-le-Spring.—The laying of cables for electric lighting in the Urban District Council's district is about to be commenced.

Taunton.—An inquiry has been held into an application of the Town Council for sanction to raise a loan of £4,844 for electric light purposes.

Rhymney.—The private syndicate formed for the purpose of lighting the Rhymney Valley with electricity will not proceed with their application for powers this session.

Dunoon (Argyleshire).—The Town Council are considering a proposal to build a refuse destructor and electric power plant at an approximate cost of £10,000.

Underground Telegraph Cable.—The underground telegraph cable has been brought from Manchester to Leeds, with the intention of ultimately carrying it to Newcastle.

Ascot.—The Ascot District Gas Co. are applying for a Bill to enable them to extend their limits of gas supply and to supply electricity throughout certain portions of their area.

Dundee.—The Town Council have decided in relation to applications for wayleave for poles by the National Telephone Co. to continue the existing arrangements—viz., a charge of 1s. per pole.

Chertsey.—The Rural District Council have received a letter from the Board of Trade relative to the Woking Electric Supply Co.'s order, and a further notice from Messrs. Foote and Milne.

Bradford-on-Avon.—The Rural District Council are consulting Mr. Geo. Pearson, of Bristol, with regard to the system adopted by the Somerset Electric Light Co. for the laying of cables and wires.

Cannock.—The minute of the Electric Lighting Committee which committed the Urban District Council to an experimental scheme to light the centre of Cannock at a cost of £3,000 has been approved.

Heckmondwike.—The Law and Parliamentary Committee have investigated the subject of meters at the power station, and are communicating with the Yorkshire (Woollen District) Electric Tramways Co. on the subject.

Australian Cables.—The Commonwealth House of Representatives, which has previously ratified the agreement with the Eastern Extension Telegraph Co., has now passed it with the amendment made by the Senate.

Tiverton.—The Town Council are presenting to the Local Government Board their objections to the Board's cancelling their electric light order, and also the grant of an order to the National Provincial Electricity Company.

Steel Chimneys.—We are informed that Messrs. Thomas Piggott and Co., makers of pipes, tanks, and steel structures, have just successfully completed two steel chimneys in South Wales, one 175ft. high and the other 125ft. high.

Epsom.—Six new applications, equal to 239 8-c.p., making a total of 9 184 8-c.p. for private lighting alone, have been received. During the last year the total number of 8-c.p. lamps increased from 7,085 to 9,154, an increase of 30 per cent.

Tredegar.—At the last meeting of the District Council a letter was read from the Board of Trade intimating that the electric lighting provisional order of the Council had been revoked, as the Council did not intend proceeding under the order.

Hartlepool.—The National Telephone Co. have obtained permission to place their wires underground in return for an annual payment of 13 guineas. The Northern Counties Electric Supply Co. are making some alterations in the street lamps.

Parton (Cumberland).—The Parish Council have appointed a committee to interview the Lowca Engineering Co., who are extending their electric plant, and have suggested that some arrangement might be made for the lighting of the village.

Brighouse.—It has been decided to at once provide three more telephone trunk wires between Brighouse and Huddersfield Post Office, thereby doubling the present service, and also provide two more wires between Brighouse and Huddersfield exchanges.

Hanley.—The Town Council have empowered the electrical engineer to purchase such short lengths of cable as may be required for extensions on the same terms and conditions as before upon satisfying himself that the rates are based upon the current market prices.

Broughty Ferry.—The estimate for lighting the parish church clock by electricity is much below that of gas, and the matter is under consideration. The current generated for November shows an increase of 2,712 units compared with the corresponding month of last year.

Liversedge.—The District Council have decided to withdraw the electricity supply scheme which had been previously adopted, estimated to involve an expenditure of £2,500. Application will be made to the Board of Trade for the period covered by the provisional order to be extended by 12 months.

Eastern Telegraph Co.—A dividend is announced at the rate of 3½ per cent. per annum, less income tax, on the preference stock for the quarter ended Dec. 31, 1905, and an interim dividend of 1½ per cent. on the ordinary stock, free of income tax, in respect of profits for the quarter ended Sept. 30.

Camberley.—An application from the York Town and Blackwater Gas Co. for consent to the company's application for a provisional order to supply electrical energy for private and public purposes, in accordance with Section 92 of the York Town and Blackwater Gas Act, 1904, is under consideration.

Newcastle.—At the last meeting of the Newcastle and Gateshead Chamber of Commerce it was stated that the chamber had agreed to write to the De Forest Wireless Telegraph Co. saying they would support any movement the company might have for placing a receiving stations at the mouth of the Tyne.

Warrington.—The following scale of charges for electric energy supplied for power has been adopted: load factor 40 per cent., charge 1d. per unit; 50 per cent., ·94d.; 60 per cent, ·88d.; 70 per cent., ·82d.; 80 per cent., ·76d.; 90 per cent., ·70d.—intermediate values of load factor being worked out proportionately.

Swansea.—The Electric Lighting Committee have received letters from consumers complaining of the high price of electrical supply. The Mayor, speaking at a meeting of the committee on Thursday, said electric light needed care in its use, but where the light was used night and day certain concessions would be made.

Digitized by Google

Fulham.—A conference of those borough councils who voted in favour of the proposal of the London County Council to introduce a Bill for enabling them to supply electricity in bulk is to be held at the town hall, Fulham, on Monday next at 3 p.m.

Buxton.—The Electricity Committee of the Urban District Council are favourable to the holding of an exhibition, provided a sufficient number of exhibitors can be obtained. Free current to be supplied, and skeleton stalls provided. Exhibitors are to do their own draping, and charges will be made for stall space and for advertising.

Electrical Exhibition.—The Charing Cross, West End, and City Electricity Supply Co. have organised an exhibition at 85 Fenchurch-street, E.C., which is to be of a permanent character, of the various machines, apparatus, and appliances by means of which electric power and energy have been made available for domestic and business purposes.

Larne.—The tender of the Larne Electric Lighting Works for public lighting has been accepted at £450 per annum. This includes the lighting of 14 arc lamps and 132 incandescent lamps from dusk to midnight, of nine arc lamps and 28 incandescent lamps from midnight to dawn; also to light throughout the months of May, June, and July.

Brighton.—A protracted inquiry has been held into the application of the Town Council for sanction to borrow £38,500 for electricity purposes and £5,909 for the purchase of the Star Foundry site, and for the erection thereon of buildings in connection with their electricity undertaking. The committee of ratepayers offered considerable opposition.

Electric and General Investment Co.—The directors have declared the following interim dividends: at the rate of 6 per cent. per annum on preference shares for the six months ending Dec. 31, being 3s. per share; and at the rate of 10 per cent. per annum on the capital paid up on the ordinary shares, being 1s. per share for the six months ended Nov. 30.

Glasgow.—The Electricity Committee recommend that application be made for further borrowing powers to the extent of £240,000 at least. It is proposed to put down three additional turbine generators of 4,500 h.p. each, as the tramways department will in course of time require all their current for tramway purposes, and will, therefore, not be able to supply supplementary current to the Electricity Committee.

Bermondsey.—Councillor Pridmore, in presenting the report of the Electric Lighting Committee at the last Council meeting, gave details which showed that the undertaking was making most satisfactory progress. Councillor Vezey stated that the undertaking was in a far better condition than when he undertook the chairmanship, nearly two years since. In every detail the works showed very satisfactory progress.

Boston (Lincs.).—The question whether the Corporation should seek to extend its order for electric lighting or allow a company to step in and do the work came before the last Town Council meeting, and it was decided that the Paving and Lighting Committee should endeavour to make the best terms possible with any company that may seek to obtain a provisional order for the supply of electricity within the borough.

Hampstead.—The Council recently revised the charges for current for lighting, and at the last meeting decided to reduce the price for electric current for power from 2d. per unit to 1d. per unit, with a minimum charge of £1 per quarter per kilowatt installed, or, at the option of the consumer, to 1½d. per unit without a minimum charge. It was also decided to reduce the charge for current for heating from 2d. to 1½d. per unit.

Inquest.—An inquest was held at Consett last week regarding the death of T. H. Thomas, aged 40, who was apparently killed by an electric shock in the blacksmith shop of the Pelton Fell Colliery on the 28th ult. The expert evidence seemed to show that 254 volts would be the highest voltage to which the deceased was subjected when handling a fusible lamp. The inquest was adjourned to allow a post-mortem to be made.

Cromer.—The annual report of the engineer on the electric light undertaking to June 30 shows that the estimated capital expenditure during the next two or three years, with a provision of £3,580 for house services, etc., will amount to £11,000. Application will probably be made for sanction to a further loan of £11 000 in connection with the electric light undertaking. Inquiries are to be made with reference to the special charges now being made by the contractors to consumers.

Yarmouth.—The Council have approved of the principle of establishing a showroom and office in a central position in the town for the purpose of displaying electrical appliances for heating and lighting. The same would also be used as an inquiry office. The resident engineer reports that during the month two new consumers have been connected to the mains, representing 252 8-c.p. lamps. There are now connected to the mains 660 consumers, representing 32,668 8-c.p. lamps.

Gomersal.—At their last meeting the District Council received a letter asking for consent to a provisional order which is being promoted by a private company for the distribution of electricity in Gomersal. The company stated that they would fix the maximum price at 6d. instead of the usual 8d., and if they obtained the order with the Council's support they would pay the Council's reasonable costs, and provide a supply in Gomersal at the earliest date. Nothing was done in the matter.

Longton.—The number of units generated for the six weeks ended Nov. 23 was 11,849 against 9,929 for the corresponding period of last year, being an increase of 19 per cent. An expert is to be engaged to value the gas and electricity works for poor-law assessment purposes. The chairman, vice-chairman, Councillors Brewer, Brookhouse, Derbyshire, and Taylor have been appointed a sub-committee to consider the question of electricity extensions and charges for current both for lighting and motive power purposes.

Southport.—A sub committee has been empowered to settle the price at which electricity can be supplied for the purpose of working the pumps at the new sewage disposal works. The plan of the electrical engineer for the erection of the necessary buildings to contain a new battery of accumulators has been adopted. The Tramway Committee have agreed to provide for trial purposes a new wattmeter to be used in conjunction with the present traction meters.

Hammersmith.—Sixteen additional consumers, representing a maximum of 1,761 8 c.p. lamps, have been connected to the mains, and six consumers have been disconnected, the present number of consumers taking current from the mains being 1,746. The Council are buying from the Bat Electric Co. 50 10-ampere meters which were hired from them for the purpose of the exhibition at Olympia in October last, at £1. 17s. per meter, the company foregoing the fee of 5s. each for the hire of the meters during the exhibition.

West Bromwich.—The dispute between the Corporation and the tramway company has been settled. At the last Town Council meeting a view was expressed that under the revised agreement the Corporation would stand the risk of losing £624 a year, the cost of 100,000 units of electricity which the company would not require. In the year ending Sept. 30 the tramway company had taken 1,039,536 units at £7,330. It was feared that if the company were using smaller cars, and were running those at less frequent intervals, their current bill would be reduced.

Basford (Notts).—At the last meeting of the Guardians the question of economy and improvement in the lighting of the workhouse was discussed on the presentation of a report from the Visiting Committee recommending the installation of electric light on the premises, and the provision of the necessary power for producing the same in the most economical manner. The estimated cost was mentioned as £2 000, and the committee suggested that Mr. Betts, architect, should be instructed to prepare plans. The report will be considered at the next meeting.

Sunderland.—The Town Council have decided to borrow £18,000 for extensions to the electricity station. Mr. Alderman Bruce, chairman of the Electricity Committee, stated at the last meeting that they had been very successful, and at the end of the current year they would have a net profit of £3,000. The demand had increased enormously, owing to engine works and shipyards taking current for motive power. Amongst others, one firm had stated that the cost of electricity had been £300 per annum less than steam, and several others had found a great financial gain.

Gillingham.—We understand that the Council have decided to extend their agreement with the Kent Electric Power Co. to Aug. 31, 1906. The price charged for current is to remain as at present—viz., 2 5d. per unit—the company being able to work up to a maximum load of 450 kw. The engineer has reported a total of 47,663 8 c.p. lamps with 265 consumers connected, and that applications had been received for the equivalent of 268 8-c.p. lamps. Several new public lighting mains are to be laid. The agreement with Chatham has been referred to the Council in committee.

Salford.—The electrical engineer is preparing details of his proposals for increasing the plant at the electricity works in order to meet present and future demands for electric current. Five additional reverse-current circuit breakers are to be purchased from Cowans Limited at the price of £8 each. Additional cables will be laid in the Eccles New-road area for improving the pressure of current supplied to consumers in that district at an estimated cost of £2,112 15s. A recommendation by the electrical engineer to add additional switches to the lighting and power switchboard at a cost of £170 has been approved.

Edinburgh.—The report of Mr. John F. Simmance, A.M.I.C.E., M.I.M.E., on the gas and electric lighting of Edinburgh states that the former was supplied at over 24 candles, the average variations being a minimum of 2ft. and a maximum of 4¼ft. He considers that the electric current is eminently satisfactory in the centre of the city, but shows great variation in the Portobello district. He expresses disapproval of the incandescent gas lighting. Of the gas expended in the lamps, at least 40 per cent. was wasted. For the want of a small additional sum for mantles and maintenance, 40 per cent. of the cost was thrown away.

New Issue.—The British, Foreign, and Colonial Automatic Light Controlling Co. Capital, £100,000. Object: to acquire as a going concern the goodwill of the business of the business of the Automatic Light Controlling Co. and the patents and rights of Mr. John Gunning's inventions for lighting and extinguishing all descriptions of gas lamps at a predetermined time or predetermined times, and for improvements in apparatus for opening and closing electric circuits at predetermined times. The object of the mechanism, the subject of the inventions to be acquired by the company, is the automatic lighting and extinguishing of public, private, or other lamps, whether their light be derived from gas, electricity, or other illuminant.

Fraserburgh.—At the last Council meeting Mr. Alexander submitted the following summarised report as to the electric lighting of the town from the tool works: "The Council pay to the company the sum of £4,000 to meet the cost of constructing additional plant required, and the company to supply the town with the electrical energy at 2d. per unit for the first two years and at 1½d. thereafter. The cost of constructing the necessary underground cables would be £4,000, so that the Council would have a capital expenditure of £8,000, and the area to be treated embraces 81 street lamps, for which they at present pay £67. 10s. per annum." The matter has been deferred for further consideration.

Dunfermline.—Further correspondence ha taken place between Provost Macbeth, Dunfermline, and the Fife Electric Power Co., and

Digitized by Google

also with the National Gas Co. and Tangyes Limited, regarding the question of supplying electricity to the Corporation. The Fife Electric Power Co. have now offered the following terms under a 10 years' agreement: under 100 000 units, 1⅜d. per unit; 100,000 to 200 000, 1¼d.; 200 000 to 300 000, 1⅛d.; 300,000 to 500,000, 1d.; 500,000 to 750,000, ⅞d.; 750 000 to 1,000,000, ¾d. The National Gas Co. estimate that the price would be as follows: 127 500 units, 1·7d. per unit; 200,000, ·947d.; 750 000, ·624d.; 1,000,000, ·504d. No allowance is made in either estimate for the cost of distribution.

London Gazette.—The Otto Electrical Manufacturing Co. (1905) has been wound up voluntarily, and Mr. E. H. Fletcher, 14, George-street, Mansion House, London, appointed liquidator. The Imperial Electric Lamp and Battery Syndicate has been wound up voluntarily, and Mr. A. Stevens, 105, Gresham House, Old Broad street, London, appointed liquidator. The first meeting in the estate of J. W. Smith, electrical engineer and contractor, 55, Bolton-road, Darwen, will be held at the Official Receiver's offices, 14, Chapel-street, Preston, at 10.30 a.m. on Dec. 18. A receiving order has been made out on creditors' petition in the estate of W. Leslie, electrical engineer, lately carrying on business at 22, Bangalore-road, Putney.

Battersea.—The proposed new charges for meter rents are as follows: If any consumer's quarterly account amounts to less than 12s., a meter rent of 3s be charged. Should a consumer's account exceed 12s. but be less than 15s. during any quarter, such sum shall be charged for meter rent as will bring the total up to 15s. No meter rent to be charged to consumers whose quarterly account exceed 15s. If more than one meter is fixed on a consumer's premises, the above conditions shall apply separately in respect of each meter. The net amount to be paid by the County of London Electric Supply Co. relative to the supply of electrical energy in areas transferred under the provisions of the London Electric Lighting Areas Act, 1904, is £595. 5s. 4d.

Islington.—At the last meeting of the Borough Council, in reply to a question as to the charge upon the rates for each arc lamp for the half-year ending March 31, 1903, and the half-year ending March, 1905, the borough treasurer said for the former half-year it was £32. 15s. 9d., for the latter half-year £37. 12s 11d. At to-night's meeting the Finance Committee will submit a report in regard to the proposed extension of arc lighting in the streets of the borough at a cost of £21,011, expressing the opinion that, having regard to the uncertainty which at present surrounds electrical undertakings in London, and to various circumstances affecting the Islington undertaking in particular, the Council should not sanction the further large capital expenditure now proposed by the Lighting Committee.

Hastings.—The income of the electricity works for the year ended Dec. 31, 1904, was £19 467. 18s 5d., and the expenditure £19 351. 5s. 10d., leaving a net profit of £116. 12s. 7d. The accumulated deficiency brought forward from the previous year was £4 468. 8s. 11d. This was reduced during the year by the sum of £1,125, raised by means of a general district rate, and the net profit referred to of £116. 12s. 7d., leaving a deficiency carried forward at Dec. 31, 1904, of £3,226. 16s. 4d. This account shows a marked improvement over the previous year, when the net deficiency was £951. The interest and sinking fund charges absorbed 48·24 per cent. of the total income. The capital expenditure during the year amounted to £4 987. 10s. 2d., bringing the total at Dec. 31, 1904, up to £136 819. 9s. 5d.

Southwick.—The Urban District Council have decided to enter into a contract with the County of Durham Electrical Power Distribution Co. for the lighting of certain streets. The contract is to commence at the expiration of the present contract with the Sunderland Gas Co. in July next. The terms of the contract with the Distribution Co. has been left in the hands of a committee, on the understanding that the initial cost of providing the necessary plant be spread over a period of five years. It appears that the company will charge £280 for putting up the lamps and providing all the material for the lighting of the roads. They are willing to accept payment of this initial cost by yearly instalments covering a period of five years. After deducting the value of the old lamps, the net annual charge comes to £141. 16s., against £145. 7s. for the annual cost of lighting the same roads by gas.

Ayr.—The Ayr Harbour Trustees have of late had under consideration a proposal to generate current for the electric lighting at the harbour, and have obtained a report on the subject from a consulting engineer, who has also dealt with the probable cost of supplying current for the new lamps, the Trustees propose to erect on the south side of the harbour and certain additional lamps for the north side and wet dock. The recent charge made by the Ayr Corporation is £21 per lamp, and about 17 additional lamps are required, the additional lamps and cables being provided by and remaining the property of the Trust. The Town Council have offered to supply current to the Harbour Trustees at the rate of £18. 10s. per lamp, on condition that no fewer than 31 lamps are erected; and that on the same terms and conditions now applicable to the existing lamps. This charge to come into operation so soon as the whole lamps are in use.

Cardiff.—Western Mail-chambers have become a centre for electrical, machinery, and allied firms. This is, the *Western Mail* says, no doubt, due to the central position of the chambers, which are situated in St. Mary-street, close to the Great Western Railway Station. The firms which have offices in the Western Mail chambers include: Clay Bros. and Co., electrical engineers; Electrical Co., lighting and machinery; Callender's Cable and Construction Co.; Crompton and Co., electrical engineers; British Insulated and Helsby Cables; Sinnot and Stracey, civil engineers; H. T. Wales, mining and civil engineer; Vacuum Oil Co.; Uskside Engineering and Rivet Co., colliery engineers; Plowright Bros., colliery screening plant; Ospell Fan Co., colliery fan manufacturers; Simon Carves Limited, coke ovens and coke-washing plant; Penman and Co., boilermakers; Last, Son, and Co., metal brokers; Frank B. Last, analytical, metallurgical, and consulting chemist; G. Hamilton and Co., machinery auctioneers.

Tonbridge.—It has been decided to adopt from March 31 next reduced charges for street-lighting by electric lamps as follows: Each arc lamp £20 per annum for the year ending March 31, 1907, to be further reduced to £18 for the year ending March 31, 1908. This will effect a reduction for the first year of £90 and for the second £126 in the charge for arc lighting. The charge for all electric lamps to be reduced from £3. 15s. per half-ampere Nernst lamp to £3. 12s. 6d. per annum, equivalent to a total reduction of £7. 5s. on the existing 58 lamps, with a further reduction to £3. 10s. per annum after March 31, 1907, in the case of all converted gas columns. This offer has been made on condition that all gas lamps on the line of electric cable shall be replaced with electric Nernst lamps, subject to the gas company's minimum of 200 lamps being maintained. Arrangements are to be made for a suitable man periodically to inspect consumers' installations, with a view to advising them with regard to the lighting and lamps generally. The engineer reported that this can be done without loss (and probably at some profit) to the Council.

Morley.—The borough electrical engineer (Mr. J. E. Ellis) in his last report states that the output from the electricity works for the month ending Oct. 31 was 17,030 units, as compared with 16,504 the same month last year, showing an increase of 526 units. The actual units sold to consumers by meter was 11 894, against 10,258 the corresponding month of last year, being an increase of 1,636 units. Thirty lamps had been connected during the month, the lamps connected to date numbering 13,154, and the motors now connected equalled 27½ h.p. The following have been appointed the committee to examine the accounts prior to the monthly meetings: the chairman, vice-chairman, Alderman J. H. Smith, and Councillor G. E Baines. The consideration of the question of the provision of tanks and apparatus for feeding the boilers with the waste water has been deferred until the next meeting. The borough electrical engineer is about to arrange for an exhibition of electrical appliances to be held in the King's Hall during May, the committee to provide the current for the exhibits free of charge, but to incur no further responsibility.

West Ham.—In a recent report the electrical engineer points out, with reference to the agreement entered into with Jeyes' Sanitary Compounds Co. for a supply of current for power purposes on the Hopkinson system—viz., £1 per kilowatt demanded, plus ·7d. per unit for all current consumed—that he finds that in this particular case the system of charging for the quarter ended September last worked out very much against the consumer, the average price being 8½d. This was due to the fact that their machines had only been running experimentally, instead of being engaged on regular work. The company is to be allowed a flat rate of 1⅜d. per unit until such time as their machines are working at their normal load. The engineer also recommends, with reference to the hire of motors, that the consumer's rental be 15 per cent. per annum on the cost of the motor supplied, which covers the Corporation for capital charges, depreciation, repairs, and maintenance; and that as by this payment the consumer has covered these costs on the motor, he be charged by the ordinary rate in force for the supply of current for power.

Hounslow.—An inquiry has been held into the application by the District Council for sanction to a loan of £11,500 for the purposes of extensions of the electric lighting system. Mr. H. J. Baker (clerk to the Council), Mr. J. Enright (the Council's consulting expert), Mr. Bond (the electrical engineer), and Mr. W. J. Lobjoit (chairman of the Electric Lighting Committee) attended. The application included £1,262, the amount spent in excess of the loan of £35,000 sanctioned in June, 1903, and £10,238 mainly in connection with additional mains. Mr. Baker explained that the great bulk of the excess in expenditure was due to the need for two more boilers, the wisdom of which had been shown by the way they had helped to overcome breakdowns on the part of the original boilers. The actual outlay to be made on mains was £7,434. At the time of the first inquiry held in connection with electric light, it was estimated that in the first year there would be consumption equal to 9,000 c.p., but the actual to the end of the first year was 14,272, which showed that the forecast of the Council was more than justified. They believed, therefore, they were justified in making extensions, particularly as the district north of Hounslow was increasing. Eight hundred and eighty-four pounds was charged for lamps, of which 25 would be arc standards, and the rest incandescent globes fitted to existing gas standards. Other expenses would be spread over extra dynamos, and the construction of a 27ft. deep well and storage tanks raised on columns high enough to distribute all over the works. It was known that a good supply of water could be obtained, and the Council, by sinking the well, believed they would eventually save a great deal of money. With reference to revenue coming in, the Council was doing very well. In November, 1904, when the concern was opened, there were 3,952 equivalent 8-c.p. connections of all kinds. In November last there were 13 628, and to the present day there were applications for connections amounting to 14,272. The charge per unit was 5d., subject to discounts, and 3d. per unit where supplied in bulk.

Portslade.—Portslade, Southwick, and Shoreham are making combined endeavours to obtain provisional orders retaining in their own hands the power to supply the district with electricity. The Chairman, at the last meeting of the Portslade Urban District Council, said that the joint committee had met the Brighton Committee recently. It had previously been decided, subject to the approval of their several Councils, that they should apply for the provisional orders, that they should borrow the money, and that the Brighton Corporation should be asked to supply the electricity at a price to be agreed. The Corporation were also to be asked to lay the cables, and it was also understood that Brighton were to have a lease of the three orders, paying as rent the whole of the loan, the whole of the sinking charges, and the cost of the provisional orders, so that not a penny of the whole expense came upon their rates. No objection was

Digitized by Google

offered, and they got as far that, and thought a month or two ago they were going to get the provisional order this next session. Owing to the fact, however, that the Board of Trade said it was necessary to insert in the order the name of the company which would supply the electricity, if they were not going to supply themselves, they had to abandon their intention of applying for the order until next year, as they had not concluded terms with Brighton, the price not having yet been settled. Brighton had offered them something, but it was not just what they wanted. But there was now another difficulty. The town clerk was advised by his parliamentary agents that they could not apply for provisional orders and let Brighton supply them with electricity, but that Brighton must apply with their consent. Their (the joint committee's) parliamentary agent, however, advised just the contrary, and that they could obtain the provisional orders. The matters were gone into at the meeting with Brighton, and it was concluded with this difference between them and the question of price, which they wanted to get as near the Brighton price as possible. He thought they were all agreed they should protest against Brighton taking the provisional order unless it was forced upon them.

Derby.—The electric light mains are to be extended from the works of Messrs. Handyside and Co. to Messrs. Holme and Co.'s mill in Bath street. In answer to a question by Mr. Clifford Newbold with reference to engines that had been pulled out of the electric lighting station up to March last, Mr. Alderman Butterworth replied, at the last Council meeting, that altogether up to the present time eight plants had been removed from the use for which they were installed. There were first three sets of 50 h.p. each. The original value it was impossible for the committee to say. The fact was that the whole of the bills relating to the establishment of the electric light works were not in the hands of the Corporation, but in the hands of the engineers and advisers for the works. Some years ago he remembered that a former committee made application to have these bills. An application was made to the firm of engineers for the bills to be placed at the disposal of the Corporation, but the Corporation were only offered the privilege of inspecting the bills at the firm's offices. That was not accepted, and he supposed the engineers were within their rights in retaining the papers, seeing they formed one of the bases on which the engineers issued their original certificate. So he could not give the exact value. The committee estimated the value of the three sets he had mentioned at £1,200. Then there were removed two sets of 100 h.p., approximate value £1,200, and there had also been three sets of 40 h.p. each, and their original value would be somewhere about the same amount—viz., £1,200. The total cost of the eight plants was estimated at £3,600, and this worked out at nearly £10 per horse-power. The operation of the sinking fund had written off about half this amount, leaving to be accounted for the sum of about £1,800. Parts of these plants had been sold at various times for £265. Two plants had been taken by a firm who supplied the committee with transformers, they in exchange giving transformers to the value of £320. The committee considered it an excellent exchange, and this was reported to the Council at the time the transaction took place. The committee had already given instructions for £650 to be taken from the reserve fund to wipe off the debt on three plants for which the committee had no further use. The last three sets were removed during March to make room for works carried out at the present time. The figures he had given left the sum of £565 not yet written off but represented by engines in the stores which it was intended to sell as opportunity arose, and whatever loss occurred on the transaction would be written off out of revenue. But if mention was made of a small portion of machinery moved from a large concern like this, he had a right to go further and speak of other portions of machinery and appliances which had been renewed, brought up to date, and paid for out of revenue. The whole of the street arc lamps, 78 in number, had been replaced and brought up to a higher efficiency than they were originally out of revenue account, over £1,200 having been spent in recent years. After the old lamps had been used for nine years they were replaced by lamps of greater efficiency, and it would lengthen the life of that particular part of the machinery by 10 or 11 years. Then, again, there was another matter in connection with the change over to direct current made in the centre of the town. During the last two years over £2,000 had been spent out of the revenue account in modernising the system of mains, and as a result there was now a more efficient system of mains than 10 years ago. The foundation beds on which the old plants were fixed had been utilised in carrying the steam-turbines and other extension plant, and any necessary alteration of these had been done out of revenue. The total cost of service connections for the year ending March last was between £400 and £500. This was a perfectly legitimate capital expenditure, and sums for this purpose were applied for and granted by the Local Government Board each year. A short time ago he had occasion to allude to the shortness of memory of some members of the Council. In April last Mr. Newbold, by his presence, assisted to pass a resolution by which the committee were empowered to ask the Local Government Board for £600 for this very purpose. It was an annual expense which had never yet been refused by the Local Government Board.

London County Council.—On Tuesday it was agreed to lend the Hackney Borough Council £1,200 and the Stoke Newington Borough Council £16,925 for electric light installations. A report on the proposed Bill giving powers to the Council to supply electricity in bulk was submitted by the Highways and Parliamentary Committees. The total capital powers sought by the Bill, with which we deal in another column, amount to about £2,500,000. Next week the Highways Committee will recommend that they be authorised to take any necessary preliminary steps, including the invitation of tenders, for the execution of the several works necessary for the erection and equipment of the second portion of the Greenwich electricity generating station and sub station. The recommendations are as follows: (*a*) that the estimate of expenditure on capital account of £186,000, submitted by the Finance Committee, to cover the cost of the erection of the second portion of the Greenwich electricity generating station and the Greenwich sub-station, be approved; (*b*) that the estimate of expenditure on capital account of £250,500, submitted by the Finance Committee, in respect of the provision of the plant, machinery, and other equipment for the second portion of the Greenwich electricity generating station and the sub-station in connection therewith be approved; (*c*) that the capital estimates of £2,000, £15 000. £18 500, £1,500, and £30,000, approved by the Council on Oct. 13, 1903, July 26, 1904, March 14 1905, and Arg. 1, 1905, in respect of preliminary works and expenditure in connection with the erection and equipment of the second portion of the Greenwich electricity generating station and the Greenwich sub-station, be cancelled; (*d*) that the Highways Committee be authorised to take any necessary preliminary steps, including the invitation of tenders, for the execution of the several works necessary for the erection and equipment of the second portion of the Greenwich electricity generating station and sub-station. The Council on May 26 and June 23, 1903, decided to require the Kensington and Knightsbridge and the Brompton and Kensington Electric Lighting Companies to provide and maintain stations, in accordance with the provisions of the companies' orders, for the testing by the Council's inspectors of the electrical energy supplied to consumers by the companies within their areas of supply. Similar provisions relative to the establishment of testing stations are contained in other orders, but in most cases the Council has not been in a position up to the present time to call upon the undertakers to fulfil their obligations as regards the provision of testing stations. We have since been in negotiation with the County of London Electric Supply Co. with a view to the establishment of such stations in its areas of supply south of the Thames. No definite decision has yet been arrived at by the company upon the matter, and in the meantime we think that the company should be formally required by the Council to provide testing stations. It is proposed that a notice be served upon the County of London Electric Supply Co. requiring them, in accordance with the provisions of the Wandsworth, Southwark, St. Olave, and Camberwell Electric Lighting Orders, 1892, 1892, 1895, and 1896 respectively, as confirmed by the Electric Lighting Orders Confirmation Acts of 1892 and 1896, (*a*) to provide and maintain testing stations with proper and suitable instruments of a pattern to be approved by the Board of Trade; (*b*) to connect such stations, by means of proper and sufficient electric lines, with the company's distributing mains; and (*c*) to supply energy thereto for the purpose of testing. Notices under Electric Lighting Acts and orders have been agreed to as follows: City of London Electric Lighting Co., of intention to lay mains along a portion of Gravel-lane; County of London Electric Supply Co., to lay high and low tension mains along Collier-street and along Claremont square and Amwell-street; Metropolitan Electric Supply Co., under the Mid-London Order, 1889, to lay mains along portions of the Strand and Aldwych and along Castle-street; South Metropolitan Electric Light and Power Co., to lay low tension mains along and across Shooter's Hill-road and across a portion of Blackheath, and along portions of St. Mark's-road and Gilmore-road, and across High street, Lewisham, and along portions of Court Hill-road, Hither Green-lane, and Ladywell Park-terrace; Westminster Electric Supply Corporation, to lay mains along Laundry-yard and a portion of Horseferry-road.

PROVISIONAL PATENTS, 1905.

DEC. 4.

25084. Improved sand gear for electric tramcars and the like. Harry Lawrence Kenworthy, 42, Forest-road, Lower Edmonton, London.

25085. Safety electric car step. Henry Fielding, 153, Dantor-road, Hooley Hill, near Manchester.

25114. Electric lock. Tom Hildred Scrimshaw, 94, Meadow-lane, Leeds.

25131. Improvements in switchboards. Claude Kennedy Mills, 23, Southampton-buildings, Chancery-lane, London. (Marie Vitous and William Pierson Hammond, United States.) (Complete specification.)

25147. Improvements in connection with the regulation of alternating-current motors. Elektrizitäts Aktien-Gesellschaft vorm. W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Dec. 2, 1904, being date of application in Germany.) (Complete specification.)

25153. Improvements in appliances for protecting electric apparatus against currents of excessive strength or voltage. Soc. Industrielle des Téléphones, Constructions Electriques, Caoutchouc Cables, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 13, 1904, being date of application in France.) (Complete specification.)

25169. Improved means for operating the controlling switch of electric vehicles. Louis Krieger and Cie. Parisienne des Voitures Electriques (Procédés Krieger), 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, March 9 1905, being date of application in France.) (Complete specification.)

25171. Improved means for controlling an electric motor. Louis Kriéger, 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 24, 1905, being date of application in France.) (Complete specification.)

Digitized by Google

25172. **Improvements in or relating to electrically-propelled vehicles.** Louis Kriéger and Compagnie Parisienne des Voitures Electriques (Procédés Kriéger), 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 24, 1905, being date of application in France.) (Complete specification.)

25173. **Improvements in electrically-propelled vehicles.** Louis Kriéger and Compagnie Parisienne des Voitures Electriques (Procédés Kriéger), 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 30, 1905, being date of application in France.) (Complete specification.)

25174. **Improvements in electric furnaces.** Soc. Anon. Electro-metallurgique (Procédés Paul Girod), 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Jan. 4, 1905 being date of application in France.) Complete specification.)

DEC. 5.

25224. **Improvements in cases for electrical measuring instruments.** Edgar Isaac Everett and Kenelm Edgcumbe, Collindale Works, Hendon, London.

25236. **Improvements in and relating to Nernst lamps.** Allgemeine Elektricitäts Ges., 27, Chancery-lane, London. (Date applied for under Patents Act 1901, Dec. 5, 1904, being date of application in Germany.) (Complete specification.)

25257. **Improvements in or relating to arc lamps.** Frantisek Jarecek, 111, Hatton garden, London. (Complete specification.)

25283. **Improvements in electromagnetic band brakes for vehicles.** Henri Dolter and Gustav Mertens 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 5, 1904, being date of application in Germany.) (Complete specification.)

25287. **Method of and apparatus for striking electric arcs between electrodes.** Albert Johan Petersson, 322, High Holborn, London. (Complete specification.)

25288. **Improvements in electric signalling apparatus.** Alfred Francis Street, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

25295. **Coin-actuated electrical advertising device.** Howard William Chinnery, George William Chinnery, and Florence Chinnery, 97, South-avenue, Southend, Essex.

DEC. 6.

25347. **Improvements in electric cut-outs.** John Henry Christopher Brooking and Ernest Alexander Claremont, 4, Bloomsbury-square, London. (Complete specification.)

25353. **Improvements in apparatus or devices for generating electricity on motorcars or motorboats.** Joseph Taylor, 33, Chancery-lane, London.

25361. **Improvements in electrically-driven hydraulic pumps for operating lifts, cranes, and the like.** Percy John Crundall Day and Bernhard Wiesengrund, Temple Bar House, Fleet-street, London.

25365. **Improvements in trolleys or current collectors for electrically-driven vehicles.** Sydney Brittain Forwood, 6, Lord-street, Liverpool.

25383. **New or improved receiving apparatus for explosive submarine and land mines operated by electric waves.** Ferdinand Schneider, 31, Bedford-street, Strand, London. (Date applied for under Patents Act, 1901, Jan. 23, 1905, being date of application in Germany.) (Complete specification.)

25392. **Improved apparatus for illuminating photographic studios with electric incandescence lamps.** Philipp Georg von der Lippe, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

25393. **A device for limiting the speed of series alternating-current electromotors.** Elektrizitäts Akt.-Ges. vorm. W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901 Dec. 27 1904, being date of application in Germany.) (Complete specification.)

25405. **Improvements in and relating to systems of electrical distribution.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (General Electric Company, United States.)

25406. **Improvements in motion-checking devices especially applicable to steering mechanism of vehicles.** The British Thomson-Houston Company, Limited 83, Cannon-street, London. (General Electric Company, United States.)

DEC. 7.

25412. **A new or improved vacuum tube or tubes for the production of violet or ultra-violet rays X-rays, or other rays or combination of rays on high or low tension currents.** John Cunningham Bowie and John Henry Phelps, 1, Montgomery-street, Cardiff.

25415. **An improved method of controlling the trolley poles of electric cars and the like.** Solomon Henshaw and Joseph Swindells, 350, Catherine street, Ashton-under-Lyne.

25471. **Improvements in electric switches.** Francis Joseph James Gibbons, 22, Southampton-buildings, Chancery-lane, London.

25484. **Improvements in or relating to mouthpieces for telephones.** Paul Jacques Mantle, 33, Chancery lane, London.

25490. **Improvements in and relating to wireless telegraphy.** Sir Oliver Joseph Lodge, Knight, and Alexander Muirhead, 323, High Holborn, London.

25502. **Improvements in contact-breaking devices for the magneto-electric ignition of internal-combustion engines.** Dresdner Gasmotorenfab. vorm. Moritz Hille, 31, Bedford-street Strand, London. (Date applied for under Patents Act, 1901, May 22, 1905, being date of application in Germany.) (Complete specification.)

25512. **Improvements in and relating to controlling apparatus for electric circuits.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

25513. **Improvements in electric motor control systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

DEC. 8.

25521. **Improvements in electric switches.** Arnold Greaves Hansard and Henry Sinclair Watson, 53, Victoria-street, Westminster, London.

25522. **An improved method of connecting split or inspection fittings used in the erection of tubing for electric or other work.** William Clayburn Williams, Eidsforth, Park-avenue, Bridlington.

25525. **An electrical automatic signalling apparatus for tramways.** Matthew Rathborne and Henry Fielding, 92, Stockport-road, Denton, Lancs.

25533. **A new or improved monetary recorder for use in combination with the ordinary telephone instrument.** Joseph Henry Langley and Ernest William Mason, 4, St. Ann's-square, Manchester.

25550. **An improved electromagnetic power hammer, drop stamp, or press.** Thomas Henry Large, 154, St. Vincent-street, Glasgow. (Complete specification.)

25561. **Improvements in and relating to methods of cooling and ventilating electric machines.** Siegfried von Ammon, Oswaldestre House, Norfolk-street, Strand, London.

25570. **Improvements in circuit breakers and indicators for use with electric alternating-current circuits.** Leonard Andrews, 38, Deansgate, Manchester.

25581. **Improvements in means or apparatus for electric lighting.** Haydn Thies Harrison, 46, Lincoln's-inn-fields, London.

25612. **Improvements in Rontgen-ray apparatus.** Wallace Cranston Fairweather, 65, Chancery-lane, London. (The firm of C. H. F. Müller, Germany) (Complete specification.)

25614. **Improvements in fuse and switch mechanism.** Callender's Cable and Construction Company, Limited, and John Charles Augustus Ward, 24, Southampton-buildings, Chancery-lane, London.

DEC 9.

25615. **Improvements in electric arc lamps.** George Davis, 15 Victoria street, London.

25636. **Improved means for preventing the "live" wires of electric tramways from descending to the common danger of pedestrians and others when broken or severed.** Samuel Sims, 17, Hanover-street, Keighley, Yorks. (Complete specification).

25641. **Improvements in and relating to electrical distributing systems.** Leonard Andrews, 38, Deansgate, Manchester.

25669. **Improvements in and relating to conduits or casings for electric conductors.** Richard Henry White Knight and Ludwig Nagel, 323, High Holborn, London.

25670 **Improvements in or relating to secondary or storage batteries.** The N S. Electric Storage Company and Job Thomas Niblett, 139, Queen Victoria-street, London.

25676 **Improvements in electric controlling devices for cars.** James Barry Keighley McCollum and John Wycliffe Lowes Forster, 4, South-street, Finsbury, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Dec. 28.

1904.

26686. **Electric telegraphs.** Siemens Bros. and Co., Limited, and Grimston.

26748. **Apparatus for controlling telegraphic recorders and other instruments.** Marconi's Wireless Telegraph Company, Limited, and Priddle.

27400. **Systems of electric motor control.** British Thomson-Houston Company, Limited. (General Electric Company.)

27844. **Method of controlling electric lifts, elevators, conveyors, or any similar contrivance having a moving car and stations** Jacoby.

28687. **Means or apparatus for automatically starting, controlling, and stopping single or multiphase alternating-current electric motors.** Carr and Birch.

1905.

523. **Electric oil and like switches.** British Thomson-Houston Company, Limited. (General Electric Company.)

NOTES.

Dick-Kerr Engineering Society.—On Saturday last the members of this society held their first social evening, which took the form of a smoking concert, all the songs being rendered by members of the society. A very enjoyable evening was spent. Mr. Cox, of the testing department, was in the chair.

Northampton Institute Engineering Society.—The third fortnightly meeting of this society was held on the 15th, Dr. C. V. Drysdale in the chair. Mr. A. E. Jolley read a very interesting paper on "Points in Connection with the Testing of Electrical Machines." In the course of his paper the author dilated largely on the subject of error in electrical measuring instruments. He also pointed out the difference between accurate laboratory testing and commercial testing. The paper was followed by a discussion.

Trade Marks.—A correspondent in the *Globe* draws attention to an evasion of the Merchandise Marks Act, the seriousness of which it is hard to exaggerate. Certain electrical instruments are imported from France with the words "Made in France" stamped on them. But the stamp in question can easily be removed, and underneath appears the legend "Made in England." Accordingly, the unsuspecting purchaser believes that he is using home-made goods, when, in fact, not even the lying inscription has been made here. This appears to be a form of dishonesty which is becoming all too common among unscrupulous manufacturers abroad which is difficult to characterise in sufficiently strong terms.

Electro-Harmonic Society. — At this society's smoking concert last Friday evening a pleasant feature was introduced. During the interval, the chairman, Mr. John Gavey, C.B., presented prizes to the executive committee of the recent electrical exhibition in commemoration of their great success at Olympia. Mr. Cunliffe Owen was presented with a gold chronoscope, and Mr. C. S. Northcote with a gold combination matchbox and sovereign case, while each of the committee and the secretary received a gold matchbox. Mr. Gavey said that the exhibition had created a demand for electrical things which were before unknown to the public, and that the industry had received a strong impetus thereby. Mr. Owen responded on behalf of the recipients.

Royal Meteorological Society.—The monthly meeting of this society was held on the 20th inst. at the Institution of Civil Engineers, Great George-street, Westminster, Mr. Richard Bentley, F.S.A., president, in the chair. Mr. G. C. Simpson gave an interesting account of his attempt to fly kites for meteorological purposes from the mission ship attached to a deep-sea fishing fleet in the North Sea. These observations, which were made in July and August last, were carried out on behalf of the Joint Kite Committee of the Royal Meteorological Society and of the British Association. The other papers read at the meeting were: "Temperature Observations during the Partial Solar Eclipse, Aug. 30, 1905," by W. H. Dines, F.R.S.; "Comparison between Glaisher's Factors and Ferrel's Psychrometric Formula," by J. R. Sutton, M.A.; and "A Rapid Method of Finding the Elastic Force of Aqueous Vapour, etc., from Dry and Wet Bulb Thermometer Readings," by John Ball, Ph.D.

Electric Tramways in Japan.—It is stated that the Yokohama Electric Tramway Company have closed a contract with the Japanese engineering and contracting firm of Messrs. Takata and Co., Tokio, for some additional rolling-stock. Six No. 21-E Brill trucks, having a gauge of 54in., wheel base 6ft., diameter of wheel 30in., axles 3¾in., have been contracted for. Upon these trucks will be mounted 18ft. closed car bodies, the length over platform being 25ft. and the width from out to out of sills 6ft. These car bodies will be built in Japan, and the trucks will be arranged to take Sterling brakes, which have been ordered from America. The motor equipments for the trucks have been ordered from the Westinghouse Electric and Manufacturing Company, and consist of six double motor equipments, each of two Westinghouse 12-h.p. and 25-h.p. railway motors, the motors to be nose suspension, and complete with suitable gears, gear cases, pinions, etc. Each equipment will be supplied with two Westinghouse No. 211 brake controllers, and will also be supplied with double trolleys, with 14ft. poles, the distance between trolley wires being 18in. A large order for spare gear and motor parts has also been placed with the Westinghouse Company. For the trucks of these cars, Messrs. Takata and Co. have ordered six pairs of Van Dorn automatic drawbars No. 5, with ball joint, suitable for pulling a trailer weighing 20 tons. The greater portion of the equipment has been ordered from America, and it seems evident, judging by the number of contracts which are placed in that country and on the Continent, that our electrical manufacturers are not benefiting from the development of Japan.

Electric Locomotive Tests.—The *Street Railway Journal* gives the results of some tests on energy consumption recently conducted in Switzerland with a 45-ton single-phase converter electric locomotive built at the Oerlikon Machine Works. The values given are the averages of a large number of readings which were taken at the terminals of the trolley line at the primary station:

Speed.		Weight of train, including locomotive,	Grade	Energy
Kilowatts per hour.	Miles per hour.	in metric tons.	per cent.	consumption in kw.
42	25·0	45	0	90
42	25·0	45	0·8	139
37	22·9	120	0	90
37	22·9	120	0·8	129
32	19·8	160	0	190
32	19·8	160	0·8	235
30	12·4	250	0·8	320

The locomotive takes current from an overhead contact line at 15,000 volts, and is equipped with a single-phase synchronous motor, direct connected to a direct-current generator, which drives the direct-current motors and axles. The locomotive which is being given a test run had made up to Oct. 1 4,850 km. (3,031 miles), corresponding to 486,000 ton-kilometres. During these tests no difficulties have arisen either with the locomotive or with the overhead line, in spite of the high voltage used.

Long-Distance Telegraphy.—The electrical engineer's branch of the General Post Office, Melbourne, Australia, furnishes an account of long-distance telegraphic work on Australian lines on Sept. 24. The circuit nearly encircled the continent, from Cape York on the north-east tip to Broome on the north-west. The length was 6,601¼ miles, in which there were 13 repeating stations. The experiments were begun at 11 a.m. Melbourne, Sydney, Brisbane time, which under the prevailing zone system was 9 a.m. at Perth. Adelaide, Melbourne, Sydney, Brisbane, and Townsville were in attendance and ready at the former hour, and greeted each other. Cape York was then joined to the circuit, the signals to and from being clear and firm. Owing to an unexpected delay at Eucla, which is a main repeating station situated on the Great Australian Bight, communication between Perth and Melbourne and the other capitals was not possible until 12 noon, but when this was possible there was no difficulty in speaking through to Cape York freely and well: Broome, a duplex station, 1,466 miles distant from Perth, was then connected to the circuit, and it and Cape York passed the time of day and carried on a con-

Digitized by Google

versation for 15 minutes, at a key speed of 20 words per minute, without the least sign of lag in the signals. Broome stated that the temperature was 100deg. in the shade there, while Cape York set it down at 80deg. at that end. The signals passed from one terminal station to the other splendidly, annihilating distance in a most pronounced manner, and amply demonstrated to the satisfaction of all concerned that through telegraph working from one end of Australia to the other was a practicable feat. With the arrival of this successful issue the terminal stations were taken off, the intermediate circuits were dismantled, and the experiments came to an end.

Printing-Machine Noises.—An interesting case was heard in the Court of Appeal on Friday last, which in view of the extending application of electricity for driving printing machines is worthy of more than passing attention. The particular question raised by the case was whether a person electing to reside in a trade neighbourhood, such as a neighbourhood occupied by the printing and allied trades, is entitled to complain if he finds the noise is substantially increased. The appellants were Messrs. Polsue and Alfieri, printers, who sought a reversal of a judgment of Mr. Justice Warrington, who found that a substantial addition to the noise created a nuisance, and, therefore, granted a perpetual injunction. Lord Justice Vaughan Williams, in the Appeal Court, said that even if the night noise caused a serious disturbance to the plaintiff and his family, it would not be a private and actionable wrong provided the noise arose out of carrying on the work in the particular and established manner of the trade of the district. He also said that plaintiff's compensation for submission to the noises lay in the fact that he entered the district to gain a livelihood by supplying his wares to the people who made the noises. Lord Vaughan Williams said he did not think Mr. Justice Warrington had applied the principles established by preceding cases, but that was not sufficient ground for reviewing his decision. The other judges concurred in this, and the appeal was dismissed. The machine complained against was of the Miehle type, driven from a 7½-h.p. motor coupled direct and fixed upon a concrete bed. The evidence of experts showed that the machine was much quieter than many of its kind, whilst others in the neighbourhood averred that the nuisance complained about did not, in fact, exist. It would be as well to have an authoritative judicial expression of opinion on the rights of the parties.

Three-Phase Railways in America.—The first electric railway to use three-phase alternating currents in America will, says the *Electrical World and Engineer*, run between London and Port Stanley, Ontario, Canada, and it is expected to open one part of the line for service in about two months. This railway, besides being the first exponent of the three-phase system, has another feature of special interest. The length of line now under construction is 27 miles, split into two sections of 18 miles and 9 miles, to be run with three-phase currents. Between these two sections there is a third one of about two miles, belonging to the St. Thomas City Railway, and run by direct current. The cars of the interurban road will run over the direct-current section too, being furnished with a special equipment permitting this. The motor stator has a three-phase winding arranged in such a way that it may be fed with 1,000 volts alternating current or 500 volts direct current. The rotor has a commutator and four sliding contact rings, it being a two-phase armature when running with alternating current. Each car will have two of these motors, of an aggregate rated horse-power of 130. The series-parallel control will be used for direct-current work, and the single cascade control for alternating-current running. The trains to be hauled will weigh 35 tons, and run at a maximum speed of 30 miles per hour. The line has several very heavy and long grades up to 5 per cent. The transmission and distribution E.M.F. is 10,000 volts, three-phase. This railway represents a novel application of the Ganz system, as it is a combination of alternating current and direct current that will enable the interurban road to enter the cities and its cars to pass over the street railway lines. It is expected that the railway company will soon extend its line east as far as Hamilton, a distance of 85 miles, using the same system.

Uses of Electricity.—Mr. S. E. Fedden, general manager of the Sheffield Corporation electric supply department, recently delivered an instructive lecture on "Electricity" to the members of the Sheffield Society of Architects and Surveyors. He emphasised the importance of electrical engineers instructing their customers to appreciate the advantage of good lamps over second-rate ones. We are glad to observe that engineers of corporations and supply companies are realising this necessity, and the list of instructions to consumers recently issued by the Chesterfield electrical engineer, to which we called attention a few weeks ago, is, so far from being an exception, the recognised practice among up-to-date supply corporations. Mr. Fedden made some practical remarks anent the arrangement of electric fittings in houses and shops, which, he said, showed utter disregard of fitness and a complete ignorance of the first principles of illumination. There was room for specialists in this class of work who could give more attention to the arrangement of lights with a view to economy. He combated some of the extravagant statements made by vendors of gas and gas appliances in support of their claims. Occasionally definite cases were cited where a saving had been effected by the substitution of some of the most recent forms of gas lighting, but it was generally found that the customer had contented himself with less light. In electric lighting great economies could be effected, and if these economies were adopted electric light accounts would go down. Moreover, there were other advantages. It was said that by introducing electric light Mr. William Whiteley, of London, saved £5,000 per year on painting and whitewashing. There was also the question of health. He was able to say, from practical experience, that in Sheffield in nearly every case where electric light had been installed in a church or chapel there had been a saving as compared with gas.

The Steam-Turbine.—The evolution of the steam-turbine, the general theory of its working, and some of the chief features of the flow and expansion of steam, and the conditions essential to economy, were touched upon in a paper on the steam-turbine prepared by the Hon. C. A. Parsons, C.B., F.R.S., and Mr. G. G. Stoney, M.I.C.E., and read before the meeting of the Institution of Civil Engineers on the 5th inst. After describing and discussing the chief characteristics of the three types of steam-turbine, which practically cover the whole field of useful turbine inventions, a table and diagrams were shown to illustrate the manner in which steam consumption is influenced by the size of the plant and the degree of vacuum obtained. The importance of a good vacuum to the economical working of steam-turbines was urged, and the authors pointed out certain special conditions and arrangements which must be observed in order to obtain a vacuum of 27½in. to 28in. An apparatus called a vacuum augmenter was described, which has been designed by the authors, and which consists of a steam jet placed in a contracted pipe between the condenser and the air pump. With this apparatus, a total net reduction of steam consumption of about 8 per cent. at full load has been obtained. Various applications of steam-

Digitized by Google

turbines for driving pumps and for working fans for colliery ventilation and blast-furnace work were also alluded to. The remainder of the paper dealt with the application of the steam-turbine to marine propulsion. The various phases in the development of the steam-turbine for this purpose were traced, and the several vessels to which it has been applied were described. The experience gained from the cross-channel steamers and yachts showed that turbine vessels possess the valuable characteristics, that the propellers do not race in a heavy seaway, that the vessels maintain their smooth water speed to a remarkable extent in heavy seaway, and that they start, stop, and manœuvre promptly. The paper was illustrated by drawings showing the arrangements of turbine machinery suitable for an Atlantic liner, a cross-channel steamer, and a warship.

Books Received.—"Dynamo-Electric Machinery," by Prof. Silvanus P. Thompson, seventh edition, vol. 2 (E. and F. N. Spon, Limited, London. 30s. net). The present edition has been practically rewritten, and out of the 800 pages contained in the sixth edition less than 100 pages have been retained. This has been necessitated by the vast extension of alternate-current machinery which has taken place during the last nine years. The book is profusely illustrated, and contains a copious index.—The December issue of the "Tyneside Electrical Pioneer" is a specially prepared Christmas number, and the cheering cover and text are appropriate for the season. This little magazine is published by the Newcastle-upon-Tyne Electric Supply Company, Limited, whose enterprise has done much towards the extension of electric lighting in their district, and in its pages are some interesting little articles.—The September issue of the "Technology Quarterly and Proceedings of the Society of Arts" (America) contains a number of interesting papers and notices.—The *Journal* of the Western Society of Engineers (Chicago) for October contains a report of the International Railway Congress of 1905, and a paper by Mr. James R. Cravath on "Illuminating Engineering," together with other contributions and abstracts.—In the December number of the *Wisconsin Engineer* there are a number of interesting papers, including one by Mr. F. E. Turneaure on the "Progress of the College of Engineering," from which we see that the electrical laboratories are being enlarged and additions to standard equipments in the dynamo laboratories are being made, with considerable improvements in the department of electrical testing.—The December number of the journal of the Central Technical College Old Students' Association, known as the *The Central*, makes a belated appearance, due to the fact that one of the editors has only recently returned from South Africa. It contains a portrait of Prof. W. E Ayrton and articles on "Electromagnetic Separation of Ores" (illustrated) by Mr. C. J. Guttmann, the "Castleblaney, Keary, and Armagh Railway," by Mr. K. Rise-Oxley, etc. The Harvard Engineering *Journal* for November includes contributions on "Hard-Drawn Copper Wire" by Mr. T. B. Doolittle, and the "Distribution of Pressure and Current over Alternating-Current Circuits" by Dr. A. E. Kennedy.

German Patent Practice.—Complaints are made by American inventors at the treatment of their German patent applications, and the report of Consul-General F. H. Mason, in which he makes comparisons between the United States *v.* German Patent Office practice, shows justifiable grounds for the complaints. He says that it is not uncommon to hear American and other foreign inventors complain of a hostile and forbidding attitude on the part of the examiners at the German Patent Office, as though the duty of the latter were to assume that every invention presented for a patent is defective or plagiarised until the contrary is proven—in other words, to discourage rather than encourage the protection of meritorious inventions by patent. He then cites some of the difficulties under which American inventors labour, and as the same terms apply to all foreigners, it may be of interest to English inventors to bring them to light. In the first place, a foreign inventor may not deal directly with the Imperial German Patent Office. He must be represented there by a patent attorney of recognised standing, by whom the application and specifications are presented, and through whom additional details or explanations may be asked for by the examiners. There is kept at the German Patent Office a list of recognised patent attorneys who are located in Berlin and throughout the Empire. Secondly, specifications and claims for patents on American inventions, says Mr. Mason, are frequently presented in the form of translations made by persons who have only an acquired and superficial knowledge of German. Such translations, made with the aid of a dictionary, mechanically translate the words, and not the meaning, of important phrases, so that the specifications and clauses as filed are often incomprehensible. This entails additional correspondence, corrections, and frequently long delays which might have been obviated. Few persons, comparatively, are capable of translating a technical description so that it shall mean exactly the same in a foreign language as in the original, and it is this want of exact completeness that often loses a foreign patent or renders it, if gained, loose in its provisions and impaired in value. The subject is one which commands universal attention, and a clearer understanding of the requirements of the patents laws of the various countries would avert loss of time and money and avoid the possibility of friction and litigation.

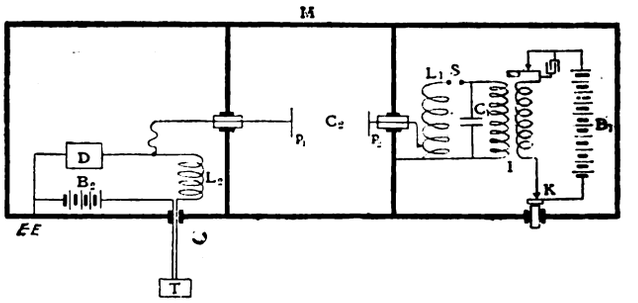
Electrical Development in South Africa.—In an interesting United States consular report, Mr. Consul Snodgrass states that, although British firms have been capturing the majority of contracts in South Africa, the United States can come in for a larger share of the trade by the prosecution of an energetic campaign and by having competent men in the field. The great activity in the electrical trade, reports the consul, is not by any means confined to South Africa, for in Egypt and other northern provinces large electrical problems are under consideration. As an instance, the Soudan Government are considering the introduction of an extensive electric tramway system into Khartoum. Neither cables nor overhead wires will be used, the intention being to store the electric power in the cars. It is expected that the system will be extended to Omdurman. In South Africa, especially in the Transvaal, the demands on electrical engineers are multiplying to an enormous extent. There appears to be a feeling of optimism among the small cities as well as among the larger ones, which is bringing about a larger expenditure for utilities. Electrical hoists are being installed in nearly all the mines, electrical elevators are being placed in many of the business houses and in the tall buildings of Johannesburg, and in nearly every town of any importance some large electrical project is either in hand or in contemplation. In the city of Pretoria the citizens have been worrying along with a horse-car line, which penetrates the centre of the city, and has, perhaps, three miles of track. The Town Council are arranging to convert it into an electrical system at an outlay of several millions, it being the intention to lay 15 or more miles of track throughout the municipality, and also to connect the numerous suburbs lying within a radius of five or six miles. At Johannesburg several millions were spent in installing an electric tram system, but Mr. Snodgrass laments the fact that practically all the contracts were captured by representatives from Scotland and England.

Digitized by Google

At Volksrust and Klerksdorp it has been decided to erect lamps. The report goes on to urge Americans that if they care for this trade they will have to wage a war for it against the Britishers, who are on the ground, and are in possession of the country. It concludes, however, that as America has captured the mining machinery trade on the Rand from all competitors, even under British rule, it can do likewise in the electrical field if the same amount of energy, concerted effort, and brains are expended as were laid out by the pioneers in the goldfields.

Power at the General Post Office.—Any interference with a continuous supply of power to the General Post Office would result in an inconvenient dislocation of the whole postal system of London, and the authorities at St. Martin's-le-Grand, realising this, have embarked upon a scheme for the provision of power from their own generating station. The question of cost has to some extent influenced them in their decision, for it is claimed that the change will result in a saving of 75 per cent. What the Post Office requires is practically a day and night load, because in the daytime the power plant is in full operation, and during most of the night current is required for lighting the premises. In this way they approach the central-station engineer's ideal of a very economical load factor. The present generating plants located in the various buildings will be disestablished, and, quite apart from the question of safety to the buildings themselves, there is to be considered the nuisance which is caused by the emission of steam and coal dust, so that removal should be welcomed. The new scheme provides for the supply of current for lighting and power purposes to the three Post Office buildings in St. Martin's-le-Grand, the new structure now in course of erection on the site of Christ's Hospital, and the Post Office buildings in Queen Victoria-street, but it is not contemplated to supply current to the depôt at West Kensington. The power station will be at Upper Ground-street, Blackfriars, on the river bank, which will admit of barges with coal coming alongside, and also of the use of river water for condensing purposes. A plant equal to about 3,600 h.p. will be installed, but the station is designed for indefinite extension. At the outset it is not proposed to use turbines, because for the number of units necessary to avoid the possibility of temporary stoppage, turbines would be too small to be economical, as compared with reciprocating engines. At the present time one chimney, 180ft. in height, has been completed, but the proposal is ultimately to have a second chimney as a stand-by. Buildings and plant together will cost £100,000, and this figure takes no account of the cost of the site. The power station will be within a mile of the General Post Office, which means that the cost of the cables will not be excessive. They will be duplicated throughout, and with the exception of Blackfriars Bridge, where they will cross the river, they will be laid in separate streets. This is naturally intended to avoid the risk of breakdown in the case of any accidental damage to cables. Across Blackfriars Bridge itself the cables are to be carried on opposite sides of the roadway. As regards voltage, the proposal is to generate current directly at 6,000 volts, and to transform down at the Post Office to suitable voltages for power and lighting purposes. A very considerable proportion of the current will be used for compressing air for pneumatic tube transmission. At present practically all the central London work in connection with the telegraph service is dispatched by pneumatic tubes, but proposals are under consideration for dealing with the letter work between the General Post Office and Mount Pleasant in the same way. Another of the applications of electricity in the Post Office is for working air-compressing engines for the pneumatic dispatch plant, lifts, fans, stamping machines, and a multiplicity of small appliances used for a great variety of purposes. A machine worked by an electric motor is now employed in obliterating the postage stamps on letters at a speed of 600 letters per minute, a work which in the old days was entirely done by hand at, say, 50 to 60 letters a minute. The project is being carried out entirely under the direction of Mr. J. Gavey, C.B, M.I.C.E, the engineer-in-chief to the Post Office, and Mr. Martin Roberts, M.I.C.E, the assistant engineer-in-chief.

Testing Wireless Receivers.—Mr. Greenleaf W. Pickard has conceived a new method of testing wireless receivers, which he describes in a recent number of the *Electrical World and Engineer*. Hitherto it has been the common practice among experimenters to set up miniature sending and receiving antennæ placed a short distance apart, energising the sending antenna, a simple ungrounded Hertzian oscillator, by means of a small induction coil. The method employed by Mr. Pickard utilises a closed oscillating circuit adjusted to the desired frequency, which is carefully shielded from the detector under test, but is connected thereto through a circuit of impedance so great that the resistance of the detector forms but a negligible part of the impedance. This is accomplished by inserting a variable air condenser of extremely low capacity in the circuit. Under these conditions the flow of current through the detector is governed solely by the value of the capacity, the impressed E M F., and the frequency. As the oscillating circuit, the air condenser, and the detector are separately shielded from each other and from external objects, the electrostatic capacities of these circuits are fixed quantities, with the exception of the air condenser, and movements of



the observer are, therefore, without effect. The diagram illustrates the arrangement of apparatus, circuits, and shields. M is a shield of tin or sheet zinc, forming a rectangular box with three compartments, which are fitted with metallic covers or doors giving ready access to the compartments. The compartment on the right contains the battery, key, and induction coil, together with the oscillating circuit. The induction coil, I, the spark length of which is preferably 1in. or less, charges the condenser, C_1, which discharges across the spark-gap, S, through the inductance helix, L_1, thereby setting up oscillations of a frequency depending upon the values of the capacity and inductance. One terminal of the inductance helix is connected to the shield, while from an intermediate point along the helix a lead is taken through the detector to be tested, one terminal being connected to the plate, P_2, of the variable air condenser, C_2, in the middle compartment. The other plate of this condenser is made movable, being attached to a stout wire which slides easily in the glass tube leading to the left-hand compartment. In this latter compartment is placed the detector to be tested, one terminal being connected to the plate, P_1, of the air condenser, and the other to the shield. The local circuit of the detector passes out of the shield to the telephone receiver or galvanometer, T, a suitable choke coil, L_2, being interposed on the air condenser side of the detector. With the exceedingly sensitive

Digitized by Google

detectors now used in wireless telegraphy, the current strength required to give an observable signal is very small. By making the plates, p_1 p_2, in the form of metal discs 1cm. in diameter, and separating them several centimetres, the capacity may be reduced to less than one-hundreth of a micro-microfarad, and the current to a fraction of a micro-ampere. Mr. Pickard claims that this method also affords a source of oscillatory current suitable for testing tuned receiving circuits, giving current values comparable with those obtained in commercial wireless telegraphy over long distances. As the damping in the oscillating circuit is comparatively small, the oscillations are persistent, corresponding to those used in high-power wireless stations.

Wharf Cranes.—Facilities for transportation by land and sea have made considerable progress, but the development of the means for transferring goods from one great carrier to another has not been commensurate with the demands. Some of the greater steamship lines have very recently equipped their wharves with electric hoists, and signs are not wanting to show that both railway and steamship companies are awaking to the fact that they must make the necessary expenditure for freight-handling machinery if the work is to be done economically. About two years ago the Pennsylvania Railroad Company began to construct a new freight terminus in the New York Harbour at Greenville, N J., to be operated electrically.

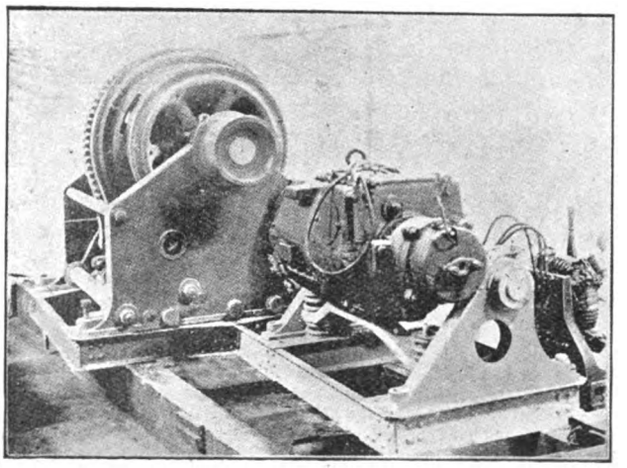


FIG 1.

Mr. John Lyle Harrington, in a paper which he contributes to the Canadian Society of Civil Engineers, describes the equipment, which he considers the most advanced type yet developed for the purpose. There are three cranes erected upon a pier 120ft. wide by about 1,000ft. long, substantially constructed of timber and especially designed to carry the cranes. Each crane in working order weighs about 125 tons, the height is about 100ft.; they are designed to handle a normal load of 10 tons of package freight and to operate a clam shell bucket of about 60 cubic feet capacity for handling the bulk freight. Each crane is carried on four four-wheel trucks running on two tracks of 14in. gauge. All the engines and the air compressor are electrically operated, and are situated in the rear of the engine-house. The operators, however, are stationed one on either side of the crane. The levers for operating the friction clutches and brakes are led to the operators' stands, where the controllers are also placed. The cranes are provided with electric lights and telephones for inter-communication or for communication with the shore. Each truck is composed of four standard chilled car wheels of the heaviest type, standard 5 × 9 journals, journal boxes and bearings, and a steel frame composd of heavy 15in. channels, substantially braced. Two trucks are provided with air brakes, and each of the other two is fitted with a 25-h.p. railway type motor and cut spur reduction gearing for operating the crane on its tracks (as shown in Fig. 1). The main hoisting engine is designed to handle either the package freight on a one, two, or three part rope, or to operate the clam shell bucket. It is fitted with a solenoid brake and with an exceptionally large and efficient load brake, which prevents the load from running down in case the current should be cut off, or accident should happen to the motor. The engine is operated by a 100-h.p. motor wound for 500 volts direct current and mounted on springs. Fig. 1 also illustrates the third auxiliary engine employed to operate the auxiliary hoist for placing slings under the loads of package freight. The hoisting rope is led directly from the engine to a sheave in the rear of the boom, thence forward to a block suspended by a slide from the underside of one part of the boom. The rope is then led around the running block in the usual manner. The slide is moved along the boom and held in position by a continuous rope running over the sheaves at both ends of the boom and operated by the winch-head on the engine. The

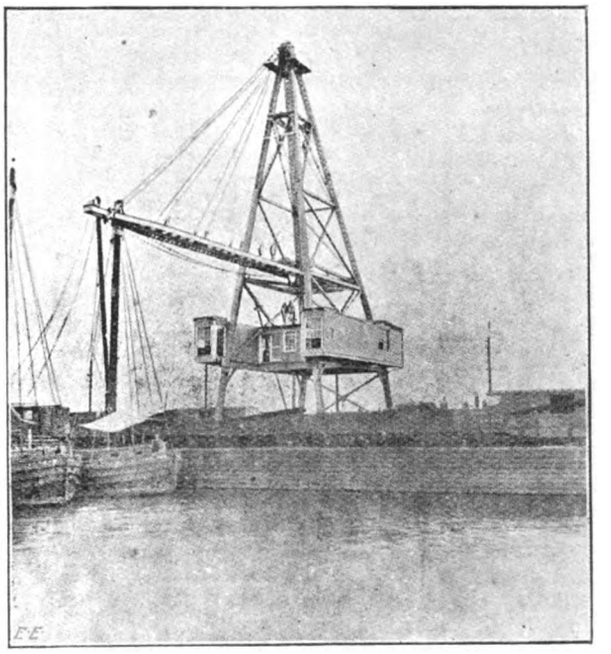

FIG. 2.

boom consists of two symmetrically disposed parts, each composed of an I beam and a channel well braced together. The truck runs on rails placed directly upon the I beams. As shown in Fig 2, the boom extends to the extreme rear of the tower, where the horizontal thrust due to the weight of the boom and the tension in the trolley ropes is carried by a heavy girder. The guy ropes always occur in pairs in order that the hoisting ropes may traverse the length of the boom between them, and they are so attached that the respective halves of the boom are balanced under load, and do not twist. A water-main is carried along the entire length of the pier just beneath the floor, and each crane is provided with universal nozzles, and connections are made so as to render each crane a veritable fire-engine. The cranes were designed to operate on their tracks at a speed of about 180ft. per minute under the greatest estimated resistance. The motors are, however, under series-parallel control, and operate together at full or half speed. The resistance is nominally far below the maximum, consequently the speed of operation is commonly much greater than 180ft. per minute. The machines are large and expensive, but, according to Mr. Harrington, they have so thoroughly demonstrated their merits while they have been in operation, that in future there is little doubt that similar machinery will be employed on all large wharves.

THE LONDON, BRIGHTON, AND SOUTH COAST RAILWAY ELECTRIFICATION.

As was announced by us a fortnight ago, the contract for the electrification of the above railway company's line from Victoria to London Bridge has been placed with the Allgemeine Elektricitäts-Gesellschaft of Berlin. There has been an outcry in the daily papers—organised, we believe, by interested parties—against the placing of such an important contract abroad. The usual plea that English firms were capable of doing the work was put forward. This outcry, however, was quite unjustified, as nine-tenths of the work involved in the contract will be sublet to English firms. The reason why the main contract was placed with the Allgemeine Elektricitäts-

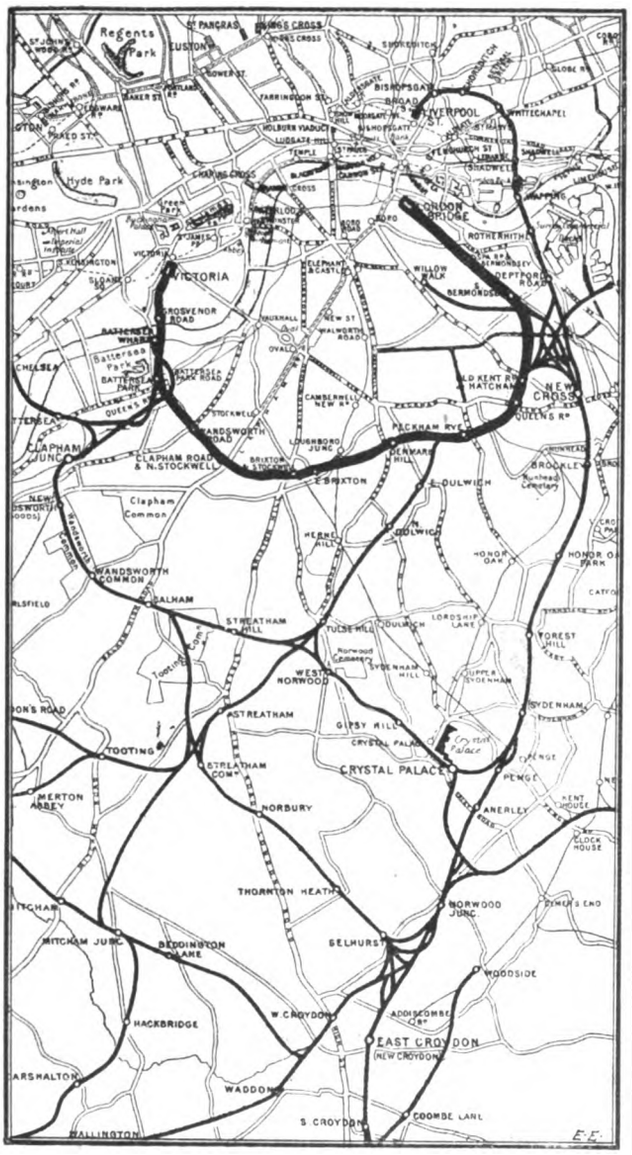

FIG. 1.—Map of the Suburban Lines of the L. B. and S. C. Railway. The portion to be electrified is indicated by the thick line.

Gesellschaft is that their tender for the Winter-Eichberg single-phase system gave more favourable results, both from a technical and commercial standpoint, than any other. This system was originated by the staff of the Union Company of Berlin, which has now been merged into the Allgemeine Elektricitäts-Gesellschaft. The Union Company was the German branch of the General Electric Company of America, which is represented in this country by the British Thomson-Houston Company. We are pleased to notice, therefore, that the British Thomson-Houston Company has a large interest in the present contract, and that all the switchgear will be manufactured at Rugby. The firm are the owners of the British patents for the Winter-Eichberg system. It has been arranged that after the first few equipments have been supplied from Germany, the rest of the motors and the controllers for the trains will be likewise manufactured in Rugby. The reason why the first equipments are to be made in Germany is that they are to be duplicates of those which have already been built and worked successfully by the Allgemeine Company. Hence they can be supplied at a much earlier date than would be possible if they had to be manufactured at Rugby. We are pleased to see that the British Thomson-Houston Company is extending its success as contractors for heavy railway electrifications. Thus they have already been responsible for the equipment of the Central London Railway, the Great Northern and City Railway, the North-Eastern Railway, and the District Railway. The company now has contracts for all the motors and control equipments for the various tube railways controlled by the Underground Electric Railways of London, Limited, and also for the Great Western and Metropolitan Railways for the equipment of the Hammersmith and certain other lines. The number of motors for this class of work which they have furnished or are under contract to furnish in England is nearly 2,000.

Coming, now, to the London, Brighton, and South Coast line from Victoria to London Bridge, we show in Fig. 1 a map of the route, which also includes a number of other lines belonging to the company which will doubtless be electrified after experience on this first route has been obtained. As evidence of this, the contractors, under the advice of their general manager, Mr. W. Forbes, have decided to equip electrically all the lines in both stations. This involves no less than 11 lines at London Bridge Station and 13 at Victoria. Thus the electrical trains will be able to run into any platform. It will also enable the

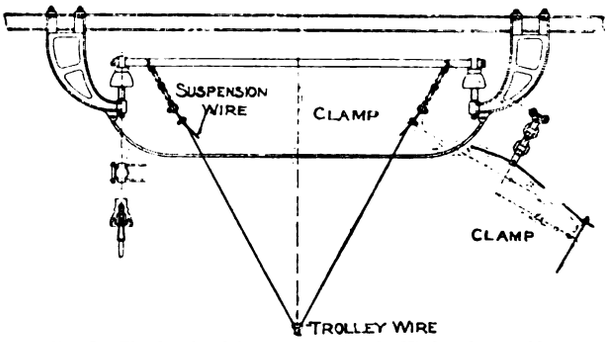

FIG. 3.—The Overhead Construction for the Niederschoneweide-Spindlersfeld Railway

overhead work, as complicated by numerous crossings, to be severely tested before dealing with the whole traffic of the stations in question. It will be seen that the line now to be equipped is one which does not go far into the suburbs, and which has suffered from the competition of the London County Council tramways. It remains to be seen how far the quicker electric service on this route will regain the traffic taken by the tramways. In our opinion the great value of the present electrification is that it is to be carried out on a system most suitable for extension not only to the suburban lines shown on the map, but also, if need be, to the main lines to Brighton and elsewhere. As far as the present route is concerned, there will be two distinct gains from the electrification. Owing to the very high acceleration which the electric motors will give, the average speed of the trains will be doubled. This is a great advantage, but a still greater gain is expected at the two end stations, London Bridge and Victoria. With the steam trains it has been proved that the time which must elapse between the train coming into the station and going out again is six minutes. A good portion of this time is spent in the shunting of locomotives, which, of course, can only be done with due consideration to other traffic on the lines. We reproduce in Fig. 2 a plan of the London Bridge Station, which shows how numerous and complicated are the crossings at the approach. With the new electric trains now proposed this six minutes' interval between the arrival and dispatch of the trains is expected to be reduced to two minutes. If this expectation is realised, it is equivalent to increasing the size of the station. In other words, the existing lines and platforms will be able to deal with two or three times the number of

Digitized by Google

trains in the busy hours. If the value of this gain were capitalised and compared with the cost of extending the station and lines to get the same facility, the financial result would more than justify, in our opinion, the whole cost of the present conversion.

In this electrification the directors have been advised by Mr. Phillip Dawson (of the firm of Messrs. Kincaid, Waller, Manville, and Dawson), and all concerned have taken a good deal of trouble to arrive at the best system. Practically all the firms capable of undertaking work of this magnitude have tendered. They have been given a free hand to enable them to show the best results with the particular high-voltage system with which they have had experience. The examination of these tenders has hence involved a great deal of arduous labour, and the victory of the Winter-Eichberg system must be very gratifying to those firms owning the patents. We are reproducing after this article the paper presented by Mr. F. Eichberg to the International Electrical Congress in America at the end of last year.* In this will be found a full description of the essential features of the system, and a reference to a number of railways which have been equipped on the Continent. Fig. 3 shows the details of the overhead conductor on the Niederschöneweide-Spindlersfeld. The three photographs (Figs 4, 5, and 6) are of the Stubaital line near Innsbruck. They are taken from an excellent description of this line appearing in the current issue of *Elektrische Bahnen u. Betriebe*, which we hope to reproduce in full in our next issue. With this information our readers will have little difficulty in following the general principles of the system to be used on the London, Brighton, and South Coast Railway, and they will also see the details of work successfully accomplished by this system on the Continent. The conversion of this English line, however, presents novel points, and these have to be specially solved. It will be quite time to go into full details when the solution of these problems is an accomplished fact, rather than now, when approved drawings only exist. It suffices now, therefore, to give general outlines rather than actual details. The current required for this line between Victoria and London Bridge will be purchased from some supply undertaking, but no contract for this has yet been settled. The voltage on the single-phase overhead conductor will be from 6,000 to 6,500 volts, and the frequency of the alternating current will be 25 complete periods per second. The overhead construction will be of an entirely new type and remarkable for its great strength. The catenary construction is to be developed into practically a suspension bridge of sufficient strength to carry quite a number of men even midway between two supports. The sub-contract for this work has been placed with Messrs. R. W. Blackwell and Co., which will ensure that no detail will be lightly adopted or allowed to pass without most careful examination. The actual design of the overhead construction had been considered and provisionally sanctioned by the Board of Trade.

Coming now to the trains themselves, the unit in the building up of the same will be three carriages, of which two will be motorcars. There will be four motors on each of these cars, making eight motors per train, with an aggregate power of about 1,200 h.p. If need be, two or

FIG. 2.—The London Bridge Station of the L. B. and S. C. Railway, showing Approach.

* A full mathematical investigation by Mr. F. Eichberg of the relative advantages of different types of single-phase motors will be found in our issues for Feb. 26, March 11, and March 18, 1904.

Digitized by Google

three of these units can be joined together to form longer trains. As regards the energy consumption of these trains, full guarantees have been obtained from the contractors, and we are assured that considerations of efficiency and energy consumption per train mile largely influence the decision arrived at. The average power factor was also found to be considerably higher with the Winter-Eichberg system than with any other. The decision, therefore, may be looked upon as a victory for the compensated repulsion type of single-phase motor over the plain series type.

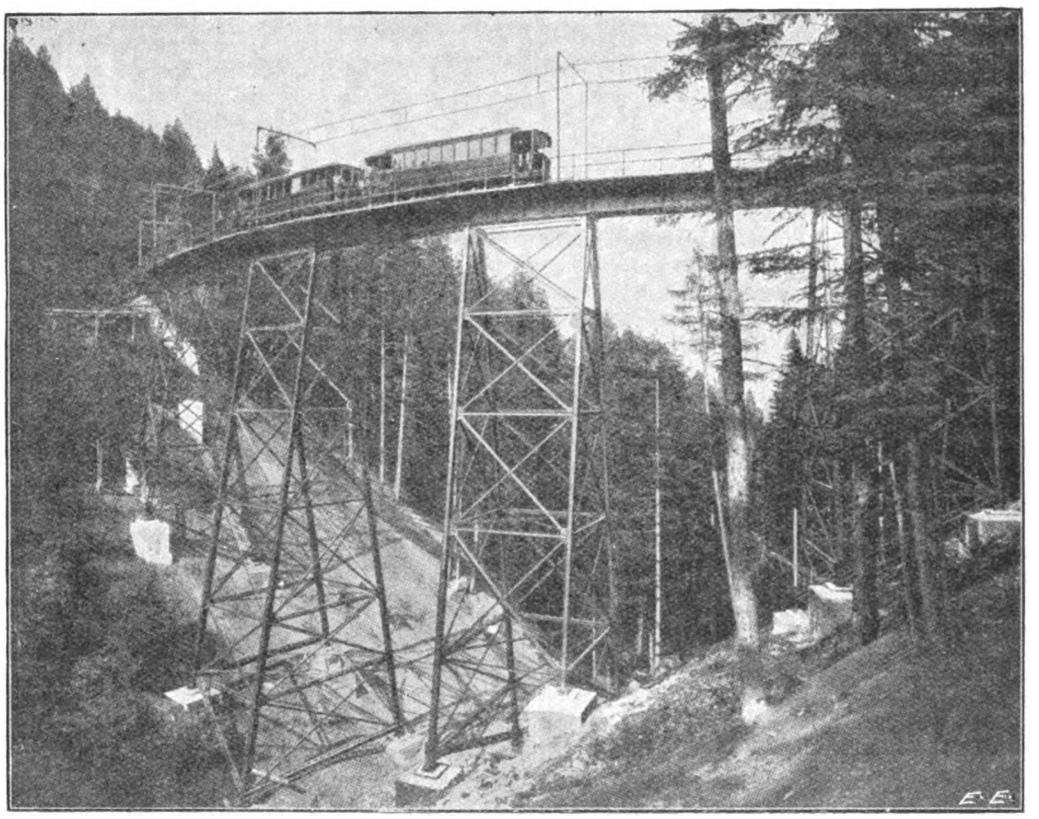

FIG. 4.—The Kreiter Viaduct with Single-Phase Equipment.

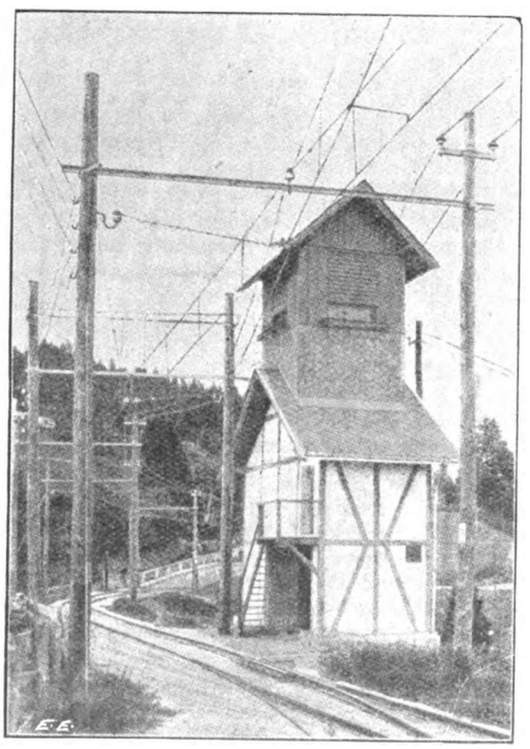

FIG. 5.—A Sub-Station on the Stubaital Railway.

In conclusion, we have to thank Mr. W. Forbes, the general manager of the railway, and Mr. Phillip Dawson, the consulting engineer, for all their courteous answers to our inquiry for information.

SINGLE-PHASE RAILWAY MOTORS.

BY FRIEDRICH EICHBERG.

The standard direct-current railway has probably been developed to its final stage. The combination of alternating current for the transmission of power, rotary converters for the conversion into direct current, and direct-current car motors is not, however, an economical solution except in rare cases. Recognising this fact, Brown and Boveri (Burgdorf-Thun) and Ganz and Co. (Valtellina line) took up the direct application of polyphase alternating currents. But even if the polyphase system has achieved practical success in special cases, it has not been proven thereby that the polyphase motor furnishes a universal

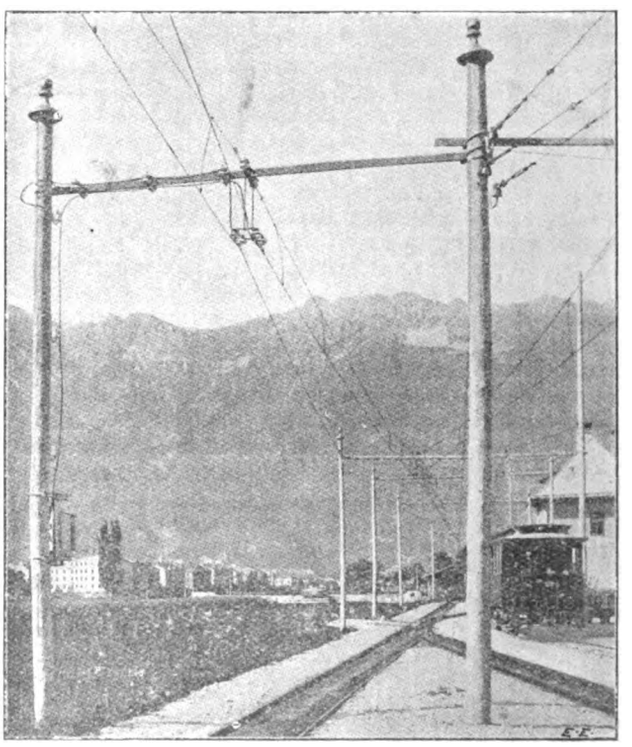

FIG. 6.—The Terminal Station at Wilton, Stubaital.

Digitized by Google

solution of the electric railway problem. It is not necessary here to repeat all the objections that European and American engineers have brought forward in numerous discussions against the polyphase motor. The multiple trolley for the collection of current, which is unavoidable in the polyphase system, leads to complications in the overhead work and sets narrow limit to the line voltage available. For short roads (lines between neighbouring cities) the polyphase system, moreover, leads to excessive cost in the installation of the conducting system. Add to this that the polyphase motor, by reason of its characteristic speed curve, which resembles that of a shunt-wound motor, is almost or quite unfit for railway purposes. It cannot be disputed that it is possible to operate on schedule time upon special lines with a favourable profile, but this proves nothing as to the general applicability of the polyphase motor.

For two years, as is well known, efforts have been made to apply the single-phase motor to railway purposes. B. J. Arnold, with his electro-pneumatic system, and the Oerlikon Company, with the Ward-Leonard system, offered only incomplete solutions of the problem of applying single-phase current to railways. The first announcement of the direct application of single-phase motors came from Lamme, of Pittsburg, and was followed soon after by the publication of Finzi in Milan. The former used a frequency of 16 and the latter 18 cyles per second. Both have built series motors similar to the direct-current series motor. The former uses for the compensation of the armature reaction short-circuited windings, which are applied to the field-magnet coils, and whose axis coincides with that of the brushes. The latter uses slots in the poles for the diminution of the armature reaction. Later the work of G. Winter (see

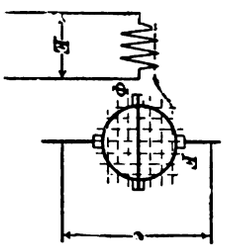

FIG. 1.—Diagram of Winter-Eichberg Motor.

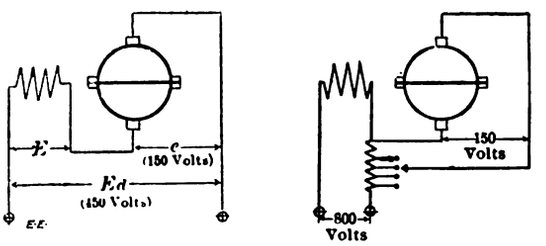
Elektrotechnische Zeitschrift, 1904, No. 4), of Vienna, became known to the writer. This furnished the basis of the system worked out by the Union, and especially by the Allgemeine Elektricitäts-Gesellschaft. This system, which forms the subject of this paper, has been put into operation on the Niederschöneweide-Spindlersfeld line under the management of the Royal Prussian State Railway, and on the Stubaital line, near Innsbrück, which was opened on July 31, 1904. The first line operates with 6,000 volts and 25 cycles, and the second with 2,350 volts and 42 cycles. In perfecting this single-phase system the motor, of course, played the chief part. In a lesser degree the controlling apparatus and those devices which become necessary in the direct application of high tension to the car were also of importance.

In regard to the motor of the Winter-Eichberg system, it unites the properties of the ordinary alternating-current series motor with those of the repulsion motor. Its characteristic features are the following: In the motor, in addition to its own magnetic field, F (Fig. 1), there is developed, as in the repulsion motor, a cross field, ϕ, which at synchronism is about as strong as a magnetic field, F, from which it differs in phase by 90deg. This means that when the motor is near synchronism a complete rotary field is established, the field being less developed below or above synchronous speeds. On account of the cross field developed in the motor, the short-circuited E.M.F. under the brushes diminishes with increasing speed, becomes nearly zero at synchronism, and then increases again with increasing speed. In regard to armature voltage, these motors are essentially similar to the ordinary series motor. In both the tension per commutator segment may not exceed a certain value, and according to the size of the motor the armature voltage will, therefore, lie between 100 and 200 volts. In the ordinary series motor, in which the working voltage appears in the armature, the working voltage would, therefore, not exceed 200 volts. It is otherwise with our motor. Since the armature is short-circuited along the working axis, and the working voltage appears only in the stator field windings, the voltage supplied to the motor may be as great as desired. But even for the case where the excitation is inserted in series with the stator winding (Fig. 2), the entire working voltage, E, is in the same proportion to the armature voltage, *e*, at rest, as the entire volt-ampere input is to the volt-amperes for magnetisation at rest.

Let us suppose that the magnetising current is one-third of the armature current, which is a good practical mean; then the working voltage in the motor of our system, even with the direct introduction of the excitation, is three times as high as in the ordinary series motor. Through the insertion of a small transformer (Fig. 3) one can increase at will the proportion of the working voltage to the armature voltage without great expense (Figs. 2 and 3). The excitation, by means of the armature in combination with the cross field, yields an E.M.F. which is 90deg. ahead of the working E.M.F., and directly opposite to the E.M.F. of self-induction. This wattless counter E.M.F. gives the motor the well-known rapidly rising cos curve (see *Elektrotechnische Zeitschrift*, 1904, No. 4). Our first 100-h.p. motor had with a 3mm. air-space on each side a power factor of 0·9 even at 70 cent. of synchronism. Even more important is the fact that this good power factor is obtained with a number of ampere-turns per centimetre almost twice as great as in the ordinary alternating-current motors. From this results the possibility of building a very powerful motor for a given armature diameter and external dimensions.



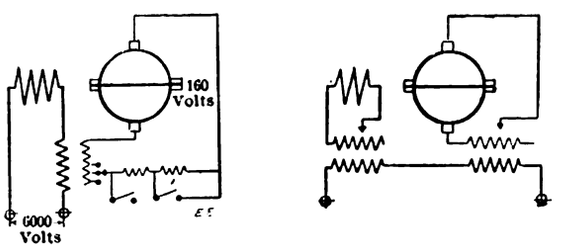
FIGS. 2 AND 3.—Stator Windings.

Another characteristic property of our system is that the field can be controlled independently of the voltage in the working windings. In every alternating-current commutator motor there are magnetic losses in the coils short-circuited by the brushes. Through the possibility of adjusting the field in proportion to the stator current, one can keep these losses under the brushes within such limits as will permit the commutator and the brush-holders easily to conduct away the resulting heat. By varying the field one can, for a given working voltage, give the motor a variable characteristic. The separate characteristic curves will then be somewhat related, as the curves of a 3, 4, 5, and 6 winding motor. Control independent of this naturally is possible, and also control of the load voltage. The accompanying diagrams give examples of the control as carried out in practical cases. In Fig. 4 the primary voltage is not regulated, and only the secondary winding of the exciting transformer is altered. The absence of any primary regulation in the high-tension circuit offers the special advantage that only low-tension circuits will have to be opened or closed when the car is to start, reverse, or alter its speed. A still more complete solution is shown in Fig. 5, the stator circuit as well as the exciter circuit being regulated. This method of connection is less advantageously applied to high-tension motors, because the high-tension circuits generally cannot be readily altered in operation. The third diagram (Fig. 6A and 6B) shows the method of control, which, although not quite so complete as that of Fig. 5, is yet of value for small low-tension cars, and which will shortly be put in operation on a short Belgian road. The scheme of Fig. 5, with the modification represented in Fig. 7, was installed on the Stubaital line, near Innsbrück, now in operation, which is at times operated at 2,350 volts and at other times at 400 volts. The direct insertion of the excitation in the stator circuit (Fig. 2) in

Digitized by Google

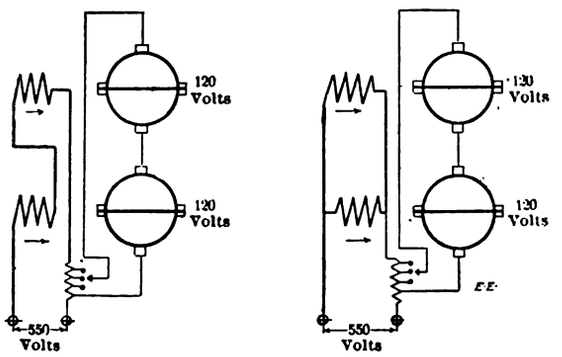
which the control is effected by ohmic or inductive resistances with the eventual application of series-parallel regulation, is possible for small cars, and hence chiefly applicable to short railway lines. In the latter case the motors can be built simply for 550 volts. Motors for 550 volts connected in this manner are already in operation, and will also run on direct-current lines (Figs. 7A and 7B).

The possibility of running an alternating-current motor with direct current is of great importance in practical application. Ordinary series commutator motors, which are built on the compensated system of Deri, can, of course, be run both on direct-current and alternating-current circuits. The voltage for the direct-current motor is one and a half to two times higher than the armature voltage with alternating current. Since, as we have shown above, the alternating-current voltage, which in our motor system can be directly applied, may be three times greater than the armature voltage, the ratio of direct-current to alternating-current voltage will be, not as in the series motor, $3 : 1\frac{1}{2}$ or $3 : 2$, but $3 : 3$ to $1\frac{1}{2}$ or 2—that is, the direct-current voltage will be about half that of the alternating-current voltage. This allows, for example, the running with direct currents with motors connected in series and with alternating current with the motors connected in series, and with alternating current with the motors connected in parallel, but in the former case at less speed. This corresponds to the case in common practice where cars which travel over interurban stretches at high speed transfer to the direct-current systems of cities, where lower speed is demanded.



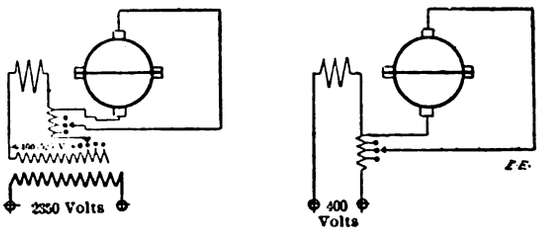
FIGS. 4 AND 5.—Diagram of Methods of Control.

There are various ways of running with the motor connected according to Fig. 1 on direct-current circuits. The method which has proved itself most practical is represented in Fig. 8. In the direction of the diameter of the exciter axis a winding is applied which counteracts and opposes the armature ampere-turns. The stator field windings then produce a magnetic field with direct current, and the exciting windings on the armature represent with direct current the working ampere windings. The field saturation in direct-current working is then somewhat greater than with alternating-current, while the density in the armature is somewhat less. These properties are extraordinarily favourable for practical operation. The auxiliary winding, *h*, is inserted only when operating with direct current. In order to make better use of the armature, the field windings of two motors can be connected in parallel in the direct-current circuit, while, in order to be able to operate at 500 to 550 volts with direct currents, the armatures can be connected in series. These conditions are represented in Fig. 9. In the alternating-current system one can operate according to the method of either Fig. 3 or Fig. 6. If operated according to plan 3, then with alternating currents the connections 2, 4, 5 are closed and 1 and 3 are open. With direct current, 1 and 3 are closed and 2, 4, and 5 are open.



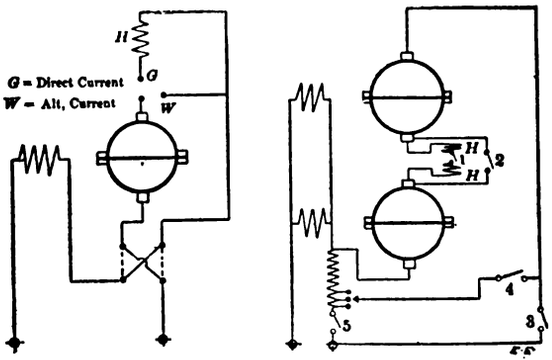
FIGS. 6A AND 6B.—Method of Control for Low Potentials.

The motor system which I have above briefly described will not be the only one in the field. I cannot, however, undertake to pass an unbiassed opinion upon the different systems possible. I can only briefly mention the reasons why, in my opinion, the alternating-current commutator motor, which has been long known in two general types—namely, the ordinary series motor and the repulsion motor—is not to be considered of equal value to the system above described. The ordinary series motor possesses, even if it is compensated, no cross field, and it has no rotary field. The short-circuit losses under the brushes do not decrease with increasing speed, and the power factor increases much slower with the speed. The maximum working voltage for which it can be built is 200 volts. When a short-circuit takes place in the field winding of the series motor, the motor becomes inoperative. Multipolar machines with series windings on the armature, if provided with the device shown in Fig. 1, can have an entire field coil short-circuited without the motor becoming inoperative. The separate field coils behave like transformers inserted in series. Any one of these can always be short-circuited, the others then receive correspondingly more voltage.



FIGS. 7A AND 7B.—Method of Control on Stubaital Line.

The repulsion motor, when contrasted with the arrangement of Fig. 1, has the disadvantage that its reversal is possible only by the application of a second field winding, or of several sets of brushes, or of reversible brushes. Its power factor is poorer, and for its control there remains only either the method of primary voltage control, the opening of short-circuits, or, finally, of brush reversal. The disadvantage of the type represented in Fig. 1, as compared with the series and repulsion motor, consists in the employment of two exciter brushes, which doubles the number of brushes in multipolar systems. These exciter brushes give rise to no difficulties with respect to short-circuit losses, as I have shown (*Elektrische Bahnen*, vol. ii., 1904). These short-circuit losses do not occur with exciter brushes. They carry, moreover, only one-third to one-fourth of the entire short-circuit current. On the other hand, the motor of Fig. 1, as compared with the compensated series motor and the repulsion motor with the double field winding, offers the constructional advantage of only one field phase, which guarantees good economy and great simplicity. In high-tension motors the increased certainty of operation in consequence of the absence of cross windings must be considered. Motors for either direct-current or alternating-current working provided with the auxiliary winding, *h*, which plays the part of the compensation winding of the compensated series motor, can, therefore, only be operated advantageously with low-tension alternating currents.



FIGS. 8 AND 9.—Motor Connections.

Digitized by Google

The results of more than a year's operation on the 6,000-volt Niederschöneweide-Spindlersfeld line, on which during a great part of the day four 100-h.p. motors haul a 160-170-ton train, and on which daily two motors handle a 100-ton train, prove that the alternating-current motor is adapted to the heaviest traffic. Moreover, the direct application of 6,000 volts to the car has been demonstrated to be entirely safe. The Stubaital line, which has been running since July 31, 1904, at 42 cycles and 2,350 volts, has introduced an advanced practice for small roads, an advance which exceeds the boldest expectations of the year 1902. At that time it seemed as though only very low frequencies could be used. In the case of many roads running in connection with existing power stations, operating with 40 to 50 cycles, the possibility of using these frequencies limits the availability of alternating-current traction. Moreover, the possibility of operating also with direct current makes the alternating-current commutator motor in a certain sense a universal motor, and places it as regards its main features far above the direct-current commutator motor, which really represents only a special case of the alternating-current commutator motor.

THE LIMITATING FACTORS OF SYNTONIC WIRELESS TELEGRAPHY.

BY J. HETTINGER.

§ 1. The "possibility of tuning" and its "practical limitation" are two well-known facts in the practice of wireless telegraphy. The first forms the seductive incitement of the optimist; the latter increases the pessimistic view of many practitioners of this new branch of electrotechnics. The present communication has the objects (1) to show a method which permits the discussion of the practical value of syntony when the resonance curves are experimentally determined, and (2) to prove that the resonance method, as utilised nowadays, may be a *partial solution* for avoiding interference, but never can it be a *general* one.

The factors which I have to consider as determining the value and limiting the possibility of syntony are the following: (*a*) The *resonance curve* of the currents and of the E.M.F.'s of the energy induced in the receiving system; (*b*) the *transmitted energy*; and (*c*) the *relative distances* between the simultaneously working stations.

§ 2. *The Resonance Curve.*—This curve, which has to be experimentally determined, represents either the E.M.F.'s at the two ends of the detector, or the currents passing through the latter, as a function of the frequencies. Its importance consists therein that it possesses a maximum at the point where the frequency of the transmitted waves coincides with the natural frequency of the receiver, and that this maximum is supposed to be just great enough as to be equal to the working minimum of the detector. Naturally, in this case, the amplitudes corresponding to the untuned frequencies would not produce any interference. There are, however, several causes which render the maintenance of the curve maximum *at* the working minimum of the detector almost impossible, and, therefore, it is obvious that the amplitudes of the curve corresponding to the untuned frequencies may also influence the detector, and make it respond. Consequently, not only the maximum of the curve, but also its shape, is of great importance for the syntonisation, the degree of immunity being, for instance, different in the four curves of Fig. 1, which I may mention for illustration.

It is not within the scope of my present communication to show how these curves depend upon the purity of the transmitted waves, the exact adjustment of the receiving circuits to a certain natural frequency, the degree of coupling, etc., and I content myself by mentioning only their main characteristics as far as they determine the degree of immunity against interference. These characteristics are (see Fig. 1): (*a*) the difference, $E_R - E_D$, whereby E_R designates the *maximum* and E_D the *minimum* amplitude of the curve, provided m_R, corresponding to E_R, is the tuned frequency, and m_D, corresponding to E_D, the frequency whereby the curve begins to become almost a parallel line to the axis of frequency; (*b*) the differential quotient, tg. $\alpha = \frac{d\,E}{d\,m}$, and (*c*) the radius of curvature, m_m at the apex of the curve.

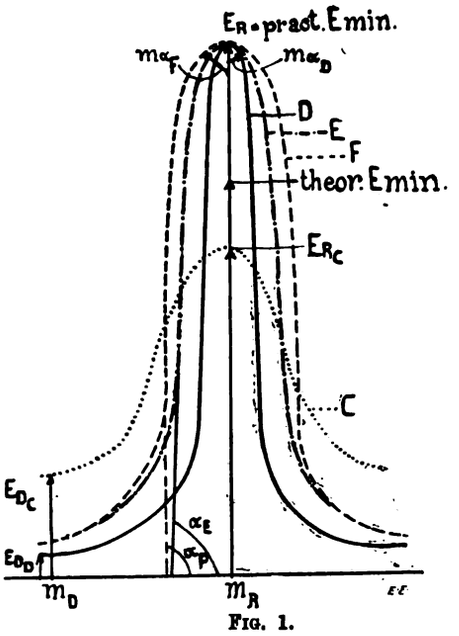


FIG. 1.

From the many hypothetical considerations which could be connected with these characteristics, I will only call special attention to the influence of the factors $\frac{L}{R}$ and $\frac{1}{R\,C}$ upon the first characteristic $E_R - E_D$. Let us, for instance, assume that the detector is controlled by the E.M.F., E_C, of a capacity, C, in parallel to it, that this capacity is in series with a resistance, R, and an inductance, L, and that the impressed E.M.F., E, is kept constant, whilst the frequencies are varied. Then, for the case of resonance—*i.e.*, when the equation $m^2\,C\,L = 1$ is fulfilled—we get (see also the vector diagram Fig. 2):

$$I = \frac{E}{R}, \quad E_L = I\,m\,L, \quad E_C = \frac{I}{m\,C},$$

and reducing R to $R_1 = \frac{R}{2}$, we get:

$$I_1 = 2\,I = \frac{E}{R_1} = \frac{2}{R}E,$$

$$E_L' = (2\,I)\,m\,L, \quad E_C = \frac{2\,I}{m\,C}.$$

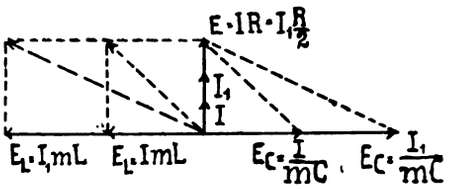

FIG. 2.

Again, doubling L, and in order not to disturb the resonance equation, reducing C to its half value, we get:

$$E = I\,R, \quad E_L = I\,m\,(2\,L), \quad E = \frac{I}{m\left(\frac{C}{2}\right)}.$$

These results mean that the resonance amplitude E_R ($= E_{C\,max.}$) is proportional to the quotients:

$$\frac{L}{R} \text{ and } \frac{1}{C\,R}.$$

Now, if the diagram corresponding to the frequency, m_D, would be considered in the same manner as has just been considered for the tuned frequency, we would find that the corresponding amplitude, E_D ($E_{min.}$), is approximately also proportional to

$$\frac{L}{R} \text{ and } \frac{1}{C\,R}$$

Digitized by Google

As, however, $E_R = E_{cmax.}$ is much greater than $E_D = E_{cmin.}$ of the resonance curve, it follows that by increasing the quotients $\frac{L}{R}$ and $\frac{1}{C R}$, say to a double value, E_R and E_D have been respectively doubled to E_{R1} and E_{D1}, and the difference $E_{R1} - E_{D1}$ has become much greater than $E_R - E_D$ This result shows that immunity may be increased by employing great quotients $\frac{L}{R}$ and $\frac{1}{C R}$ in the receiving circuits.*

§ 3. *The Transmitted Energies and the Relative Distances between the Stations.*—The received energy, P_R, depends obviously from the transmitted energy, P_T, and the distance of transmission, D. It has been experimentally proved that the received energy is inversely proportional to the square of the distance, and the supposition that it is directly proportional to the transmitted energy is also approximately exact. Consequently, we may write the equation :

$$P_R = k \frac{P_T}{D^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

or,

$$E I \cos \phi = k \frac{P_T}{D^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

E, I, and ϕ representing respectively the E M F., the current, and the lag between both in the receiving system

(*a*) For the case of resonance, we have $\phi = 0$, $\cos \phi = 1$ and consequently the equation (2) becomes :

$$E I = k \frac{P_T}{D^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Bringing now the resistance, R, in (3), we get :

$$I^2 R = k \frac{P_T}{D^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

and consequently

$$I = \frac{k}{R} \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

and as R is kept constant, we may write :

$$I = C \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (6)$$

(*b*) Assuming, farther, ϕ different from zero and the impressed E M F., E, of the equation (2) as constant, we get for each ϕ considered as constant the following equations

$$E_p = E \cos \phi_p = I_p R \quad . \quad . \quad . \quad . \quad (7)$$

$$E_p I_p = I_p^2 R = k_p \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad (4A)$$

$$I_p = \frac{k_p}{R} \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad (5A)$$

$$I_p = C_p \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (6A)$$

The equations (6) and (6A) mean that the current of the received energy is directly proportional to the mean roots of the transmitted energy and inversely proportional to the distance. The equation (6) refers to the resonance current, whilst (6A) is the general equation referring to the currents of untuned frequencies. For each $\phi = \phi_1, \phi_2, \phi_3, \ldots \phi_p$, we get the corresponding $C_1, C_2, C_3 \ldots C_p$ and $I_1, I_2 \ldots I_p$, and as, according to (7), E_p is smaller than E, the constants, C_p, and currents, I_p of the equation (6A) must also be smaller than C and I of the equation (6)

As any one of the E.M.F.'s (E, E_p. E_L, or E_C) is directly proportional to the currents, I_p, we may write for the E M.F. controlling the detector (in the above-mentioned example it was E_C considered as such an E M.F. controlling the detector), the following equation :

$$E_p = K_p \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (8)$$

With the special forms

$$E_R = K_R \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (8A)$$

for the case of resonance, and

$$E_D = K_D \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (8B)$$

for the lowest amplitude of the curve.

I call the constants $K_p = K_1, K_2, K_3 \ldots$ the *syntonical constants*, whilst K_R and K_D may be particularly called the *constant of resonance* and *absolute disonance* respectively.

The equation (8) with its two particular values (8A) and (8B) contains the three factors which determine the limits of syntony — namely, the transmitting power, P_T, the distance, D, and the constants, K, which represent the factor of the resonance curve, and which can be easily found if the latter has been experimentally determined.

I will now proceed to show how the syntonisation becomes limited, and why, consequently, the method employed nowadays cannot be considered as a general solution of the problem of interference in wireless telegraphy.

§ 4. *First Case—The transmitted energies are of equal powers of different frequencies, and at equal distances off the receiver* (see Fig. 1)—If E_R and $E_{min.}$ represent respectively the maximum amplitude of the curve and the necessary minimum at which the detector begins to respond, it is obvious that when the equation

$$E_R = E_{min.} \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

is fulfilled, the signal of untuned frequencies will produce no interference with those which have been tuned.

There are, however, two practical causes which diminish the syntonical immunity—namely : (*a*) not all the detectors are constant in their working, and, therefore, the practical $E_{min.}$ must necessarily be greater than the theoretical $E_{min.}$, otherwise it might occur that some signals will fail to be detected; and (*b*) stations working with variable distances (movable ships) or variable heights of aerials (kites, balloons) also do not allow a limited $E_{min.}$

Instead of the equation (9) we get, consequently, the inequality

$$E_R = \text{practical } E_{min.} > \text{theoretical } E_{min.} \quad . \quad (10)$$

Now it will be seen from the diagram Fig. 1 that with increasing difference between the practical and theoretical $E_{min.}$, the latter approaches E_D, and signals of other frequencies begin to interfere more and more.

The difficulty of managing the detector in such a manner as to keep the practical $E_{min.}$ closed by the theoretical $E_{min.}$, may sometimes render the avoiding of interference even almost impossible. The electrolytic and magnetic detector, as well as the bolometer, possessing a higher degree of constancy than the coherer, are more suitable for syntonic purposes, and their employment may minimise the cause (*a*) The cause (*b*) may, in the further progress of wireless telegraphy, be minimised, by the receiving station being provided with such an arrangement that E_R could be automatically adjusted to $E_{min.}$ when the distance between the working stations is variable.

§ 5 *Second Case—The transmission powers of several simultaneously working stations and their relative distances are different*—I will now consider the general case, which the practice has to deal with—viz, the syntony of simultaneously working stations irrespective of the powers of transmission and the relative distances. I assume that the resonance curve of the receiver has been experimentally determined, and in order to show the impossibility of an absolute syntony by means of the method used nowadays quite clear, I will make several very favourable suppositions.

1. I assume there is existing a syntonical system which permits a perfect fulfilment of the equation $m^2 C L = 1$ for all the receiving circuits comprised between the top of the aerial and the earthing point, so that the resonance curve is very sharp, having the character of the curve D (Fig. 1)—namely, great $E_R - E_D$, great tg. α, and small m_α

2 I suppose as realised the equation

$$E_R = \text{practical } E_{min.} = \text{theoretical } E_{min.},$$

which may be attained (*a*) by constant working detectors; (*b*) by a syntonical system whereby E_R can be adjusted to

* I have considered only the case of detectors responding on potential differences, but it is quite obvious how the case of detectors responding on currents may be also discussed.

Digitized by Google

$E_{min.}$ without disturbing the resonance obtained* ; and (*c*) by an arrangement, above referred to, whereby E_R is automatically adjusted to $E_{min.}$ when the distance varies during the working of the stations.

3. I will assume that

$$E_R - E_D = 15,$$

if E_D is considered as the unity of E M.F. This supposition is not at all interfering with the accurateness of the discussion brought in this communication, and the figure 15 may, of course, be changed for any other value which would be in accordance with the resonance curve considered; or in discussing about the further progress of the syntonisation towards a general solution, which would be proved as attainable. My supposition is deducted from the curves and data communicated by different experimenters,† although I must confess that the circumstances of their experiments are more favourable than those which the practical working stations have to deal with, and that the value of $E_R - E_D$ as deducted from these experiments are even smaller than 15.

These ideal assumptions made, let us now suppose that two pairs of stations are simultaneously working. As it is quite obvious that the currents of each transmission will flow through each of both receiving stations, let us consider how both currents will behave in the receiver.

We found above: $$E_R = K_p \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (8A)$$

and $$E_D = K_D \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (8B)$$

respectively for the case of resonance and lowest amplitude.

From $E_R - E_D = 15$ and $E_D = 1$, and from the consideration that P_T and D are supposed to be the same in (8A) and (8B), we get:

$$E_R = 16, \quad K_R = 16, \quad K_D = 1.$$

Consequently we can now write:

$$E_R = 16 \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (11)$$

and $$E_D = \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (11A)$$

whilst the numerical values of the syntonical constants, K_p, of the equation

$$E_p = K_p \frac{\sqrt{P_T}}{D} \quad . \quad . \quad . \quad . \quad . \quad (8)$$

may be easily determined from the resonance curve for each frequency intermediary between m_D and m_R.

I will now give to P_T and D of the pairs of stations under consideration certain definite values, and thus discuss by means of examples what are the effects of both transmissions upon the syntonised receiver.

Examples.—The receiving station, A, is tuned to the transmitting station, B, whilst another transmitting station, C, is simultaneously in communication with a respective receiving station.

1(*a*) Station B: transmitting power $P_T = 450$ watts.
distance from A: $D = 100$ miles.

(*b*) Station C: transmitting power $P_{T_1} = 450$ watts.
distance from A: $D_1 = 25$ miles.

We can write:

$P_T = 450$ watts = unity of power; $P_{T_1} = 1$.

$D = 100$ miles = unity of distance; $D_1 = 0{\cdot}25$ unit.

$$E_R = 16 \frac{\sqrt{1}}{1} = 16 = E_{min.}$$

$$E_D = 1 . \frac{\sqrt{1}}{0{\cdot}25} = 4.$$

As $E_D = 4$ is inferior to $E_{min.} = 16$, there are frequencies which do not produce any interference with the signals of the tuned frequency, and the limit of synteny is given by (8).

$$E_p = 16 = K_p \frac{\sqrt{1}}{0{\cdot}25}.$$

Where from $K_p = 4$.

Between the frequency for which the syntonical constant, K_p, is equal to 4 and the tuned frequency there is no possibility of avoiding interference.

2(*a*) Station B: $P_T = 450$ watts = unity of power.
$D = 100$ miles = unity of distance.

(*b*) Station C: $P_{T_1} = 1{\cdot}8$ kw. = 4 units.
$D_1 = 20$ miles = 0·2 unit.

We may write: $E_R = 16 = E_{min.}$

$$E_D = 1 . \frac{\sqrt{4}}{0{\cdot}2} = 10.$$

As $E_D = 10$ is inferior to $E_{min.} = 16$, there are frequencies which allow no interference with the tuned station, and the limit of syntony is deducted from

$$E_p = 16 = K_p \frac{\sqrt{4}}{0{\cdot}2}; \quad K_p = 10.$$

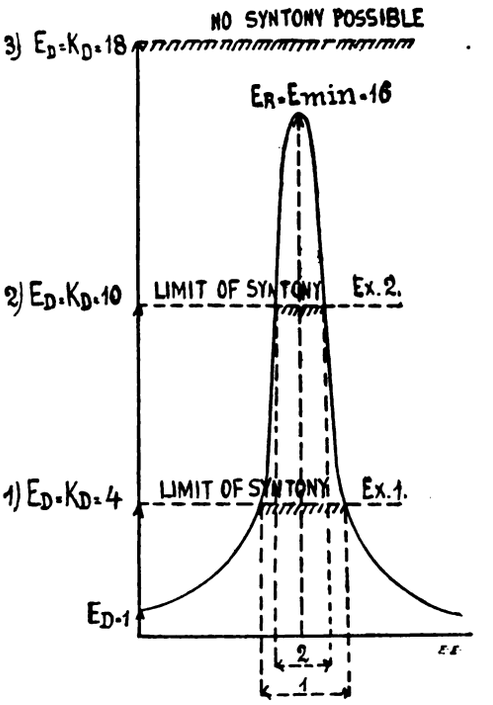

FIG. 3.

Between the tuned frequency and that one for which the syntonical constant, K_p, is equal to 10, there is no possibility of avoiding interference.

3(*a*) Station B: $P_T = 450$ watts = unity of power.
$D = 120$ miles = unity of distance.

(*b*) Station C: $P_{T_1} = 4$ kw. ~ nine units.
$D_1 = 20$ miles = 0·166 unit.
$E_R = 16 = E_{min.}$

$$E_D = \frac{\sqrt{9}}{0{\cdot}166} \sim 18.$$

As $E_D = 18$ is superior to $E_{min.} = 16$, the interference is unavoidable in a *quite absolute* manner.

I have illustrated by means of examples a series of practical cases whereby the interference is a relative or an absolute one, and I need not increase their number, as they are quite sufficient to show the true position of the problem of syntonisation, even under very favourable suppositions which I took as granted, but which practical wireless telegraphy has still to fulfil.

According to these results, I, therefore, believe that the syntonisation method as employed nowadays is only a partial, and that it never can be a general, solution of the problem of interference. The limit of syntony may, for instance, be easily found by means of the method indicated and employed in the present communication.

* An arrangement to this purpose I have described in the *Physikalische Zeitschrift*, No. 12, 1905. See also *Electrical World* of July 15, 1905.

ELECTRICITY AS A HOME COMFORT.*

BY J. D. MACKENZIE.

(Concluded from page 839.)

But if one desires that all his friends and acquaintances shall be made fully conscious of the beauty of the ceiling, we are at no loss to please his fancy and yet get away from the hackneyed method of lighting. A sketch here will indicate one method which, while not quite idealistic in that a fitting hangs in the centre of a room, is so far good in that it still hides the source of light in such a way that it can injure no one's sensibilities; and on the score of art I think you need not call the design outrageous. In this design we have a polished and silvered metal bowl, pierced and fitted with translucent mother-pearl insertions and ornamented with hanging stars. Inside the bowl is fitted one high candle-power lamp or four or five medium candle-power ones, and the total light is reflected upwards to the ceiling, from which it is again reflected downwards. This gives a soft diffused light without any very intense shadows. One other method, and that is to have an ornamental frieze moulding round the room, above which are arranged long rows of linolite or similar system, throwing every possible ray of light on to the ceiling, and so get it again reflected downwards. But you may challenge me to produce figures and argue out the point with mathematical accuracy, and though the latter part is beyond my present scope, I'll endeavour to meet your wishes as far as possible. Appended is a table giving average results both of reflection, transmission, and absorption of light by and through various media.

	Reflection. Per cent.	Transmission. Per cent.	Absorption. Per cent.
White blotting paper	82	9·2	13·8
,, cartridge	80	11·2	12·2
,, waste	80	—	—
Tracing cloth	35	54·4	15·0
,, paper	22	76	7
Newspaper	50 to 70	—	—
Yellow wall-paper	40	—	—
Dirty deal	20	—	—
Thin opal glass	—	—	15
Thick ,,	—	—	39
Strong ,,	—	—	50 to 60
Ground glass	—	—	30 to 50
Ordinary clear glass	—	—	10 to 20
Rippled glass	—	—	20 to 25
Black cloth	1·2	—	—
,, velvet	·4	—	—
Ordinary mirrors	80	—	—
V.G.	90	—	—

Now suppose that we have five 16-c.p. lamps inside a silvered bowl, such as shown, I am quite safe in assuming that 150 per cent. of the nominal candle-power is reflected upwards—*i.e.*, $\frac{150 \times 80}{100} = 120$ c.p. reaches the ceiling. If it is whitewashed and has a reflection coefficient of 80 per cent., then the total downward light is $\frac{80 \times 120}{100} = 96$ c.p. If the height of ceiling is 12ft., then the illumination on the surface of a table 3ft. will be $\frac{96}{9 \times 9} = \frac{96{\cdot}0}{81} = 1{\cdot}18$ candle-feet, and an illumination of one candle-foot is quite ample for all ordinary purposes.

Now, so far I have dealt with lighting in the abstract; let us come more to detail. Lighting by reflection is applicable to the general lighting of any room, but it may require to be supplemented owing to special requirements. In the porch or vestibule one or more lamps placed high up with reflectors are quite sufficient unless it is of large dimensions and the ceiling finished in panelled oak, say, when a combination of both methods must be adopted—viz., some lamps to throw light directly downwards and some to throw it on to the ceiling. In the hall the same remarks apply, depending on whether the ceiling is to be plaster or wainscot. The public rooms ought to be lit by reflected light entirely, but may be supplemented somewhat as follows: dining-room—one or more sockets for table lamps, so that the most of the general lighting may be switched off, and we will have a dim, very dim, downward light combined with one or two table standard lamps deeply shaded with silk shades. In this case we are yielding a point of efficiency to gain a point in artistic effect. In the dining-room we may do the same and permit one or two tall standard lamps just to please the lady of the house. In the boudoir we must. In the bedrooms generally a reading lamp must be provided, and in that case what I generally recommend is a bracket hung from the bedrail or mounted on the bedstead, and having sufficient projection and tilt to throw the light out on to a book held in a person's hand, the lamp being covered by a very deep silvered metal conical or paraboloid reflector so arranged as to concentrate the light into a beam of comparatively small area. This will give the desired effect without being sufficiently glaring to annoy. In the dressing-room I would suggest that some such thing as a strip of linolite or similar idea be fastened to either extreme side of the pier glass; it will enable the lady of the house to see to a nicety how that new gown looks, and her lord and master to shave himself, or be shaved by his valet, in absolute comfort. Now, although I am speaking in this fashion regarding portable lamps and such like for special purposes, I must not be taken as condemning these in any way. Indeed, quite the contrary, for my aim is to point out electricity as a comfort in the home, and unless every possible contingency is forestalled and provided for, and unless every individual taste is considered, and arrangements made to suit them, this result cannot be obtained. It would be quite impossible for me to deal in this paper with every contingency and every artistic taste which may have to be studied, but the foregoing may indicate how, in my opinion, these should be met, and that is to deal with the general lighting in the most effective, economical, and unobtrusive method, and then concede the other points either to necessity or artistic taste as they arise. Now, at the start of these rambling remarks I set down a few conditions which had to be looked to, but in my enthusiasm in preaching the gospel of heterodoxy I fear they are sadly in danger of being forgotten.

The first was the purpose in view that has been dealt with and amplified as far as my time will permit, so we may look for a moment at some of the others. The ease or difficulty of carrying into effect is the next point, and is one which is often missed by architects, consulting engineers, and others responsible for the design of an electrical installation. I have before now seen cases where lights were shown in position in the middle of glazed roof lights, electroliers hung from the ceiling specified where the head room was only 6ft. 6in., and so on, these cases being where an architect designed the building and a consulting engineer the lighting, and the latter had not got sufficient data for his purpose. And while on this point I cannot understand why architects should not inform electrical contractors of the details of finishing in the various rooms, etc., in a building. We have a standard height for placing brackets, switches, pushes, and so on, but that standard is by no means as unalterable as the laws of the Medes and Persians. And yet time and again we find either that our heights do not suit the dado, or the frieze, or the picture moulding, or, in fact, the hundred and one things which go to make up the finished room, and we have painfully to search the joiner's or builder's plans to discover the internal arrangements, or still more painfully drag information out of the architect. The electrical contractor is generally, and ought to be, the last contractor to leave the job, and as he has, so to speak, to add the finishing touches to the whole, why should he not be furnished from the very start with full particulars as to how the building is going to be finished? I speak with feeling on this matter, as on more than one occasion such negligence on an architect's part has been the means of spoiling good work.

The third point—viz., accessibility for repairs—has reference more to the wiring than to the fitting, and hence consideration may be deferred until that section is reached. The fourth point was the effect of each part of the design on its immediate surroundings, and is a most important one. Because, to take one instance, it would look entirely out of place to put an Art Nouveau fitting into an old-world setting, and it looks quite as incongruous to my eyes to fit up a modernised drawing-room or dining-room with Louis candle brackets, and both of these—with many other

* Paper read before a Glasgow Engineering Society.

Digitized by Google

variations on the same general lines—are done daily by people who aspire to gain credit for their artistic taste. Here it is that, if the room is lit by reflected light, one may give full rein to their artistic fancy. And just a case in point. I know of one entrance hall which has been beautifully designed and executed in rigid Moorish art, and the attempt was made to light that by means of lamps enclosed in handsome lanterns of pierced metal work of strictly Moorish design, and the result was, as might be expected, a ghastly failure. The gentleman who owns the house on looking about found a quasi-Moorish design, as now shown on the screen, and fitted up the hall with those. Of course, better light has been obtained, but the strictness of the art has been sacrificed, and the lighting, owing to this heavily obscured glass globe, is very inefficient. Had reflected lighting been tried, the old lanterns might have been retained with a lamp inside them for artistic effect, and the whole general lighting got quite independently and invisibly.

The fifth point—the general effect of the whole arrangement—is a difficult point to elucidate. What I mean by it is that sometimes in looking over a finished job one gets the impression that there has been no design—that, in fact, things have just happened. You know it has been said of milestones in the Highlands, that the men who set them up just carried them until they were tired and then laid down without any reference to the number of yards or feet. Something similar seems to be the case in many installations—everything seems haphazard, without rule or apparent reason, and the only way to obviate this is to study each installation separately in all its bearings and have a uniformity of purpose running through the whole scheme. I may deal with this point again under "Wiring."

So far I have dealt with the outward manifestations of electrical work, but it is quite evident that without preliminary labour we could not obtain these results, and so we must consider electric wiring and its accessories. And first as to systems of wiring. I am repeatedly asked what is the best system of wiring for all purposes, and just as repeatedly I answer, "There is none." Among all the varied and various systems there are many good ones, there are some not so good ones; but there is none which can honestly be called universally the best, just as there is none which can be in the same way termed the worst. And the reason for this is not very far to seek, for electric wiring has to be installed under such varying conditions that it is manifestly impossible that any one system should be universally applicable, and here, as well as in the matter of fittings and finishing, should each installation be considered strictly on its merits in all its bearings. Now, I know that architects are most intelligent men, brimful of knowledge on any topic under the sun, but I humbly venture to suggest that they are not so qualified to give such close and careful consideration to this matter of electrical wiring as an electrical engineer, and that even with their most careful consideration they are more liable to come to a wrong conclusion. And as the first essential of a "comfortable" installation is the quality of the wiring, I really think that architects should not arrogate to themselves the right of dictatorship on matters electrical. I could regale you for hours with errors of specification and in technical detail; and not only so, but it is just as difficult for an architect to supervise the work while in progress and to discriminate whether or not the specified material is being installed. If, for example, solid-drawn screwed tubing is specified, can he or his inspector—clever men though they be, the most of them—tell the difference between that and welded tube; if "ring" cable is specified, can he say decisively that the material being installed is of German origin; and, to come to an even more simple matter, can he tell whether the ceiling rose he is looking at has English or German porcelain? Now all these things, and many, many more, produce the difference very often between a good job and a bad one, and so I really think that architects would do well to remember that they are not electrical experts, and obtain the assistance of one to superintend the electrical portion of their work. Now in this connection I must point out that the honest contractor will do his work honestly and up to specification, aye, and even beyond specification when he detects flaws in it; but there are others. The type of man I have in my mind to-night, and whose claims I wish to impress on this craftsmen's society, is the electrical craftsman; the man who scorns such questionable methods of increasing the £ s. d. return from his work, and who endeavours to do good work for good work's sake. But there are others, men whose artistic soul can only distinguish three colours—yellow, grey, and bronze—as exemplified in sovereigns, shillings, and pence—and whose work never reaches above mediocrity. Now the principal systems in use for electric wiring are as follows, not in order of merit: (*a*) wood casing; (*b*) slip-joint tubing; (*c*) screwed steel tubing; (*d*) lead-sheathed wires; (*e*) wires carried on insulators—this latter system not being applicable to internal wiring.

Wood Casing.—This is, with the exception of wires carried on insulators, the oldest system we have, and is a most satisfactory system in many cases. Where there is little or no possibility of moisture getting at the wiring, and where the work may be exposed, there is really nothing to beat a good wood-casing job provided that the workmanship has been well carried out; and this word "workmanship," which stares us so hard in every specification and schedule that we handle, brings me back to the question of the best system. A good workman can make a satisfactory job of the worst system, and a bad workman a bad job of the best possible system—given in each case that other conditions are suitable. Hence the utter impossibility of getting good work done at ridiculously low prices. It is quite absurd to imagine that if the highest offer for a contract is, say, £1,500, and the medium offers £1,000 to £1,200, that any mortal man can do the same job and give the same material and workmanship for £543. This is a sample of actually quoted prices, and tells its own tale. But to continue my remarks on wood casing. If the work is well planned, and the casing erected by joiners who have an ideal system for dry situations, concisely put, the advantages are: (1) ease of erection; (2) the wires are separated, and to a certain extent insulated throughout their entire length; (3) the wiring is very readily accessible; and the disadvantages urged against the system are: (1) that the casing does not give much protection against nails; (2) it is not suitable for damp situations; (3) it is not fireproof. In my opinion objection No. 1 is overestimated, because very few people nowadays will attempt to drive nails through electric wires, and objection No. 3 can be overcome by using casing impregnated with fireproofing compounds. Some people urge ugliness as an objection to wood casing, but this is hardly correct, as it is quite possible to get casing moulded in all manner of styles and to use it decoratively as for panelling, say.

Slip-Joint Tubing.—Now, to me this system is an abomination; it simply stinks in my nostrils. Nevertheless, it is by no means impossible to make a good job with it, and hence I do not intend to impress you with the idea that it is the worst system. Do not misunderstand me. But it is a system of the slap-up order which lends itself so easily to unskilled labour that the tendency is to use such labour, with the result that it is so easy to make an inferior job, and hence I consider it best to dispense with the temptation to do so altogether. The principal advantages claimed for it are: (1) ease of erection: (2) cheapness of first cost; (3) it is fireproof. And the principal disadvantages are: (1) thinness of conduit, rendering it easily pierceable by nails and easily eaten away by the acid commonly found in ordinary plaster; (2) difficulty of securing through metallic continuity. I have here samples of a system worked out by Messrs. Rawlings Bros., Limited, of London, which is a variant of the slip-joint system, only they use tinned brass tube instead of enamelled steel. The system, which was originally got out to meet the requirements of a London firm of consulting engineers, can be used either as a double-wire system or for concentric wiring with only one wire inside the tube, and having the tube itself for a return. Of course, this concentric system can only be used for private plant work. In this system the advantage of the slip-joint system is maintained in the ease of erection and metallic continuity, and more skilled labour is ensured by the fact that all joints in the tubing are soldered by means of a blow-lamp flame.

Digitized by Google

In a note which I received from Mr. Rawlings yesterday he says: "You will note that I have had the switch coupled up in a manner which I personally favour—that is, to bring both positive and negative to the switch and distribute from the switch point, and no other point. This method simplifies planning, and, in my opinion, surpasses externally the general system of wiring. Every joint in the system is of the slip-socket type, enabling bends to be easily erected, and the soldering is carried out with a blow-pipe, making a perfectly watertight conduit system. Tinned brass tube has not, so far as I can learn, ever failed either in or outside plaster work, as the one metal appears to save the other from decay. The thinness of the tube tends to reduce condensation, and in practice such a thing is unknown. Generally speaking, the price compares favourably with a steel tube screwed system. I have every confidence in this method of conduit, and consider that it will outstrip most of the others, owing to its lightness and its ease of erection due to its small size, and for the other points to which I referred." Personally, I have had no experience of the system, but considered, as it would probably be new to most of those present, that it was worth while mentioning. The system looks neat, and can be made thoroughly watertight. All switches and wall sockets are flush, and everything is metallic throughout. The only drawback I can see is the thinness of the tube and its liability to damage from nails.

Screwed Steel Tubing.—Here we can have any amount of diversity in the way of thickness, quality, etc., such as gas barrel, enamelled and unenamelled conduits, both solid drawn and welded, giving a wide range of choice. In this system we have the strongest mechanical arrangement possible, and when the conduit is free from any roughness inside likely to damage the wire when being drawn in, there are very few serious objections to urge against it for average work. The advantages are: (1) excellent mechanical protection; (2) excellent electrical continuity of sheathing; (3) if properly erected, lends itself admirably to a draw-in system. The disadvantages are: (1) the want of flexibility of the system rendering it difficult to instal in finished buildings, and making it almost impossible to make additions or alterations on the lighting; (2) in damp situations there is a tendency for moisture to condense outside the tubes.

Lead covered Wire.—Here we have wires possessing their own metallic sheathing as they come from the cable works, but the sheathing is of soft metal. The principal advantages are: (1) ease of installation; (2) sheathing is waterproof; (3) difficulty of making joints compels the use of a loop in system; (4) when properly bonded the sheathing is electrically continuous. The disadvantages urged against the system are: (1) softness of sheathing giving no mechanical protection; (2) risk of damage due to carelessness of workmen.

WEDNESBURY CORPORATION ELECTRICITY DISTRIBUTION UNDERTAKING.

The Wednesbury Corporation obtained a provisional order in 1899, an agreement having been previously entered into with the Midland Electric Power Company. In accordance with this agreement, the Corporation did not oppose the company's application for a provisional order to supply within the borough on the understanding that, in the event of the Corporation also applying subsequently for a provisional order, the company would not offer opposition, the objects of the power company being rather to supply in bulk to large consumers, such as mines, extensive engineering and other works, than to distribute electricity in detail to private consumers. The arrangement now is that the Corporation supplies electricity in detail to all consumers in Wednesbury, the company supplying the Corporation only in bulk.

The electricity is generated on the two-phase system at a pressure of 7,000 volts at the power company's station at Ocker Hill. It is then transmitted to the company's sub-station in Wednesbury, where it is transformed down to a pressure of 2,700 volts and again to 200 volts. The supply is delivered at the company's sub-station to the Corporation's "receiving mains" on the two-phase system at a pressure of 200 volts. The Corporation's sub-station contains transforming plant to convert from two-phase to continuous current. After conversion, continuous current is supplied by feeding mains laid from the Corporation's sub-station to five feeding points which supply the distributing network of mains laid in about 3½ miles of the principal streets, which are now in the form of a triangle in the centre of the borough, and from each corner radiate the main roads. Thus the Corporation's mains are complete in themselves, and are so arranged that at any future date they may be supplied from separate works should that become advisable later, whereas the two-phase supply would not be economical from a separate plant owing to the nature of the borough and the demand in Wednesbury. It may here be mentioned that both the two-phase and continuous-current systems of distribution were very carefully considered, and, after taking all circumstances into consideration, the latter was decided upon notwithstanding the additional expenditure necessitated by the transforming plant, so that full advantage could be taken of the maximum demand system of charges (for the supply in bulk) and also to give the most convenient form of supply to the consumers.

A portion of the Corporation's land has been utilised as the site of the sub-station. The buildings consist of the following: generator room and switch gallery, accumulator room, workshop, office, test-room, and stores. The three last-named are connected to the main building by a corridor. The buildings are arranged so that they may be easily extended; in the case of the office, etc., building provision has been made so that another floor can be added at any time with little or no alteration. The contractor for the main office, etc., buildings was Mr. F. J. Smith, of Wednesbury.

The transforming plant includes two motor-generators manufactured by the Phœnix Dynamo Manufacturing Company, Limited, of Bradford. These each consist of a two-phase induction motor direct coupled to a continuous-current generator capable of delivering a current of 300 amperes at a pressure of 250 volts. There are two special pillars which contain the starting gear; these pillars are fixed adjoining the machines.

The battery of accumulators consists of 117 cells, each capable of delivering 325 amperes for three hours. The containing cases are constructed entirely of lead, the crate being in the form of an antimony ⊥ section frame burnt together and lined with 6lb. sheet lead at sides, and 10lb. lead at bottom, and supported on a slate base. Each cell has 27 plates, the positive plates being of the Planté type and the negative of the pasted type. The cells have been supplied and erected on heavy pitch-pine stands by the British Accumulator Company, Limited, of Westminster. There is a charge and discharge booster of the Highfield type manufactured by the British Westinghouse Company, Limited. The booster dynamo is capable of a maximum back boost of 75 volts during charging of the battery, and is capable of keeping the pressure practically constant on charge or discharge automatically within a limit of 30 volts difference of battery and line voltage, under all conditions of load (up to 325 amperes) and battery voltage. The exciter is direct coupled to the booster, and the machine may be driven by either a continuous-current motor of 30 h.p. or a two phase motor of similar size. The continuous-current motor is connected to the booster through a clutch, and the two-phase motor is similarly connected to the continuous-current machine. These clutches enable the following arrangements of use: (1) two-phase motor driving continuous-current machine as a dynamo, booster disconnected; (2) two-phase machine driving booster through continuous-current shaft, the latter idle; (3) the same as (2), but continuous-current machine being run as a generator as well; and (4) continuous-current machine only driving booster. In addition, a portable "milking" booster has been provided, consisting of a 200 volt two-phase motor coupled direct to a shunt dynamo capable of delivering 150 amperes at six volts. This plant is mounted on a truck for convenience in moving about the accumulator room to enable one or two cells to be charged as required.

Digitized by Google

The switchboard, which consists almost entirely of metal and marble, is arranged in a "bay" form, the central portion being reserved for the two-phase feeder gear and the continuous-current main ammeter, voltmeter, and time-piece. On the left side of the bay the continuous-current feeder panels are fixed, and on the right the machine panels. The switch gallery is raised about 1ft. from the floor level, and contains also the starting pillar of the booster. Behind the switchboard ample space has been allowed, which forms practically a separate small room, and contains, in addition to the switchboard connections, the main two-phase meters and the main continuous-current meter. The switchboard is arranged to control the following: duplicate two-phase "receiving" mains, three motors (two main and one booster), a spare panel being allowed for an additional machine, five continuous-current feeding cables, and two spare feeder panels, two main dynamos and two boosters on the continuous-current side, one spare panel being allowed for each. A system of subways leads from the switchboard to the machines, battery, etc., and to the street, for conveying the connecting cables. The switchboard was manufactured and erected by Mr. W. Sanders, of Wednesbury, the instruments being of the permanent magnet edgewise and sector types, and mostly by Nalder Bros. and Thompson.

The mains consist of two-phase twin concentric ·3, ·3, and ·45 square inch lead-covered "receiving" cables (connecting the Corporation's sub-station with the power company's sub-station), concentric lead-covered, continuous-current feeding cables, and single lead-covered cables for distributing mains. The distribution is carried out on the two wire system, the pressure of supply being 230 volts. All cables are laid on the solid system, being supported on wooden bridges in wooden troughs, filled in solid with bitumen and protected by hard-burnt tiles. Generally, where there are tramway lines and in important streets, the distributing mains are laid on both sides of the roadway under the footpaths, but in the less important streets on one side of the road only. The cables were manufactured and laid by Messrs. W. T. Glover and Co, Limited, and are of their well-known diatrine paper-insulated type.

The contract for meters, etc., was divided, the electrolytic and motor meters, maximum demand indicators, as well as the house service fuses and fuse boards, having been supplied by the Reason Manufacturing Company, Limited, and the prepayment meters by the British Thomson-Houston Company. The charges for the supply are as follows: lighting, 6d. and 2d. per unit on the maximum demand (one-hour) system; power, 3d. and 1½d. per unit, or a flat rate of 1½d. per unit in the daytime and 3d. during lighting hours.

An important point in connection with a distribution undertaking such as this is that there is no risk of excessive cost of production in the early years. The charge for electric power in bulk to the Corporation is 3d. for the first hour of maximum demand for each day and ·825d. per unit for all further supply. The losses as regards inefficiency of transformation and losses in mains appear principally in units at the lower charge, and the losses in the accumulators are entirely low-rate units. The supply of electricity to each individual consumer is on the maximum demand system, yet, owing to the diversity of the time of the maximum load, the total maximum load of the Corporation is less than the sum of each individual consumer's maximum demand during each quarter. Further, as the accumulators reduce the Corporation's maximum demand on the power company, the load is more even, or, in other words, under the system of working, if the maximum load on the Corporation's sub-station is, say, 150 kw., the demand by the Corporation on the company need only be 75 kw., so again there is a large transfer of units from the 3d. to the ·825d. rate, and the units lost in the battery are entirely at the low rate, as before mentioned. Further, in an undertaking of this nature the increase in the Corporation's capital charges as the load increases will not be heavy.

A few figures as to the results of 18 months' working may be of interest. The consumers number about 90, and the connections have reached the equivalent of 5,258 8-c.p. lamps, including 28 h.p. in motors; also 596 lamps of 8 c.p. equivalent have been applied for in addition, but have not so far been connected. Various extensions of the mains have been carried out by the staff to cope with the demand which has arisen. A noticeable point has been the even pressure which has been maintained, rendering the use of Nernst lamps very satisfactory. It would not otherwise have been possible to compete successfully with incandescent gas lighting in the borough.

The technical negotiations with the power company were carried out by Mr. F. J. Warden-Stevens, A.M.I.M.E., A.M.I.E.E, of Westminster, who has acted as consulting engineer to the Corporation, and under his supervision the undertaking has been completed and operated. Mr. W. Fennell acted as assistant to the consulting engineer, and Mr. T. H. M. Swinburne as clerk of works. The undertaking has been carried on for 18 months under the instructions of the consulting engineer, and the position of resident engineer is held by Mr. W. Fennell. It is to be noted that electricity has been introduced into the following public buildings town hall, municipal offices, art gallery, public library, and public baths; the arrangements having been planned and the work supervised by the consulting engineer.

YARMOUTH ELECTRICITY ACCOUNTS.

The accounts of the Great Yarmouth electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £79,466. Appended are abstracts of the revenue account, balance-sheet, etc.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
To generation of electricity	6,014	7	6
Distribution of electricity	36	13	8
Attending and repairs to public lamps	485	13	10
Rates and taxes	712	6	0

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

Post Free, Payable in Advance.)

CHRISTMAS, 1905.

We wish all our readers a happy Christmas, and trust that they will spend the time profitably. We expect that the few days' holiday will be devoted by the largest percentage of electrical engineers in this country to reading the accumulation of papers communicated to the Institution of Electrical Engineers and its various local sections. There is an old proverb which says, "You can take a horse to the water, but you cannot make him drink." We thought that this was strictly applicable to electrical engineers until we were recently supplied with an almanac by a well-known cable firm. In this firm's rules for jointing electric cable prominence is given to the first requisite, "See the jointer is well supplied with beer." The correct conclusion may be that the jointer is not an electrical engineer, or, perhaps, this is the exception which proves the truth of the above proverb as applied to our profession. In case any of our readers, after absorbing the literature above referred to, should feel too elated with the magnitude of their profession and the scientific accuracy of its members, we reproduce the following extract from the *Daily Mirror* for Oct. 4 last: "Either electricity is an exact business or it is not. Perhaps the fact is that electricity, like the white man, is 'mighty uncertain,' and needs more expert management than it gets. We wish with as much fervour as we possess that there were more certainty and less guesswork about these ohms and volts. It may be that some of the electric experts are not experts at all, but adroitly disguised farm labourers, who have taken a few weeks' course of alleged training, and adopted what looks like an easy, gentlemanly career. Offhand, from one's personal experience of the man in one's own office who keeps the electric bells in disorder and wrongly diagnoses the disease of the telephone, the conclusion is reached that there must be a great famine of men who really understand electricity. Electricity in many cases is being supplanted by gas. Electricity should drive gas out of use, one would think, if it were managed by the right persons. All this from the standpoint of the consumer. It is likely that the fault lies in the fact that there are not enough Edisons to go round, and that it takes an Edison to cope with the tremendous problem of guaranteeing that our electric bell will ring when we push the button. Ours is the lay mind, and we apologise if through ignorance we hurt the feelings of anyone, but it has always seemed to us that the electrical industry is handicapped by the enormous number of men who spend their time in pottering about with wires, doing gimcrack work improperly, and then redoing it the next day with a different sort of incorrectness." It is so unusual to have the editor of a daily paper apologising for his ignorance, that we feel the above strictures should be taken with absolute silence. Our readers will doubtless ponder over the fact that while "there must be a great famine of men who really understand electricity," the demand caused by this famine should not raise the remuneration offered to the few remaining experts.

FORTHCOMING EVENTS

Friday, Dec. 22.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

BRAZING CAST IRON.

SIR,—I notice in your issue of Dec. 15 the note from "J. E. H., Pretoria," and I have pleasure to convey to this gentleman through your valued medium as much information as I possess.

I am informed on good authority that the problem of mending cast iron has only recently been satisfactorily solved, and a syndicate is shortly to be registered who will work the new process. By this process brazing is entirely done away with, the repair to the cast iron being made with cast iron. I happen to have seen some repairs which have been made, and it was quite impossible to tell the repaired portion from the article itself, and on these being tested for strength it was absolutely proved that the joint was even stronger in many instances than a similar piece which had not been broken, and no shrinkage or change of form even to the slightest degree had occurred. I am not able to give any detail of the process, as I do not know it; all I know is that it is the outcome of many years of experimenting, and, so far as I could see, it will entirely revolutionise the position which cast iron takes in engineering, as the trouble connected with its brittleness is entirely overcome. I am informed that this syndicate will be prepared to grant licenses for its process very shortly.

I should be very pleased to communicate with your correspondent if he writes me, and assist him in any way in my power. I enclose my card.—Yours, etc.,

A READER OF "THE ELECTRICAL ENGINEER."

MR. PATCHELL'S INSTITUTION PAPER.

SIR,—In the *Electrician* (vol. 54, p. 573) Mr. J. S. Highfield wrote a short article dealing with certain troubles that had been met with about that time in the working of his 3,000-kw. 11,000-volt steam alternators at Willesden, for which my company were the contractors. Previous to such publication Mr. Highfield courteously communicated with the parties concerned in order to ascertain if they had objections to the publicity that would be thus given to the matter, and in view of the scientific interest attached to the questions involved, no objections whatever were raised at the time.

I do not propose to deal here with the causes that led to the troubles, or with the nature of the same, beyond remarking that there never was any doubt with regard to these points. Moreover, it soon transpired that many other makers in this country, the States, and on the Continent had met with the same phenomena from time to time and to a greater or less extent. But it is to be particularly noted that in the above-mentioned article of Mr. Highfield's it was specially pointed out that all the materials used in the construction of the armature were the best of their respective kinds, and I may add that Mr. Highfield's statement in this respect was based upon the reports of the independent specialists to whom the question of the quality of the materials employed had been specifically submitted. The reports made by these gentlemen, based upon their analyses and examinations, were absolutely conclusive on the point, and it became perfectly clear that the troubles were due to other causes and conditions, which those interested will find set forth in Mr. Highfield's article.

Notwithstanding the fact that nearly £60,000 worth of plant was involved, regarding which even the shortest stoppage meant inconvenience and loss, the Metropolitan Company and its engineering staff (recognising that the troubles were due to exceptional causes which could not have been foreseen) extended their sympathy and practical help to the contractors from the first to the last, and after the difficulties had been overcome and the contract closed an amount of £4,400 was awarded to the contractors as a bonus in respect to steam consumption, efficiency, and reduced heating.

The publication of Mr. Highfield's article naturally gave wide publicity to the matter, and, as a result, much comment has been made in many quarters in regard to the same. Throughout, and from everyone—particularly from competitors—I have received much sympathy and evidences of goodwill, and in some cases considerable help, in the shape of data and particulars of similar insulation troubles with other high-pressure plants.

It remains for Mr. W. H. Patchell, in his recent Institution paper, to be the first, as far as I know, to bring up and treat this matter in an altogether different manner. Referring to Mr. Highfield's discovery of nitric acid in the windings of the Willesden alternators, he says: "It appears to the author, therefore, that probably the acid is due to impurity of the insulating materials rather than the destruction of pure material by ozone."

In other words, Mr. Patchell, knowing little or nothing of the facts of the case, and in face of Mr. Highfield's explicit statement to the contrary, goes out of his way to do my company and the manufacturer of the alternators a grave injury by deliberately making the wholly incorrect assertion that the troubles were due to the use of *bad materials*.

I feel compelled in the interests of the manufacturers of the alternators to protest against Mr. Patchell's action, and in doing so have little doubt but that I shall have the support of all those who like to see fair play. It may be that Mr. Patchell, when making the comments in question, did not realise that he was doing an injustice and an injury to others, and if this was the case I have no doubt that he will think it well to withdraw or amend the statements referred to above.—Yours, etc., A. C. EBORALL.

[We understand that Mr. Highfield has already contradicted Mr. Patchell's statement in the discussion on the paper. Mr. Patchell will, therefore, have to refer to the matter in his reply next month.—ED. *E.E.*]

THE PRODUCTION OF A DISINFECTANT (HYPOCHLORITE OF SODIUM) BY ELECTROLYSIS.

BY C. V. BIGGS.

It is possible that, even in scientific circles, not everyone is aware that we have, in a solution of chloride of sodium treated electrically so as to convert a certain proportion of the salt into hypochlorite, a deodoriser of considerable value, and a disinfectant and even steriliser of approved quality. Various attempts have been made to bring this substance within the scope of commercial applicability, but hitherto with but meagre success. This may be attributed in some cases to the use of too weak a solution tending to bring the substance into disrepute, to difficulties in its production, or to its lack of stability, or the quality of keeping its strength. A recent paper by Mr. Pollard Digby, read before the Faraday Society, deals with this latter most important question. From this it is apparent that, after the solution has reached a certain strength, the deterioration which goes on in the same solution is so considerable that a large proportion of the energy used in conversion is consumed merely to supply the waste—*i.e.*, to keep the solution at a constant strength in the tank. Temperature of the solution during working is also of vital importance. It will thus be seen that it is necessary to maintain a low resistance of the liquid by increasing the quantity of sodium chloride in the tank, otherwise the action of the current at an increased voltage will tend to be a heating one. These factors, depreciation, temperature, and efficiency, exercise the control over the manufacture of the liquid, as at present practised. Practical experiment goes to show that for commercial purposes a solution of 2 grm. or 3 grm. per litre is about what is to be aimed at. Prof. Kanthack's report on the Maidenhead experiments (1898) gives sufficient evidence of the sterilising properties of such a solution when used in the proportion of 2 gallons per 1,000 gallons of sewage effluent, whereas we have Sir H. Roscoe's report on the Hermite system at Guildford to show that a solution of 1 grm. per litre is liable to rapid deterioration, and has no value as a steriliser, though it constitutes an excellent deodoriser. To produce a solution of this strength an expenditure in energy of some 10 kilo-

Digitized by Google

watt-hours per 1 000 litres will be needed, according to the data at present available.

An important feature of the case, however, is brought forward by Mr. Digby's paper, before alluded to, which is that at the end of a run, or period of conversion, a large proportion of the salt in the tank still remains in its original condition, and must, therefore, be taken into account in any calculations of efficiency. Quotation is made from a collection of records of experiments made by Herr Victor Engelhardt, and from these a table has been compiled relating to this point. This table gives four instances of runs to attain solutions of from 3 grm. to 15 grm. per litre of available chlorine, the voltage being kept constant at 5·5, and salt being added to keep the solution in a good state of conductivity. The highest percentage of salt converted shown on this table is 13·6, which was attained for an 8·2 grm per litre strength. In fact, the average conversion appears to be about 10 per cent. of the total quantity of NaCl in the solution. As this residuum (about 90 per cent.) of salt will probably be waste on account of the action of the water, we have here a very marked source of inefficiency in the production of the hypochlorite solution. It appears, however, to be difficult to carry on the process, as at present practised, without this large preponderance of salt present in the solution which cannot be converted.

The question of the manufacture of this fluid would seem to depend, not so much on actual cheapness of the process (we have evidence from Dr. Alexander's report for Poplar and Dr. Robinson's for Maidenhead, that the liquid can be produced for about 1d. per gallon), but on the possibility of producing a really stable solution. From a curve given in Mr. Digby's paper it is evident that the higher in grammes per litre of available chlorine the solution can be made to go, consistent with the time available, the better will be the lasting qualities of the liquid. For instance, a solution of 6·5 grm. per litre had, in 43 hours, deteriorated to 5·2 grm. per litre, while a solution of 8·8 only dropped to 8·2 In another diagram it is shown that the effect of deterioration of the solution under conversion is appreciable when the strength has risen to 4·18 grm. per litre, and that at a strength of 8 grm. per litre the yield per kilowatt-hour is adversely influenced by over 60 per cent. It would appear from this and other data on the subject that after the solution has been worked up to about 4 grm. per gallon strength, the resistance of the liquid rising causes the process to become inefficient in conversion of salt, or in consumption of power, or both.

As the interest in this steriliser appears to be reviving at the present time, and the load for the purpose of electrolysing would be a very welcome one to any generating station in whose neighbourhood an electrolysing plant might be installed, it is to be hoped that the difficulties in the matter of stability and waste of salt may be so far overcome as to render the process a commercially successful one.

BRIGHTON ELECTRICITY UNDERTAKING.

Local Government Board Inquiry into an Application for a Loan.

A great deal of public interest was centred upon the proceedings of the Local Government Board's inquiry into the application of the Town Council for sanction to borrow £38,500 for electricity purposes and £5 909 for the purchase of the Star Foundry site and the erection thereon of buildings in connection with their electricity undertaking The inquiry, to which we called attention last week, was opened on the 12th inst., and lasted two days. It was conducted by Mr. H R Hooper, M A, M.I.C.E The town clerk (Mr. Hugo Talbot) appeared in support of the application on behalf of the Corporation, and Mr. Elvy Robb represented a committee of ratepayers who opposed the application of £5,909, while Mr. J F. Blacker watched the proceedings on behalf of the Ratepayers' Federation. The town clerk at the outset furnished the inspector with details of the borough's indebtedness, which was £2,607,232. included in that being £482,798 for electricity and £268,286 for tramways. Turning to the present application, he explained that the period of repayment asked for in respect of the £38 500 was 25 years, and for the £5,909 40 years. With regard to the former amount, he was instructed to withdraw an item for some of the proposed fitting mains, which would reduce the sum by £2 650. The balance, £35,850, was made up in this way: 900 house service connections at £10 each, £9,000; one new feeder, £2,000; 1 000 meters at £4 each, £4,000; motors for hiring purposes, £4,000 These motors were purchased by the Corporation and let out for the convenience of customers, and also as additional means of encouraging the consumption of electricity. The revenue produced was amply sufficient to cover all the charges, and also to derive profit on that part of the business. Additions to the switchboard and accessories would cost £1,350. The 900 house services represented the system of requirements for the next three years, and was based upon the actual demand during the four preceding years, that average being 344 a year. Much time was then spent in discussing the methods of keeping accounts relating to loans, the inspector desiring to be informed whether it had not been the practice in seeking sanction for a loan for a specific purpose to apply it to another purpose The town clerk replied that such a question had never been raised during the 15 years of the undertaking, and he was not, therefore, prepared to answer it at once, but he contended that so long as the amount sanctioned was not exceeded the matter was immaterial. The first witness called was the engineer, Mr. John Christie, who explained in detail how the estimates had been made up, and upon each item he was carefully examined by the inspector. Regarding the cost of services at £10 each plus £4 each for the meter, he attributed the increased cost to the fact that the Corporation were now taking a class of consumer whose house had a long front garden, and therefore the cost of laying on the service to these houses was higher. But a further examination elicited a statement that the cost had been overestimated, and this was eventually reduced to £6. 10s. Mr. Christie admitted that he had not made comparisons with other towns in England, and was, therefore, not in a position to say whether in Brighton they were doing work cheaper or whether it was costing them more. Other towns, he said, had different conditions, but he averred that in Brighton the work was being done economically. Mr. Christie was then examined at great length on the question of £4,000 for meters. Here, again, the established precedent was departed from, inasmuch as the inspector entered into details upon which he could not receive enlightenment because the necessary information had not been prepared. It was stated that during the last 14 years £37 800 had been expended for meters and only £1,000 had been written off. Mr. Christie could not say whether they had exceeded the amount sanctioned, as it occurred before his time, but on the second day of the inquiry it was brought to light that the sum had been exceeded by £2,500. The town clerk promised to advise the Council to repay the money out of the reserve fund. With regard to the £5 909 for the Star Foundry site, the town clerk urged that there was a necessity for the additional accommodation, which would not be a burden on the undertaking. The old North-road station would be retained as a generating station. Mr. Christie explained that the steam plant would be retained in order to take the "load" during the three darkest months. The Southwick station when in full work would supply two-thirds of the maximum demand, and the North-road plant would be run to meet the "peak," which would be more economical than scrapping the whole of the existing plant at North-road and buying new plant to instal at Southwick. For nine months in the year the North-road station would be practically closed down as a generating station. During the other three months they would run on one shift of men. The inspector thought that the steam-engines at the station were not up to date, and the station would have to be kept open because it would not pay the Corporation to scrap the machinery.

The examination of the chairman of the Lighting Committee, Mr. Butt-Thompson, related chiefly to the allocation of loans and methods of keeping accounts. Mr. Arthur

Digitized by Google

Wright, consulting engineer to the Corporation, stated that he recommended the expenditure of £437,000 on the new works, and so far they had expended £330,000 including what they had rendered themselves liable to. At present there were three foundations out of nine occupied by the 5,600 kw. of engines. The maximum that could be put into the station was nine times 1,800—that is, about 16,000 kw.—and the maximum load last Christmas was only about 5,000. Asked by the inspector when he expected the station to be filled with plant, he answered that it would depend on the development of the business. He denied the suggestion of Mr. Robb that the station was designed solely to supply the needs of the neighbouring districts. A great deal of the cross-examination of witnesses by the solicitors for the opposing parties was altogether outside the scope of the inquiry, and the proceedings were on that account greatly protracted. Much of the criticism was based on surmise, and although it seemed formidable, there was in point of fact nothing relevant in it which had not previously been touched upon by the inspector, whose searching investigations revealed several points which deserve attention. Mr. Elvy Robb contributed much amusement to the inquiry, which it is doubtful if even this was worth the time wasted by him and by Mr. Blacker.

THE COMMERCIAL TESTING OF SMALL MOTORS UP TO 15 B.H.P.*

BY THOMAS CARTER, A.M.I.E.E.

(Concluded from page 842.)

As a rule, however, the power-house does not give the exact voltage required for 3, and then 1 and 2 are also belted together to run as a motor-generator set. The armature of 1 is coupled to the power-house, while 2 must have an armature which will generate the volts required for 3. Then 2 and 3 are electrically coupled together, and the shunt of 3 is in this case excited from T_3. The process of putting load on 3 is exactly as before: 3 and 4 are belted together, and 4 can be put in parallel either with 2 to assist it in driving 3, or with the power-house as before, to assist it in driving 1, according to the voltage of the armature that happens to be in 4. During the temperature run all the resistance in the shunt circuit of 3 is, of course, cut out; it is only inserted when tests for speed regulation are being made. All adjustment of volts, etc., is made through the resistances in connection with 1, 2, and 4. Since the motor on test is always—except in a special case to be referred to afterwards—loaded by running 4 in parallel with another generator, no external resistances are required for taking up waste power, and, therefore, the apparatus, just as it has been described, complies perfectly with the requisite of flexibility at both ends, as it has been shown how, by a suitable arrangement of pulleys, stock armatures, and field strengths, practically any desired voltage for testing can be obtained from a source of power at the same or any other voltage.

In actual practice 1, 2, 3, and 4 are mounted on a wooden bench 11ft. long, 2ft. 6in. wide, and 2ft. 6in. high. It has four legs on each side, 3ft. apart lengthwise, so that one pair of legs comes under each machine; and the whole is fixed down to the floor—cement in this case—as firmly as possible. A row of slide rails is fixed along each long side of the top, and four pairs of cross-rails sliding on these, and capable of being bolted down to them, carrying the four machines. An idea of the appearance of this bench with the machines on it, as well as of the other apparatus, is given in Fig. 2, for the opportunity of obtaining the original of which thanks are due to Messrs. J. H. Holmes and Co. The frame of resistance coils standing at the end of the bench is for a special purpose yet to be mentioned, and is shown, not as part of the regular apparatus, but simply because it is occasionally used in certain tests. All the switches, instruments, and terminals already described are mounted on a switchboard which stands at the end of the bench. In Fig. 2 one of these boards is seen complete, and part of another belonging to the bench, on which are seen the pulley ends of 1 and 2 belted together. The terminals, T and T_2, on the switchboard are connected for convenience to corresponding terminals, mounted on the under side of the bench top, and visible in the photograph, to avoid having loose wires lying over the floor between the board and the bench. Thus 1, 2, and 4 being for all practical purposes permanently coupled up, all that is necessary to get a motor running for test is to connect it to two pairs of terminals, armature and field respectively, which terminals are in practice all ready provided with wires for fixing at once to the motor terminals. The rest is all done at the switchboard. It is not necessary to go into much detail about the arrangement of the apparatus on the switchboard, since this is simply a matter of setting out a certain number of articles in what each designer considers to be the prettiest possible way. The over-all sizes of the two slate bases, positive and negative, is in this case 2ft. 10in. wide by 4ft. 11in. high, and they are mounted, as shown in the figure, on angle irons, so that the top is 6ft. 6in. from the floor. As the switchboards happen to be near a wall, all the starting and regulating resistances, as well as the ammeter shunts, are mounted on the wall, which leaves the back of the board quite clear. They could, of course, be mounted on iron brackets and supports carried from the vertical angle irons, but this is more

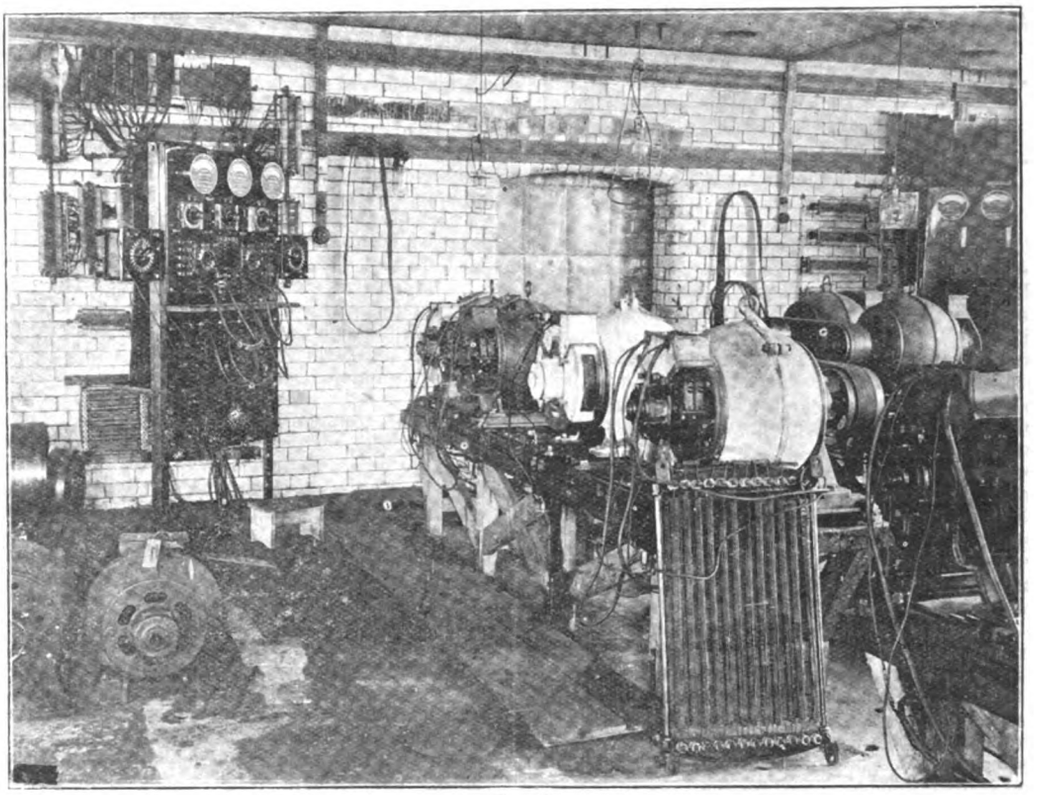

FIG. 2.

likely to cover up the back of the board with wires, which is a great evil, to be avoided studiously. It is, perhaps, unnecessary to mention that there are not actually five voltmeters, five ammeters A, and four ammeters A_1. There is one voltmeter only, reading 0-150 volts direct, with resistance to give 0-300, 0-450, and 0-600 volts, and a five-way double-pole switch couples it up, through a fine double-pole fuse on each circuit, to any one of the five V points of Fig. 1, which thus represent simply five places where volts may be measured. Similarly, the five points, A, are five separate shunts, connected, however, through a 10-way double-pole switch to the instrument, which has a small switch between the double-pole switch and its terminals so that it can be cut out of circuit in changing over the double-pole switch, in case of an overdose of current. The reason for the 10 ways is that each point A is actually two shunts in series, one giving full deflection with 15 amperes, the other with 150 amperes, so that the ammeter has two ranges. Similarly the four A_1 points are coupled through an eight-way switch to their instrument, and each A_1 has a 5-ampere and a 0·5-ampere shunt giving again two ranges on the ammeter according to the position of the double-pole selecting switch. These instruments are checked about once a month against a standard. As has already been suggested about the setting of carbon brushes, so also about all electrical instruments used by a number of different people in ordinary testing work, one must be in a perpetual state of scepticism, sometimes even of terror, lest they be inaccurate. Instruments of even the so-called "best make" will, especially when new, drop off in strength of field sometimes very rapidly, and by letting some go too long without checking they have been known to get as much as 10 per cent. out. It is a most useful piece of advice that one should never believe any single reading of any instrument in constant use. Only when one gets into a state of out-and-out unbelief like that does one take sufficiently vigorous steps to have the matter looked into with thorough regularity. This applies, of course, to supply companies as well as to manufacturers: there was once a time when the voltmeter of a certain company—shall it be said it was within a hundred miles of St. Nicholas's Cathedral, or shall that not be specified?—was found to be about eight volts low, and that same company declared that a monthly check of its instruments was taken regularly. This, therefore, is a matter equally important to us all.

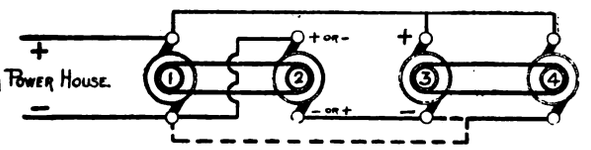

FIG. 3.

It may be said here that the cost of one complete set of apparatus as above described will probably be from £60 to £90—including everything but the armatures for 1, 2, and 4—according to the way the switchboard is fitted up and the type of instruments used, as well as the amount of wiring required and other possible variables dependent on individual circumstances. The number of tests per bench per day generally works out at about 1½ on the average under the conditions as to length of run already mentioned. As there are four benches, it is possible, as a rule, to keep each one for a given voltage, and to put each motor as it comes on the bench whose number 2 armature suits the case best. This involves less changing of armatures, but even if this has to be done, it is a very simple and short matter to accomplish.

In cases where the power-house voltage is only a few volts different from that of the motor to be tested, it is convenient sometimes to generate from 2 only the difference in volts and put this in series with the power-house voltage, thus increasing or diminishing it by the necessary amount. The connection would be as in Fig. 3, which shows only the armatures. The shunt of 3 must be excited from T_1 on the positive side and T_3 on the negative side in this case, and 4 can run, as shown by the full and dotted lines on the negative side, in parallel either with the power-house—that is, with 1—or with 3 as usual. This method saves transforming all the power required from one voltage to another, and is consequently a little more economical. It is interesting to see how well standard full-speed armatures work in for this in 2. For low-voltage motors the maximum difference between 1 and 3 will be 15 volts, as the possible range of working voltages is from 100 to 115: for medium voltages the maximum difference would be 60 volts—range 200 to 260 volts: while for high voltages the maximum difference would be 150 volts—range 400 to 550 volts. Thus for all cases a low-voltage armature is run in 2, and a high-voltage armature in 1, because if 1 is working at low volts it will run about quarter normal speed, and if the pulleys on 1 and 2 are in the ratio of about 1 : 2 in diameter, 2 will run at about one-eighth of normal speed, and will thus give out a maximum voltage of about 110/4 or 14 volts. Smaller differences could be got by weakening the field of 2. Similarly, for medium voltage, 1 will run at half speed, and equal pulleys on 1 and 2 will give half volts—about 55—from 2, which can be reduced, if necessary, by field regulation. For high volts, 1 will run at full speed, and by weakening the field of 1, and thus getting a higher speed, or by having a smaller pulley on 2 than on 1, 2 will give out 150 volts if required. This example is quoted at length, as it is useful for showing the great flexibility of the system.

It is a very simple matter to measure armature and series resistances on these benches. It is only necessary to disconnect the shunt of 3 and prevent the armature from turning, and then to send a current through the armature and series, if any, of 3 from 2, running at a reduced voltage. The drop of volts recorded on a low-reading voltmeter at once allows the required resistance to be calculated, the current giving this drop of volts being read on the ammeter A in circuit with B.

In ordinary tests the standard 10-b.h.p. frames are evidently large enough to test up to 15-b.h.p. motors, which is about the limit of weight that can be dealt with in this particular shop. If 4 runs in parallel with 3, and if 3 is a 15-b.h.p. motor with an efficiency of, say, 90 per cent., while the efficiency of 4 is, say, 88 per cent., then 4 will generate—neglecting belt losses, which with Hendry belts are very small—about ·88 of 15 b.h.p., or 13·2 h.p., which can easily be got out of this frame as a generator, while 3 will require to drive it about $\frac{1}{\cdot 9}$ of 15 h.p. Hence, since all that 4 generates is used for driving 3, 2 has to generate and supply to 3,

$$\left(\frac{1}{\cdot 9} - \cdot 88\right) \text{ of } 15 \text{ h.p.}$$

Assuming an efficiency of about 80 per cent. for 2, since, as will be seen, it is not working at full load, there will be required to drive 2, in order to get the above from it,

$$\frac{1}{\cdot 8}\left(\frac{1}{\cdot 9} - \cdot 88\right) \text{ of } 15 \text{ h.p.}$$

or, roughly, 4·4 h.p., which means that 1 must deliver 4·4 h.p. to 2, and will consequently, with an efficiency of about 80 per cent. also, take from the power-house about $\frac{4 \cdot 4}{\cdot 8}$, or 5·5 h.p., to drive the whole combination when 3 is a 15-b.h.p. motor. This is a much more economical method of running than when 4 is put in parallel with the power-house, as the latter has in that case to supply the losses between 1 and 4 which are due to a double transformation, and amount to nearly half as much again as the 5·5 h.p. mentioned above. Besides this, the load on 1 and 2 is now increased to 19 h.p. and 16·7 h.p. respectively, since 2 is no longer directly helped by 4, and this overload would probably overheat their armatures. Hence it is always better to run 4 and 3 in parallel if possible, but, because there may be cases where 4 has an armature of unsuitable winding and no other is available, 1, 2, and 4 are all chosen alike, of the standard 10-h.p. size. This has the further advantage of allowing all the armatures to be interchangeable.

For brake tests on the larger sizes of motors, 1 is not capable of developing enough power to drive the combination, as there is no longer any opportunity of running in parallel when 3 is loaded by a brake instead of by being belted to 4. In such a case, 1 and 2 on another bench must be used in addition, and the two 2 armatures put in parallel, unless it can be arranged to get the necessary voltage direct from the power-house.

In testing series-wound motors, the only difficulty is in starting up, as sufficient torque must be kept on the motor all the time to prevent it running away. This is accomplished by keeping the volts of 2 very low at first, and by putting 4 in parallel with 2 at the very start, and continually adjusting the field while raising the speed by means of increasing the volts of 2 so as to keep enough current in 3 to avoid a dangerous speed. Otherwise the procedure is just the same.

In testing small dynamos, the simplest method is to bring 4 along to the place of 3 on the bench and run it as a motor, while the dynamo on test is coupled up to the mains of 4. This avoids all changing over of ammeter flexibles which would be necessary if the dynamo were put in place of 3, everything being coupled up to suit the testing of a motor normally. Load is put on the dynamo 4 by putting it in parallel with the motor 3, and then, keeping the speed right by adjusting the field of 3—in doing which a tachometer belted to the dynamo or driven by a pin in the end of the shaft saves repeatedly counting the revolutions—the current from 4 is adjusted by altering its field in turn. Dynamos of very low voltage, such as milking boosters or plating dynamos, are most simply loaded by wasting the energy in a resistance, such as is shown in Fig. 2 at the end of the bench. This is the only case in which an external heavy current resistance is necessary, except in a few special cases where it is desired to test a motor specially for starting under full torque. In this case the resistance is put across the terminals of 4, which is then loaded as soon as it begins to rotate, being separately excited, and consequently puts load on 3 at once, instead of, as usual, having to be run up to the correct volts for putting it in parallel with 1 or 3, which

Digitized by Google

means that 3 would start light, as it does, of course, in all the usual tests. This resistance, then, is really a special movable piece of apparatus, only used in a few tests, and is not at all necessary in normal cases, which are dealt with, as has been seen, by an entirely permanent arrangement.

These benches have not as yet been actually used for alternating-current motors, but it is proposed to do so by replacing 1 and 2 by an alternating-current transformer fed from mains quite independently of the continuous-current board. The motor on test would be coupled up to the secondary of this transformer through a starting switch, which would probably be mounted on the transformer. The load would be put on the motor by belting it to 4 as before and

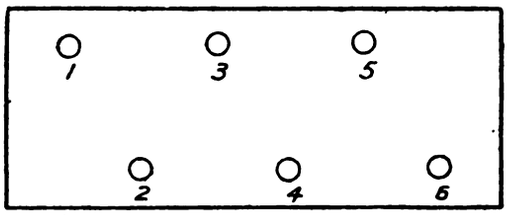

FIG. 4.—Blank.

running 4 in parallel with the power-house, the connection to which would always be available through the terminals on the continuous-current board. Thus the power given out by the motor, while it could not be used to help to drive itself, would help to drive continuous-current motors on other benches, and so cause them to take less from the power-house than would otherwise be necessary. The transformer would need to be specially designed with arrangements for varying the ratio of the primary and secondary turns through a large range. As regards instruments, while it would be possible to adapt the connections of the continuous-current board so as to use in the ammeters and voltmeter mounted on it, it is not proposed to do this, but rather to mount an ammeter, voltmeter, and wattmeter, with the necessary change-over switches for three-phase

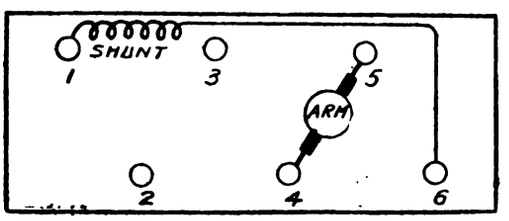

FIG. 5.—Shunt.

motors, on a light portable table, which could be placed by the side of the bench as required. The saving in time as compared with the necessary alteration in connections to use the continuous-current board instruments each time the motor on test was changed from continuous to alternating current would quite compensate for the necessity of providing an extra ammeter and voltmeter. The wattmeter would, of ocurse, be needed in any case for power factor measurements.

It may be interesting to mention, in conclusion, a terminal base for motors recently designed by the writer, and now used on the motors tested on these benches. It consists simply of a flat slab of porcelain held in the terminal box of the motor by a screw at each end (the holes for which are not shown in the illustrations), and provided with six holes, numbered

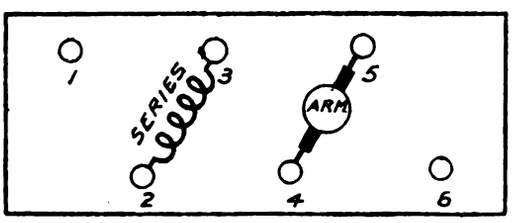

FIG. 6.—Series.

1 to 6, and so spaced that all the distances, 1-3, 3-5, 2-4, 4-6, 1-2, 2-3, 3-4, 4-5, and 5-6 are equal. Brass studs are fitted in as many holes as are required, and are provided with cable sockets for external mains in the proper places. The same block, as illustrated in Fig. 4, is used for shunt, series, and compound wound motors, such holes as are not required being simply left blank. The armature is in every case connected between 4 and 5, while the shunt is between 1 and 6, and the series between 2 and 3. The three types are shown in Figs. 5, 6, and 7. All the connections from the inside of the motor to the terminal base are brought to the under side of it, while on the upper side the external mains are connected up, and copper links, with holes at each end, distant by the amount of the pitch of the holes in the base from each other, are used to connect together pairs of studs as required by simply dropping them over the studs and clamping them down between two nuts. The advantage, which is great, is that no internal connections of the motor need to be altered if the direction of rotation has to be permanently or temporarily reversed; everything is done on the upper side of the terminal base by simply changing the links, and, in some cases, the position of the external mains. The variety of ways in which motors may have to be coupled up makes it impossible to describe all the possible combinations—as one example, however, is shown, in Fig. 8, the connections for a compound-wound motor with shunt and series regulation. To reverse the direction of rotation, all that is necessary is to change the link from 3-4, shown full, to 3-5, shown dotted, and

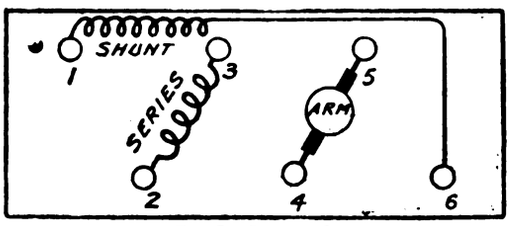

FIG. 7.—Compound.

to change one external main from 5 to 4, indicated by full and dotted lines. All the other wires remain exactly as before. The distance 3-4 being equal to 3-5, the same link serves in each case, as in fact it would for any other pair of studs on which the type of motor field winding and the way in which the motor was to be used required it to be placed. Two or more links may be used as required, and it is possible to use this base for absolutely every conceivable type of coupling up either a dynamo or a motor. A card sent out with each machine shows the proper place for links and mains for each direction of rotation, so that even the country-house gardener could not err, except deliberately.

There is much more that might be said on this subject and its side issues, but so long a paper must already have tended to

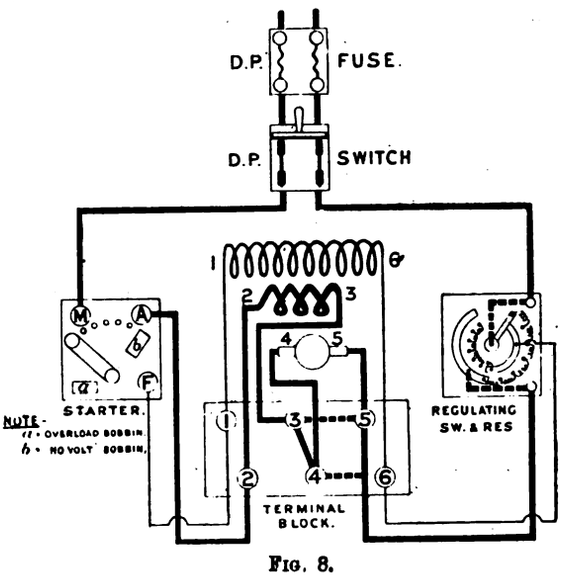

FIG. 8.

become wearisome, and must, therefore, now draw to a close with a renewed expression of the hope that some at least of what has been said may contain something which will prove not altogether uninteresting and unserviceable to some fellow-workers in this or some other province of the vast and ever-increasing domain of electrical engineering.

APPOINTMENTS VACANT.

Electrical Engineer, Pontypridd Urban District Council. Salary £91 per annum. Applications to the Clerk by Dec. 27.

Sales and Assistant Manager, electrical manufacturing and contracting company. Applications to 5,722, *The Electrical Review*, 4, Ludgate-hill, London, E.C. See advertisement.

Electrical Draughtsman. Box O 7, *Electrical Engineer* Office. See advertisement.

Premium Pupil, City Electrical Engineer, Carlisle. See advertisement.

Assistant, for central lighting station. Small premium. Apply Resident Engineer, Ross. See advertisement.

Shift Engineers (two), Brighton Corporation. Salary, £2. 10s. per week. See advertisement in last issue.

THE WIRING OF BALOR CASTLE: A MYSTERY.

[The following story has been sent us by a friend of the narrator's, whose manuscript he has slightly edited in order to improve the deficiencies of literary style. The story is one of that class that calls for the investigation of the Society for Psychical Research.—ED. *E. E.*]

My chief wireman burst into the office with a face as white as a sheet and collapsed on to a chair.

"Good heavens! Tom," I cried, "whatever is the matter?"

"I've seen it, sir," he whispered, clutching hold of the table and shaking all over like one with the ague. "It—he—O Lord——." He had fainted.

Two or three of the others were at the door, looking over each others' shoulders with scared faces. "What is all this about?" I asked, loosening Tom's scarf and applying my whisky flask to his lips. No one spoke. At last Mike the labourer came forward. "Shure, sorr, an' he's seen th' pooka," he said, crossing himself.

"The wha-at?" I cried.

"He means the ghost, yer honour," said another; "the one Mr. Murphy told ye of."

Murphy was the bailiff. Well, here was a pretty fix.

When I was asked by my employers to take charge of the work in connection with the electrical installation at Balor Castle, the seat of Lord ———, in the North of Ireland, I concluded that this would prove an important episode in my business career, and I accepted the offer with alacrity. Had I guessed at the time what the nature of the episode was to be, and the manner in which it would affect my prospects, I should not have been quite so eager. I am now out of a job, and writing this story in the hopes of getting something to eat—— But I am anticipating.

I took two good wiremen (of whom Tom Joyce was foreman) and two carpenters from London, and engaged the remainder of my staff, in the shape of a pipefitter, a wireman, and three labourers at Belfast. The family were away for the whole winter, and our comforts were attended to by Murphy, the bailiff. The men were found lodgings amongst the tenantry and I was given a bedroom and an "office" in the castle, where the housekeeper and one or two servants were in charge. No architect or consulting engineer had planned out the job (thank goodness), which was to be executed on a basis of cost. All that we knew was the schedule of lights and the positions had been fixed by his lordship in consultation with the bailiff. The plant was to come along afterwards, but for the present there was a good two months' wiring to do, and I was to draw on supply houses at Belfast and Dublin for the material. The castle was a very peculiar building. I should think it had been added to bit by bit every century since its original foundations were laid, but when that remote work was carried out even Murphy did not know. "Some folk say that this was originally the castle of Fin mac Coul," he told me when I first came, "but, anyway, his lordship knows more about it than I do, and he's got some pretty grim stones tacked on to the family, which, as you know, is descended from some of the Irish kings." I did not know, but I had heard that very few of these ancestors had died a natural death. "I suppose the castle is said to be haunted," I asked jestingly.

The bailiff looked hard at me. "I should advise you to leave that subject alone when speaking to those superstitious Irishmen you've got," he said, "or they'll vanish like a shot. There are various tales about, but I've never seen anything myself, nor known anyone who has. It is said that one of the kings of Ulster flayed his brother alive in this castle for attempting to run off with the queen, and that he had her majesty's throne covered with the skin, in order to remind her whenever she sat down that she was in the arms of her lover. The brother is reputed to haunt the old part of the castle, so, perhaps, you may see him." With that he left me, and we did not revert to the subject until the present incident occurred.

When I had brought Tom round, I questioned him and all the other men. It seems that one of the carpenters had overheard the bailiff's conversation with me and had promptly told his mates, who had no doubt all put themselves into a receptive mood for anything uncanny by discussing the matter over their grog with their respective landlords. I could not get Tom to give any coherent account of his adventure; all I could gather was that, having strayed for a moment into the older part of the edifice to plan out where a "run" was to come through, he had chipped some brickwork away, and had then seen (or thought he had seen) something horrible.

"Now look here, men," I said, "we are living in the twentieth century, and there is nothing that cannot be explained by scientific methods—no ghosts, or pookas, as you call them here, or anything." They all looked dubiously at Tom. "It is evident, too," I went on, "that Tom is not well, a touch of influenza, perhaps, and his disordered mind has conjured up a vision. (Tom shook his head.) So go to your work again, and I'll be around in a minute." I took Tom to his lodgings and made him lie down. Afterwards I returned to the castle, walked round the works, made the men accompany me to the place of Tom's fright, and, having reassured everybody, went back to my plans. I mentioned the matter to Murphy, who shook his head and said I had better have left that old brickwork alone.

Next day Tom was very ill, and I sent for a doctor, who pronounced him to be suffering from pneumonia. I telegraphed for another wireman, but in the meantime poor Tom died. Curious as it may seem, I was able to use this event as an argument to prove to his mates that Tom must have been delirious at the time when he had his alleged experience, and that put matters right again.

The new wireman arrived and things went on smoothly for a week or so. On the day when we started to work in earnest at the older part of the castle, I was assisting one of the carpenters in the long hall, when a terrible hubbub arose in another part. The door at the end was burst open, and one of the Irish labourers, named Mike, came through, followed by the two wiremen, the other carpenter, and Fergus, the second labourer. Mike rushed past me, calling loudly, "Ochone, yer honour, I've seen a bloody hand all covered wid blood, an' I'm not stoppin' f'r me money," and he fled along the corridor, fell at the top of some stairs, rolled to the bottom, and was picked up dead. Well, I had more trouble this time. The others had not seen what Mike thought he saw, but they followed him in his wild flight, from which it was clear that they were all more or less in a state of nerves and ready to believe anything. The death of Mike, although he smelled somewhat of drink, quite neutralised my argument about Tom; in fact, the two deaths were at once associated with the alleged apparition, and I pointed out in vain that Mike must have been drunk to go without his money. However, the pipefitter, a fat man with a red nose, who had been to sea, laughed at the whole thing, and by dint of some influence he had over his mate Tim succeeded in reassuring him and making him stick to the job. As for the others, it was only after I had promised to be on the works with them continually that they agreed not to lay down their tools. Such is the influence of a sceptic amongst a company of the superstitious.

After this the work went on without any further event for quite a fortnight, and we were beginning to forget all about our unhappy mates. In fact, I had gradually weaned myself away from the works in order to attend to my correspondence and plans when necessary. Suddenly our whole company was thrown into a fresh state of consternation. It happened in this way. One day the Belfast wireman, who was called O'Reilly, had not been seen for some time, so I sent Fergus, the remaining labourer (Tim was at the forge) to look for him. Hearing a loud yell, or rather shriek, we all rushed in the direction of the noise. Bursting into the turret room, an extraordinary sight presented itself. Fergus was leaning against the wall and pointing to the further door, whilst O'Reilly was lying at the foot of a trestle, mixed up with yards of 3/20 wire, apparently quite dead, and with a drawn look of intense horror on his face. Fergus found his voice when he saw us. "I saw th' pooka go through th' dure," he cried, "th' momint me mate fell, an' if it wasn't him, thin it was his shadder, be jabers."

"Come," I said, "you're a silly fellow if you have been frightened at shadows. Your mate here got twisted up with a wire and fell off the trestle whilst you were mooning." We made a most exhaustive search, and, as I expected, did not see or find anything, nor was there any evidence to show that anyone had been near the room. But nothing would pacify Fergus, who insisted on going back to Belfast at once. The result of all this was a great deal of unpleasantness. A second inquest was necessitated, and although "accidental death" was the only possible verdict, the local jury at first wanted to suggest that O'Reilly had seen something of the nature of which there was no evidence.

I sent a long report to my firm, who, however, only replied that the work must be got on with more quickly than had lately been the case. The bailiff was also rather distant; he would not discuss the matter, merely grumbling that everything had been all right until the infernal electricians came on the spot. Naturally the servants were somewhat disturbed, although they slept in quite a separate new wing from where we were working. Personally, I began to get uneasy. I was as sure as ever that here was one of those curious chains of circumstances or coincidences that all combined to point to a wrong conclusion. Nevertheless, the uncanny surroundings and the three deaths so quickly in succession had got on my nerves.

After this I made up my mind that I would have no more native labourers, and I determined to push on with the work as rapidly as possible, so as to get on to the newer part of the castle. Being short-handed, and also to inspire confidence, I myself took up the position of leading wireman. The work

Digitized by Google

went on again uneventfully for a couple of days, when a fresh incident occurred to disturb our equanimity. The pipefitter came to me one morning looking rather pale.

"If ye plase, sorr," he said, touching his cap, "I'll be afther taking my money an' goin' home."

"Whatever for?" I asked rather angrily.

"I name no raisons, sorr," he said, "but I cannot sthop at all."

Argument, abuse, entreaty, all were of no avail, and so I paid him off.

"Stop a minute, though," said I, as he was going. "Where's Tim?"

He grinned in rather a sickly way. "Tim's taken his hook!"

"Confound you all for a lot of cowards!" I cried. "What's to become of the work?"

The pipefitter approached me in a mysterious manner. "Look ye, sorr, I've been a bit about th' wur-ruld an' seen many grously sights. My advice to ye is, give over wid th' wur-ruk." And with that he went.

"Never!" I cried. "I'll see this infernal mystery through if I die for it!" As I uttered this exclamation my heart gave a jump. Did I, or did I not, see a reddish shadow at the window, between me and the light? I pulled myself together quickly, remembering that the man who had just gone out must have passed the window. My mind was evidently disordered. Taking a gulp of whisky, I called the four remaining men into the office. They were the two London wiremen and carpenters. At least I could rely on these.

"Now, mates," I said, "you see that Joe and his labourer have gone for no reason. With the exception of poor Tom, who died of pneumonia, all concerned in these desertions and accidents are Irishmen. Are we, five Englishmen, to be beaten by a supposed ghost, when we know such things don't exist? What do you say? Are we to go home and say that we failed to wire a castle because there was a ghost in it? What would your mates at home say? Shall we see this job through together, we five, and lay the ghost?"

After considerable discussion, from which it was clear that the men thought there must be something, but that it was capable of a solution, we decided that we would in future all work together, doing one room at a time; also that we would all sleep together in the turret room where O'Reilly fell, so that if anyone attempted to play any trick on us—an idea I encouraged—we should know how to deal with him.

The bailiff grumbled at the new arrangement, but I took no notice of his moods. That night we all moved into this room, and made up some shakedowns on the floor. It was arranged that if any person were to intrude we should all, without further ado, throw ourselves on him so as to allow of no chance of escape. For this purpose our beds were fixed at intervals all round the room. I had obtained the loan of a pack of cards and a box of dominoes from Murphy, and thus with our pipes and some good Irish whisky the evening passed away. At about midnight we retired. At first no one slept, but to our surprise we all awoke in the morning and agreed, with feelings of relief, that nothing had happened.

The next evening passed in a similar manner, and we retired at the same time, and woke up less surprised than the day before. But the third night—ah, well, I will tell you. I woke up with a feeling of uneasiness, and found the moonlight streaming into the room. Not feeling comfortable, I turned my head on the pillow, and saw—God! shall I ever forget it?—a man standing in the centre of the room, looking at me. I say looking at me, because his face was turned that way; but the eyeballs were sightless, and the man was—raw. *He had no skin on.* For what seemed an eternity my tongue was glued to my mouth and my blood froze. Then with a superhuman effort I screamed, "Help, mates! There, in the middle of the room!"

The men woke up instantaneously and with one bound we all jumped into the centre of the room and fell to the floor, grappling each other. How long we fought I cannot say, but someone got separated and struck a match. The silence that followed when we saw that there was no one to hold was broken by a low whining noise, which might have been the wind, and then the match went out.

"For heaven's sake light up again," cried one of the men, and we then lighted the candles, and so, with shattered nerves, waited for the day.

Now, the extraordinary part of the affair was that, when we talked the matter over, the other men all agreed that they had seen absolutely nothing themselves, but being woken up suddenly with a command, had done what they had been told. I thought it wisest, therefore, to maintain a silence regarding what I had seen, and tried to make myself and them believe it was a dream. The incident had, however, so thoroughly upset them, coming on the top of all the previous events, that one and all asked to be paid off and refused to stop another hour in the place. Personally, I felt too ill to argue the point, and I wired to my employers that I was coming straight back with the four men, and we left that very afternoon.

I mention here incidentally that when I got to Belfast I saw in a paper that my pipefitter had fallen between a train and the platform, and had been killed; whilst a labourer, in whom I recognised Fergus, had been found drowned in the docks.

When I returned home my firm would have nothing to do with me, and gave me my discharge. Since then it has fared ill with me. Business is bad, and the one or two jobs I might have got were refused me because I could not show a satisfactory reference from my last employers.

This morning, when looking at a paper in the free library (where I went to consult the "situations vacant" advertisements), I read that my pipefitter's labourer, Tim, had been killed at Belfast by the snapping of a hawser.

And so, although everyone of the alleged appearances at Balor Castle might be explained away, is it not a curious fact that all those who saw (or thought they saw) something have since died? All, that is, except myself, who must have had a nightmare, I am beginning to think.

And, as I said before, I am writing this account of my extraordinary experiences in the hopes of getting something to eat, but——

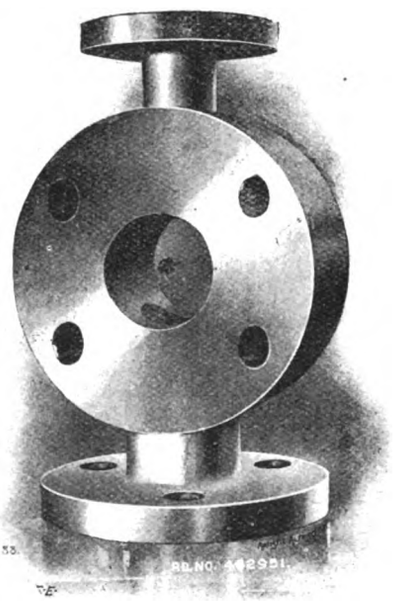
* * * * *

[The story ends here. Our correspondent who sent it says that he found his poor friend sitting at his writing, quite dead.—Ed. *E. E.*]

TRADE NOTICES AND NOVELTIES

Wrought Tees.

A tee of the special form recently introduced by Messrs. Meldrum Bros., Limited, of Timperley, near Manchester, is shown in the accompanying illustration. The distinguishing feature of this tee is that it



Meldrum's Wrought Tee.

is of wrought, not cast metal. It takes up much less space than the ordinary pattern, it is claimed, and, being machined from solid mild steel, is absolutely reliable—a fact which should alone recommend it especially for high pressures.

Catalogues, etc.

Knife Switches.—We have received from Messrs. Ferranti Limited a catalogue of their double-pole, double-throw, quick-break knife switches.

Artistic Fittings, etc.—From Messrs. O. C. Hawkes, Limited, Globe Works, Birmingham, we have a well-illustrated catalogue of their artistic fittings and heating stoves. The latter include some charming designs, and will appeal strongly to those who have a leaning towards art furniture.

Boardman's Arc Lamps.—Arc lamps for photographic, photo-process, stage, and medical purposes, etc., of the single-pair and multi-carbon types are dealt with in a list recently issued by the Boardman Electrical Patents Company, Limited, 10, Southwark Bridge-road, London, S.E. Some of these lamps have as many as four pairs of carbons in series, and yield up to 10,800 c.p.

Prometheus Heaters.—The British Prometheus Company, Limited, Kingston-on-Thames, have sent us a copy of their new catalogue of electric heaters, in which 56 different patterns of convectors, eight radiators, and one combined convector and radiator are described. The antique finish copper convectors are especially noteworthy. These are made of the finest hand-beaten metal, the workmanship employed being of the highest quality.

Digitized by Google

HEATING AND COOKING APPARATUS, ETC.—The General Electric Company, Limited, have just issued a new edition of their catalogue section "H" of heating and cooking apparatus, radiators, etc. The articles listed cover a wide range of usefulness. Special mention may be made of the auto service water-heaters and hot-water jugs (pp. 813-814), and of the new designs of glow radiators shown on p. 821. Electric irons, glue-pots, sealing-wax heaters, furnaces, etc., are included in great variety.

THE "O. AND I." ELECTRIC DRILLING MACHINE.—The United States Metallic Packing Company, Limited, Soho Works, Bradford, have sent us a copy of a booklet dealing with their "O. and I." portable electric drilling machine, which has already been largely adopted by the principal engineering firms in the United Kingdom. Illustrations showing the ready adaptability of the machine for the most awkward positions are included. It is especially suitable for use in connection with bridge-building and general constructional iron-work, shipbuilding and ship repair work, locomotive and stationary engine building, tramway trackwork, colliery work, and general engineering of all descriptions.

LABOUR-SAVING DEVICES.—A catalogue, which we have received from Messrs. Neville Bros., 7-9, James-street, Liverpool, illustrates a large variety of labour-saving machines and tools for use in electrical engineering works, etc. Among the contents we notice: vacuum drying and impregnating chambers for dynamo and motor armatures, coils, covered wire, etc.; automatic coil-winding machines; slot broaching and slitting machines for assembled stator and rotor stampings of induction motors; automatic tissue-papering machines for papering sheet iron for armature discs; armature disc varnishing machine; armature coil taping machines; armature disc, segment, and ring, automatic notching and dividing machines; hydraulic presses, and a large range of other useful machines to meet the requirements of the electrical manufacturing industry.

THE BATES-PEARD ANNEALING PROCESS.—We are indebted to the British Insulated and Helsby Cables, Limited, Prescot, Lancs., for an interesting description of the Bates-Peard patent automatic process of annealing non-ferrous metals. This process, which has already been widely adopted, provides not only for the annealing of metals absolutely free from oxides or scale, but has an automatic mechanical means of loading and unloading the furnace—reducing the labour cost to an irreducible minimum. It also has the advantage that only the article requiring to be annealed is heated up and cooled again, thus reducing the fuel used to a minimum also. The furnaces are at present in operation for annealing copper wire for the electrical trade's use, copper sheets, fillets, and tubes, brass tubes, nickel tubes, gold and silver articles for jewellers' use, fine brass, copper, and phosphor-bronze wires for weaving purposes. Needless to say, they are made in several types to meet these special requirements.

PERSONAL.

The Municipality of Johannesburg have appointed Mr. J. Foster as car-shed superintendent.

The Chichester Town Council have decided to increase the salary of the surveyor from £150 to £200 per annum.

The Radcliffe District Council have appointed Mr. Henry Wilkinson, of Radcliffe, electrical engineer to the Council at a salary of £150 per annum.

Mr. G. C. Milnes, of the Sandycroft Foundry Co., has been appointed switchboard attendant at the Lancaster Corporation electricity works.

Mr. Sydney Buxton, Postmaster-General, has appointed the Hon. Richard D. Denman to be his principal private secretary and Mr. H. F. McClintock as his assistant private secretary.

We are informed that Mr. G. H. Oswald Strick is leaving the Westinghouse Co.'s publishing department to take up the position of publicity manager with Messrs. Davidson and Co., of Belfast, the manufacturers of the well-known Sirocco fan.

The third annual dinner and smoking concert of the staff of the Salford Corporation electricity department was held last week. Mr. C. D. Taite (electrical engineer) presided over a large attendance, and was supported by Councillor Hodgson (chairman of the Salford Electricity Committee) and Councillor Barratt, J.P. (deputy-chairman).

The Aberdeen Tramways Committee have decided that the tramway manager shall be paid a salary of £300, and that he shall have charge of the undertaking, without the electrical equipment and track. The electrical work is to be under the charge of the electrical engineer, and the repair of the track in the hands of the burgh surveyor—as at present.

At the invitation of the chairman (Mr. F. J. Ferguson) of the Whitchurch and Pangbourne Electric Supply Co., a farewell dinner was given last week to Mr. A. T. Cooper, the managing director of the company, who is leaving on the 23rd of this month for Bombay, where he is to take up the management of a large electrical power and light undertaking for the authorities at Bombay.

The following increases of salaries have been made in the Electric Lighting and Tramways Committee of the East Ham Borough Council: Mr. T. Owen, traffic superintendent, from £200 to £210; Mr. W. G. Newton, outdoor assistant, £200 to £210; Mr. W. R. Elliott, station superintendent, £180 to £190; Mr. T. Aitken, mechanical engineer, £180 to £190; Mr. E. C. Baker, chief clerk, £140 to £150; Mr. A. H. W. Slaughter, clerk, £85 to £95; Mr. M. Deitchman, junior shift engineer, 30s. to 35s. per week; Mr. W. S. Westbury, car-shed foreman, 56s. to 58s. per week.

LEGAL INTELLIGENCE.

UNDERGROUND ELECTRIC RAILWAYS CO.

Appeal as to Stamp Duty.

In the House of Lords, Lords Halsbury, Robertson, and Lindley gave judgment on the 15th inst. in the case of the Underground Electric Railways Co. of London *v.* Commissioners of Inland Revenue.

This was an appeal by the company from a judgment of the Court of Appeal reversing a decision of Mr. Justice Channell upon a case stated by the Commissioners of Inland Revenue under the Stamp Act, 1891. The question was the amount of stamp duty payable on a sale by what may be called the old company to the new company. The consideration for the sale was a certain definite sum of money, and a further consideration was the payment of such a sum of money as should be equal to a dividend of 3 per cent. for each year on the amount for the time being paid up on such of the original ordinary share capital of five millions sterling in the new company as should for the time being have been issued by the new company. At the date of the agreement the whole of the ordinary share capital of £5,000,000 in the new company had been issued—viz., 500,000 shares of £10 each and on 100,000 of such shares £5 per share had been paid up, and on the remaining 400,000 shares £2 per share had been paid up, such payments amounting altogether to £1,300,000. Upon this sum a 3 per cent. dividend would amount to £39,000. The Commissioners were of opinion that this £39,000 was contingently payable according to the terms of the agreement either in perpetuity or for an indefinite period within the meaning of Section 56 (2) of the Stamp Act, 1891, and that in respect of this part of the consideration the stamp duty amounted to £3,900. That figure was arrived by multiplying the annual sum by 20 in accordance with the provisions of the Act and treating the capital sum so found as liable to a duty of 10s. per cent. The question was whether this sum of £3,900 was rightly included in assessing the stamp duty the agreement was liable to bear. Mr. Justice Channell gave judgment for the company, the Court of Appeal reversed the decision, and the company now appealed.

Their Lordships upheld the judgment of the Court of Appeal, and accordingly dismissed the appeal, with costs.

SWANSEA TELEPHONES.

The hearing was resumed on the 14th inst., before Lords Justices Vaughan-Williams, Stirling, and Ozcens-Hardy, on the appeal of the National Telephone Co. from a judgment of Mr. Justice Buckley, who in an action brought by the Corporation of Swansea against the company to enforce the giving of "reasonable facilities for intercommunication" for their telephonic subscribers, held that the facilities offered by the company amounted to a refusal to give any facilities at all within the meaning of the New Telegraph Act, 1899.

During the course of the reply of Mr. Astbury, K.C., on behalf of the Telephone Co., Lord Justice Stirling suggested the appointment of an expert to define what were reasonable facilities.

Mr. ASTBURY said he supposed that the greatest expert apart from themselves would be one from the Post Office, which was the next biggest system to that of the Telephone Co. They were opponents of the company and their rivals in London, but he had not the slightest objection to their Lordships asking the principal engineer of the Post Office system in London to go down to Swansea to look at the systems and state what in his opinion was the best way of affording facilities.

Mr. R. J. PARKER, on behalf of the Corporation, said he would rather that the matter should not be referred to the chief engineer of the Post Office, but left entirely in the hands of their Lordships.

Lord Justice VAUGHAN-WILLIAMS said that any expert appointed by the Court would have to have inspection of the company's works at Swansea.

Mr. DANCKWERTS, K.C., on behalf of the company, said there would be no difficulty about that.

Lord Justice VAUGHAN-WILLIAMS: It is obvious that our judgment must stand over for the present.

A MANCHESTER TRAMWAY ARBITRATION.

In the House of Lords on the 16th inst. Lords Macnaghten, Robertson, and Lindley gave judgment on an arbitration between the Manchester Carriage and Tramway Co. and the Swinton and Pendlebury Urban District Council. The appellant was the liquidator of the tramway company, and the difficulty of the case arose, to some extent, from the fact that the arbitrator whose award was under consideration (Sir Frederick Bramwell) had since died, and therefore it was impossible to refer the matter back to him to clear up a question of doubt that had arisen as to the exact meaning of a part of the award. The local authority decided to purchase the company's undertaking. The question was whether a depôt situated outside the Council's district, but suitable to and used for the purposes of such part of the undertaking as was within such district, was to be taken and paid for by the Council. The arbitrator found that the value of the tramway was £24,689, the value of the land and buildings constituting the depôt in dispute, known as the Church-street depôt, was £24,000, and the value of the fixtures and fittings at the depôt £308, making altogether a total of £49,006. Should the Court be of opinion that the Council was not compellable to purchase the Church-street depôt, then the items of £24,009 and £308 must be deducted from the above total, and in such event he awarded the £24,689 only. The special case came before Mr. Justice Channell, who held that the Council were bound to pay for the Church-street depôt. The District Council appealed, and the Court of Appeal came to the conclusion that

Digitized by Google

as the finding of the arbitrator was ambiguous as to whether the depôt was suitable to and used for the purposes of the undertaking the tramway company could not compel the local authority to purchase the depôt. The tramway company thereupon carried the matter to their Lordships' House.

Their Lordships held that the local authority was liable to take and pay for the Church-street depôt, and accordingly allowed the appeal with costs.

WATER RIGHTS.

The Llanrwst Electricity Supply Co v. the Llanrwst Urban District Council and the Geirionydd Rural District Council

This action was heard before Mr. Justice Warrington in the Chancery Court, and was brought to restrain an alleged interference by the defendants with the plaintiffs' water rights. In pronouncing judgment, his Lordship said the plaintiffs claimed to be entitled to certain water rights in respect of a mountain stream running past their works from Llyn Crafnant down to the River Conway; the particular right they now insisted upon was to have a flow of water from Llyn Crafnant through two 7in. pipes at all times necessary for the working of the power demised to them for the purposes of their business, which in the present case meant to have a full flow of water during the night. In other words, the plaintiffs asserted a right to have a full flow of water during such hours as they might themselves select for their own convenience. The water rights in question were obtained from a natural stream falling rapidly down on its way from the lake above, and from the evidence it appeared that this flow had been regulated for many years for the common benefit of all their tenants by the owners of the lake or their licensees by artificial means which had been erected in and prior to the year 1874. On these facts the plaintiffs, therefore, were not entitled to the natural rights of ordinary riparian owners, but their rights, if any, were contractual, and the onus was on them to make out from the documents in the case that they were entitled to have a full flow of water at certain hours of the day or night to be selected by them. In other words, the plaintiffs' rights depended upon contract, for his Lordship found as a fact that but for the control of the flow from the lake exercised by means of the sluice in 1874, and after that by the valves put up by the defendants, the stream could not have been used for all the purposes to which it had been put throughout the whole year. Having stated the facts and examined in detail the leases, his Lordship said what he had to determine was whether on the construction of these documents the plaintiffs had made out their right to the particular claim they now made, and his Lordship came to the conclusion that they had not made out their right to such a claim. All that they appeared to have was an undefined right to use the water flowing down this stream. The defendants were the lessees of the lake and the embankment, and the lease of 1884 did not contain any stipulations which bound the then owner of the lake and embankment to use the valves in these pipes in any particular way. The right set up by the plaintiffs in their statement of claim had not been established, and there must, therefore, be judgment for the defendants, with costs.

OVERHEAD v. UNDERGROUND TELEGRAPH WIRES.

County Court Action.

A case of considerable interest to local authorities and others came before his Honour Judge Emden at Bromley County Court on the 15th inst. It was a case in which application was made under the Telegraph Act of 1878 by the Postmaster-General for the hearing and determination of a difference which has arisen between himself and the Foots Cray Urban District Council in respect of the placing of a telegraph line consisting of posts and the wires and apparatus connected therewith in, upon, over, along, or across Station-road, Sidcup, which is in the district of the respondents. Formal notice was served upon the respondents on Aug. 3 last applying for their consent to the proposal, which they failed to give, and as a result the applicant claimed an award by the learned judge consenting to the erection of the proposed line.

The basis of the refusal was that Station-road was too narrow for the erection of the proposed line, and the reply of the appellant was that this was a good wide road. As to the suggestion that the wires should be laid underground, the contention of the appellants was that the excavating would be too expensive. It would cost about three three times as much compared with the estimated cost of the erection of overhead wires, and it was their opinion that they would not be justified in incurring such expense. The submission was that the Foots Cray Council were not justified in refusing this specific application, and the Postmaster-General therefore applied to his Honour for his consent to his proposal to provide telegraphic facilities in the road in question.

Mr. MARTIN FENN ROBERTS, an assistant engineer-in-chief to the Post Office, said the cost of carrying the wires underground would be £145. 6s. 9d., but if erected overhead, as they proposed, the cost would amount to only £50. 3s. 2d. He had prepared plans showing the width of Station-road at two points. The minimum width of the road was 35ft., and of the footpath 6ft. 8in. In some places, however, the road was 40ft. and the footpath 7ft. 3in. in width—in some places, in fact, he believed the path was 8ft. in width. Witness also gave the dimensions of the posts it is proposed to erect, and produced photographs of the same.

On behalf of the Urban Council it was stated that they were anxious and willing to assist the Postmaster-General in giving the utmost telegraphic and telephonic facilities in the district of Foots Cray. They, however, thought he had two alternatives to the proposal to erect overhead wires. The Council offered to pay the expenses of excavating the trenches for the pipes, filling in the ground, and making good the surface with all speed.

HIS HONOUR, in giving his award in favour of underground wires, said that it was subject to the Council's agreeing to excavate and make good the surface with all convenient speed, and the Postmaster-General, through his representative in court, consenting to put the wires underground.

COMPENSATION CLAIM AGAINST TRAMWAY ENGINEERS.

Sheriff Sym in Perth Sheriff Court on the 15th inst. closed the record in an action at the instance of John Dickson, Perth, against Robert W. Blackwell and Co., engineers, Perth, for payment of the sum of £300 at common law, or £178 under the Employers' Liability Act, 1880. Pursuer in his condescendence states that on May 22 last he was in the employment of the defenders, and was engaged, along with other workmen, lifting tramway rails on to a lorry at the Shore. While the pursuer, along with four workmen, was lifting one of the rails on the instructions of Robert Myers, the foreman, it canted, fell, and injured the pursuer. It is contended that if a sufficient number of workmen had been provided and appointed they would have been able to prevent the falling of the rail, and no injury would have been sustained. By the falling of the rail the pursuer's left hand was badly crushed, and the middle and right fingers had to be amputated. The pursuer also received a severe fracture of the large toe of the left foot. These injuries had caused pursuer great pain, and he would be unable to do any work for a considerable time, and would be permanently and seriously affected through the loss of his fingers in following his usual occupation. At the time of the accident pursuer was earning 23s. a week.

The defenders plead that the number of men provided to lift the rail in question was ample for the purpose, and in point of fact large quantities of the rails had been safely and satisfactorily loaded by four or five men for some months prior to the accident. They further plead that the action is irrelevant, and that the pursuer's injuries, being due to the fault of persons engaged in a common employment with him, he is not entitled to claim compensation from a common employer in respect thereof. In any case the damages claimed are excessive.

ACTIONS AGAINST TRAMWAY CONTRACTORS.

Two claims were recently heard in the Record Court in Ireland before the Lord Chief Baron for damages arising out of personal injuries received owing to the excavations on the roadway necessary for the purpose of relaying tramways. The defendants in both cases were Messrs. J. G. White and Co., and in the first action the jury found that the obstruction was not reasonably lighted, and returned a verdict for plaintiffs, with assessed damages at £17.

In the second case, plaintiff claimed that defendants wrongfully raised portion of a public footpath on Woodstock-road, in Belfast, and left it in such a condition as to be a danger to the public, whereby the plaintiff, when lawfully using the footpath, caught his foot, hurt his kneecap, and was unable to attend to his duties.

The jury again found in favour of plaintiff, and assessed damages at £300.

TRAMCAR ACCIDENT.

The action Williams *v.* the Salford Corporation, heard before Judge Shee, K.C., at the Court of Record last week, was a claim for damages sustained owing to the carelessness of a tramcar driver in the employ of the Corporation.

The jury returned a verdict for plaintiff, and awarded her £225 damages.

SEQUEL TO ELECTRICAL FRAUDS CASE.

At the Wandsworth Bankruptcy Court, before Mr. Registrar Willoughby, George Webber, formerly an ironmonger, Putney, who was recently convicted with William Leslie and Alice Cheeseman at the Central Criminal Court of complicity in the electrical appliance frauds, was brought up in custody from Brixton Prison to undergo his public examination. According to his statement of affairs, his gross liabilities amount to £30,000, and he attributed his insolvency to the orders which Leslie induced him to sign.

The trustee asked for an extension of three months in which to consider the numerous proofs, which the registrar granted, and the examination was adjourned.

COMPANIES' MEETINGS AND REPORTS.

BLACKPOOL TRAMWAYS.

The annual meetings of the Blackpool, St. Annes, and Lytham Tramways Co. and the Blackpool Electric Tramways (South) were held consecutively at Blackpool on the 18th inst., shareholders in the latter Company being privileged to be present at both meetings.

Opening the meeting of the former Company, Mr. THOMAS BLANE (chairman) pointed out that the receipts of the past year had been slightly better, but the full advantage of the arrangement to run into Blackpool would not be felt until next year, when he expected that the gross receipts would be materially increased.

Mr. MARSDEN HARGREAVE criticised the balance-sheet, pointing out that the working expenses of the tramway were over 70 per cent.

Digitized by Google

of the gross takings, which with management expenses made the net expenses nearly 80 per cent. Unless these items could be materially reduced, he held out little hope for the debenture holders receiving full interest, and absolutely no hope for the shareholders. He dissected management expenses, drawing attention to the fact that the receivers were getting £539.

Mr. Smith, retiring director, was re-elected.

At the close of the meeting, the meeting of the Blackpool Electric Tramways Co. (South) was held.

Mr. GUTHRIE (the chairman) spoke at length regarding the relative position of the two companies, and regretted the debenture holders' action in opposing the winding-up of the company and a division of the assets, consisting entirely of shares in the Blackpool, St. Annes, and Lytham Co., amongst the shareholders.

BRITISH WESTINGHOUSE ELECTRIC AND MANUFACTURING.

The sixth annual general meeting of this Company was held on the 18th inst., Mr. William I. Buchanan presiding.

The CHAIRMAN, in moving the adoption of the report and accounts for the year ending July 31 last (a copy of which appeared in our issue last week), said the year had been one of disappointment to the Board. The controlling factor which guided those who created this large industrial undertaking was not the immediate present, but the future industrial development that must follow the constantly increasing uses to which electric power was being put—a feature yet in its childhood in this country. Certainly the moment had not been reached when either the capacity or the potential ability of their immense plant had had an opportunity to justify the faith and belief of almost every competent person in touch with the development of electrical traction and power undertakings in this country. The difficulties met with centred chiefly around the keen competition the Company had to meet in the sale of their product as a result of a very light demand. These had brought constantly lowering prices with them, with the invariable result—namely, abnormally reduced trading profits. The number of orders received during the year was nearly double that for the previous year, and three times that for the year 1903, while the total value, even in the absence of any large orders, had remained approximately that of the previous year. Another encouraging feature was the fact that the business being done by the Company in the Colonies was increasing. The competition which the Company had to meet at home was still disadvantageously affected by Continental companies, and he saw little likelihood of any immediate change in this vital matter. The chairman referred to the experimental application of single-phase electrical traction to one of our prominent railway lines, the order for which was given to a Continental company. The work in question was awarded this Continental company under terms heretofore unknown. It was not alone a matter of the price at which the given case would be taken that was involved, but, more important, the pernicious effect exercised on prices as a whole by the constant presence of such a competition. So long, however, as the public policy of a country encouraged competition within its own borders from its strongest and most active rival, just so long would that country's industrial undertakings be powerless to do other than try to meet it by following down prices to the point of factory costs, or, in many cases, see work they urgently required for their own shops go abroad to help reduce the shop costs of their foreign competitors, who themselves enjoyed freedom from outside interference within their own country through economic legislation. He was, therefore, unable to hold out any strong encouragement for the shareholders to look for a marked change during the present year, either in an advance in prices or in an increase in the volume of their output.

Mr. J. H. LUKACH seconded the motion.

Dr. DAVID BROWNE declared that the chairman's statement left him almost without hope, and complained that the undertaking had been worked with great extravagance. The retirement of Sir Joseph Lawrence, M.P., and the accession to the Board of Mr. Newcomb Carlton, a vice-president of the Westinghouse Electric and Manufacturing Co. of America, he thought, indicated a desire on the part of the American company to squeeze them out. He moved as an amendment that the report be not adopted.

Mr. MACKENZIE supported the amendment, and contrasted the condition of the concern with the prosperous state of the American company, while another shareholder referred to the fact that the Canadian company also was able to pay a dividend.

The CHAIRMAN explained that Mr. Westinghouse was unable to be present, as he desired, owing to engagements in America, and he (Mr. Buchanan) had taken the responsibility for not postponing the meeting further. The suggestion that there was some ulterior purpose in the relations of the American and British companies was untenable to any man who considered the fact that the interests of the American Westinghouse Co. in this Company had been constantly increasing. The holdings of the American company and Mr. Westinghouse himself in the preference shares had increased by more than 6,000 shares within the past year. Not one had been sold; not one would be sold. These gentlemen would not put their money into the concern in preference shares if they did not believe in it.

Sir JOSEPH LAWRENCE, M.P., repudiated the suggestion that his retirement was due to any want of confidence in this undertaking. It was due to a desire cherished for some considerable time to lessen his cares and responsibilities. He bore testimony to the great difficulties which the directors had experienced in meeting foreign competition, and said it was absolutely impossible for electrical companies in this country to conduct their business with ultimate benefit to themselves by reason of this competition. Foreign companies, like the Berlin Electrical Co., came into this country backed by enormous capital and buttressed by the cartel arrangements, one feature of which was that a combination of electrical manufacturers in Germany guaranteed to those of their members who competed outside Germany the difference between the low prices they had to take in Great Britain and the prices they could get in Germany. As to the Brighton Railway contract, he said the terms of it were impossible. One of the conditions was that they were to wait 18 months for their money. No business could succeed that was tied down by such uncommercial conditions.

After some further discussion the amendment was withdrawn, and the report declared unanimously carried.

MANX ELECTRIC RAILWAY.

The report of the Manx Co. for the year ended Sept. 30, 1905, to be submitted at the meeting on the 3rd prox., shows gross receipts £32,638 and gross expenditure £15,349, leaving net earnings £17 289. After deducting debenture interest, £9,054. and adding balance brought forward, £780, there is a credit balance of £9,015. After payment of dividend due on the preference shares there remains a balance of £2,205, which the directors propose should be carried forward. During the year a further capital expenditure has taken place of £5,995, from which the Company has not yet reaped the full benefit; whilst preference shares for £6,325 and debenture stock for £2,500 have been issued. A considerable amount has again been spent out of revenue in maintenance and renewals, and the whole line is kept in good repair. The summer season in the Isle of Man has shown considerable improvement over the previous year. Visitors have been a good deal more numerous, and passengers carried during the past 12 months totalled 501,696, as compared with 472,556 carried during the previous 12 months.

PROVINCIAL TRAMWAYS.

The report of this Company for the year ended Sept. 30 last states that net revenue received from the local companies has been £24,050, against £24,095 last year. To this must be added amount brought forward (£3,496) and transfer fees (£19), together £27,565. There has been set aside for depreciation £7,000, and the directors now recommend a dividend on the ordinary shares of 4s. per share, making 7s. per share for the year. The balance to be carried forward will be £2,752. Through unforeseen difficulties in connection with the construction of the track and overhead work, and also in consequence of delay in the completion of the power station plant, the directors regret that their expectations that their undertaking would have been completed and working by electric traction in the spring of this year, have not been realised; the lines are, however, now completed, and the machinery has been running for some short time with satisfactory results. The Board of Trade inspections will be held at an early date, and upon the receipt of the certificate the line will be at once worked by electric traction. The Bill in Parliament for an extension to Privett Station and for power to supply electric energy to a local railway duly passed and received the Royal assent. In June last the directors issued a circular to the shareholders in order to elicit their views as to the desirability of writing off lost capital by reducing the nominal value of the ordinary shares of the Company. The result was out of 870 shareholders, 230, representing about 31 per cent. of the ordinary capital, signified their assent; 105 shareholders, representing abont 14 per cent., signified their dissent; and 535, representing about 55 per cent., did not reply. The circular stated that those shareholders who did not reply would be assumed to assent. The directors, therefore, conclude that a considerable majority of the shareholders are in favour of the reduction. The matter is somewhat complex, and requires that all the details shall be carefully worked out as, if it were duly approved by the shareholders, it would afterwards have to be submitted to the Court for confirmation. The directors do not, therefore, propose to submit the matter upon the present occasion, but they have the scheme under careful consideration.

COSTA RICA ELECTRIC LIGHT AND TRACTION.

The report of this Company for the year ended June 30 last states that the net earnings in Costa Rica amount to £10,159, as against £9,155 the previous year. Since the accounts now presented were made up, returns from Costa Rica for the four succeeding months indicate an average profit of £1,040 per month, or at the rate of over £12 000 per annum. A further issue of debentures to the amount of £5,000 was made during the year in accordance with the authority given at the general meetings of November, 1902, in repayment of the balance of Mr. Keith's advances on capital account. The lighting concession under which the Company is working in San José was dated to run out on Dec. 31 next. A new concession of 50 years from Jan. 1, 1906, both for lighting and tramway, has been granted to the Company by the municipality on equitable terms, subject to confirmation by the President of the Republic. The small plant at Cartago, from which a very insignificant revenue was derived, has been disposed of to a local enterprise, and the proceeds are being devoted to improvements in the San José plant. A storage reservoir increasing the capacity of the Maria Aguilar River by 3,000 8-c.p. lamps was completed in June last. The tramway sub-station at Torres and the workshops have been removed to the head office in San José, thereby facilitating supervision and effecting economies both in time and labour. As practically all the power at present at the Company's disposal has been taken up, and the management is compelled to refuse new customers, it has become necessary to develop further water power and to instal further machinery. Surveys have been made and estimates obtained showing that for a sum of £8,000 to £9,000 the lighting capacity on the Tiribi River can be increased from 15,000 as at present to 36,000 8-c.p. lamps. The directors propose to make an early issue of deben-

Digitized by Google

tures for this purpose, and the stock and debenture holders will be given an opportunity of subscribing to the issue. During the year the gold premium has remained steady at about 110 per cent. The general manager certifies that all buildings, machinery, plant, and permanent way have been kept in good working order.

NEW COMPANIES REGISTERED.

Kamm's Zerograph Syndicate (1905), Limited. — Capital, £24,000. Object: to acquire the business of manufacturers of telegraphic and other instruments and typewriters carried on at 27, Powell-street, Goswell-road, E.C., as Kamm's Zerograph Syndicate, Limited, to adopt an agreement with the said company and H. B. Harvey, the liquidator thereof, etc. Registered office: 27, Powell-street, Goswell-road, E.C.

Automatic Electric Block Signalling Co., Limited.—Capital, £1,000. Object: to adopt an agreement with the Electric Railway Signalling Syndicate, Limited, to acquire any patents and inventions, and to carry on the business of electricians, engineers, suppliers of electricity and electrical installations and machinery for light, signalling, heat, motive power and other purposes, manufacturers of electrical apparatus, etc. Registered office: 302, Finsbury-pavement, E.C.

Macclesfield Tramways Syndicate, Limited.—Capital, £5,000. Object: to acquire, construct, equip, maintain, and work railways, tramways, or light railways in the United Kingdom, whether worked by electricity or other power, and to carry on the business of railway and tramway proprietors, carriers of passengers and goods, suppliers of electricity for power or otherwise, engineers, etc. No initial public issue. The first directors (to number not less than three nor more than seven) are to be appointed by the signatories. Qualification, £100.

Liens Registered.

Carbonite and Arborite Syndicate, Limited, London, E.C.—Lien registered Dec. 6 for £500 4½ per cent. debentures, part of £2,500 authorised. No trustees. Charged on all the property, including the uncalled capital.

Guildford Electricity Supply Co., Limited. — Twenty-five thousand pound debentures created Nov. 21 and dated Nov. 30, 1905, have been registered. Property charged: the company's undertaking and property, present and future, including uncalled capital. No trustees.

Electolytic Alkali Co., Limited (Middlewich).—Issue on Nov. 30 of £300 4½ per cent. first mortgage debentures, part of a series created July 9, 1905, to secure £50,000. Charged on the company's undertaking and property, present and future, including uncalled capital. Trustees: Liverpool Mortgage Insurance Co., Limited, 6, Castle-street, Liverpool. Total amount previously issued of same series, £20,850.

Perth Electric Tramways, Limited —Issue on Nov. 15 of £600 debentures, part of a series created Dec. 22, 1903, to secure £50,000, charged on the company's undertaking and property, present and future, including uncalled capital, subject to £200,000 first debenture stock. Trustees: Lord Arthur Butler, 7, Portman-square, W., and J. S. Austen, 68, Dashwood House, E.C. Total amount previously issued of same series, £39,000.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Calcutta.—The Corporation propose to remove their conservancy refuse by means of electric motor wagons.

Pontypridd.—The Urban District Council invite tenders for cable conduits. Tenders to the Clerk by Jan. 1.

Cardiff —The Parks Committee invite tenders for an electric launch for Roath Lake, not exceeding 30ft. in length, to carry 40 persons.

St. Marylebone.—The Electricity Supply Committee invite tenders for house service fuse-boxes. Tenders by Jan. 10. See advertisement.

St. Marylebone.—The Electricity Supply Committee invite tenders for various stores. Tender by Jan. 10. Full particulars in advertisement columns.

Puente Genil (Cordoba, Spain).—The Municipality require tenders for provision and maintenance of electric lighting for 16 years. Tenders by Jan. 5.

St. Pancras.—Tenders are invited for supplying (Section A) arc lamp columns and cradles; (B) open-type arc lamps. Tenders by noon on Jan. 9. See advertisement.

Grimsby.—The Corporation require tenders for contracts contained in Specifications No. 35 39 and 43-45, for electrical plant, cables, and buildings. Tenders by Jan. 5, 1906.

Paris.—The Post and Telegraph Department, 13, Rue de Grenelle, require tenders for four lots of rubber-insulated cables and six lots of copper wire and copper junction boxes. Tenders by Dec. 23.

Leyton (Essex).—The Urban District Council invite tenders for the construction of nine miles of double tramway track, and for all materials connected therewith. Tenders by 7 p.m. on Jan. 8.

Croydon.—The Guardians invite tenders for the installation of electric fire-alarms at the infirmary. Tenders to Mr. H. List, clerk, Union Offices, Mayday-road, Thornton Heath, by 4 p.m. on Jan. 8.

Madrid.—The Public Works Department require tenders for a concession to construct and work an electric tramway between Santander and Astillero. Guarantee, 8,195 pesetas. Tenders by Jan. 30, 1906.

Gravesend.—The engineer has been authorised to forward specifications to a number of firms asking for tenders for economisers to be submitted to the town clerk so as to be available for committee during January next.

Manchester.—Tenders are invited for laying underground telephone pipes, with other appurtenant works. Tenders to the Chairman of the Special Committee re Telephones, City Surveyor's Office, by 10 a.m. on Jan. 2.

Launceston (Tasmania).—Tenders are invited for the supply of 500 or more electric meters and for maximum demand indicators. Tenders to Mr. C. W. Rocher, town clerk, Town Hall, Launceston, Tasmania, by 12 noon on Jan. 15.

Sofia (Bulgaria).—Tenders are invited for the electric lighting of the Government Cadet School. Tenders by Jan. 19. Offers must be addressed in the Bulgarian language and be accompanied by a deposit of 5 per cent. of the amount of the tender.

Spain.—The *Gaceta de Madrid* contains a notice inviting tenders, which will be opened at noon on Jan. 30 at the Directorate-General of Public Works, Madrid, for the concession of an electric tramway between Santander and Astillero. A deposit of about £208 is required to qualify any tender.

Brussels.—Tenders are required for the electric lighting of the marine hospital. Conditions may be obtained from the Secrétaire général de l'administration des hospices et secours de la ville de Bruxelles, Boulevard du Jardin botanique, hôpital St. Jean, Brussels. Tenders by Jan. 5, 1906.

Castlerea.—The Rural District Council invite tenders for the construction of works for lighting the town of Ballaghaderreen: (1) builders' work; (2) hydraulic turbine plant; (3) electrical work. Specifications and particulars may be had from Mr. C. Mulvany, M.I.C.E., Engineer's Office, Athlone, on payment of £1 as a deposit, returnable after receipt of bona fide tender. Tenders by Dec. 23.

Southport.—Tenders are to be obtained by the Town Council for the supply of a battery of accumulators and a booster to be worked in connection with the traction sets; a shaping machine is to be purchased for the workshop; and the electrical engineer has been instructed to rewind the field magnets of three alternators as soon as convenient, and to provide an atmospheric exhaust to the No. 3 traction set.

RESULTS OF TENDERS.

Croydon.—The Council have accepted the tender of the British Thomson-Houston Company, at £1,450, for a three-machine motor-generator.

Weston-Super-Mare.—The Urban District Council have agreed to let the National Telephone Co. install certain fire-alarms on a seven years' agreement, at £42 per annum.

Howrah.—The Agent of the E.I.R. has accepted the tender of T. E. Thompson and Co., of Calcutta, for the supply of the electrical equipment of Howrah new station with fans and lights at a cost of about Rs 20,000.—*Indian Engineering.*

Condensing Plant.—The Haste Pump Co., Crown-buildings, Old Broad-street, London, E.C., have received orders from the War Office for three sets of surface-condensing plant of the counter current type, including Edwards patent air-pumps; also separate contract for a large direct-acting steam pumping engine.

London.—The London County Council have received the following tenders for supply, delivery, and erection of steelwork required in connection with the second portion of the Greenwich electricity generating station:

E. C. and J. C. Keay, Birmingham*	£46,490	7	10
Clayton, Son, and Co., Leeds	47,725	11	2
J. Westwood and Co., London	49,451	5	6
Braithwaite and Kirk, West Bromwich	50,275	1	10
Thames Ironworks, Shipbuilding, and Engineering Co., London	53,139	5	7
Redpath, Brown, and Co., London	54,660	4	8
Head, Wrightson, and Co., Thornaby-on-Tees	54,918	6	2
J. Butler and Co.'s Trustees, Leeds	57,897	7	7

* Recommended for acceptance.

The offer of J. Mowlem and Co. to execute for a sum of £20,872 the roadwork and platelaying in connection with the reconstruction of the existing tramways in Vauxhall Bridge road, between Victoria Station and Vauxhall Bridge, for the underground conduit system of electric traction, has been accepted. The British Westinghouse Electric and Manufacturing Co. will be allowed to sublet to the undermentioned firms (or to such other persons or firms as may be approved by the Council's chief officer of tramways) the following portions of the work included in the company's contract for the supply of 34 tramcar trucks and electrical equipments—namely: (1) the manufacture of the trucks to Mountain and Gibson, of Bury, and (2) to A. Reyrolle and Co., of Hebburn-on-Tyne, for the manufacture of the plugs for car ploughs.

Lowestoft.—The Town Council have adopted the recommendation of the Joint Tramways and Electric Committee respecting the charge made for current supplied to the tramways undertaking, which was to the effect that the Electric Lighting Committee should return the equivalent of ¼d. per unit for all electricity used for tramway purposes for the year ended Sept. 30, 1905, and for the year ending Sept. 30, 1906, current for tramway purposes should be charged at 2¼d. per unit.

BUSINESS NOTES.

TRACTION.

Dumbarton.—The Town Council have formally agreed to petition against the Dumbarton Tramways Order.

Mansfield.—The Board of Trade inspection of the new route from Mansfield to Sutton-in-Ashfield was fixed for the 19th inst.

Luton.—At the next meeting of the Council the report of the Tramways Committee with regard to the trams will be presented.

Lambeth.—A town's meeting, recently held, passed a resolution in favour of the London County Council providing tramway services over the bridges.

Torquay.—The first section of the tramlines, over a mile in length, is almost completed. No more roadway will be opened until after the Christmas holidays.

Bexley.—The District Council are about to confer with the Dartford Urban District Council in respect of granting the latter running powers over part of the Bexley system.

Folkestone.—The resolution of the General Purposes Committee that the Tramways Sub-Committee be limited to nine members has been confirmed by the Council.

Kingston-on-Thames.—The Board of Guardians have agreed to give up 4ft. of their workhouse frontage, about 600ft. in length, to enable the tramway company to widen their track.

Liverpool.—A deputation has waited upon the Council urging them to provide a line of trams along Edge-lane. As an alternative proposal the deputation urged the inauguration of a service of motor 'buses.

Wembley.—The question of the Middlesex County Council's tramway scheme was again considered by the Council at their meeting last week, but discussion was postponed pending the receipt of further information.

Hampton (Surrey).—The Council have resolved to appoint a deputation to confer with the London United Tramways Co. and the Board of Trade relative to the proposed widening of High-street for tramway purposes.

Glasgow.—The Town Council had before them at their last meeting a proposal for the increase in distances of ½d. fares. In opposition to the proposal it was pointed out that to do so would cost about £129,000. The proposal was defeated.

Stalybridge.—At the monthly meeting of the Town Council last week allusion was made to the faulty ventilation of the Joint Board's electric cars. The chairman of the committee undertook to bring the matter before the notice of the Board.

Leicester.—The annual supper and concert in connection with the Corporation Tramways Employés' Sick Benefit Society was held last week, and was attended by the tramways manager (Mr. A. F. Lucas) and prominent members of the Tramways Committee.

Poole.—The Railways Committee report that plans were prepared and approved by them for the extension of railway through Parkstone. Various street widenings have been proposed with a view to improving the service, and a new tramway shelter will be erected.

Newport.—The Electricity and Tramways Committee have decided to make a little improvement in the position of men who are partially employed as drivers on the trams or in the car-sheds, and they will present a recommendation to that effect to the Corporation.

Rotterdam.—Electricity as a motive power for tramcars was used for the first time in Rotterdam on Sept. 19, when the motive power of the tramline Honingerdyk-Parklaan was changed. The line runs through Rotterdam from east to west, and is 3·22 miles long.

Metropolitan Railway.—The extension of the Baker-street Station necessitated the demolition of a house once occupied by Mrs. Siddons. The railway company have allowed a commemoration tablet to be placed by the London County Council on their new building.

Norwich.—The General Purposes Committee have reported that the conveyance to the Corporation of the site at Orford-place in connection with the trams has been completed, and recommended that it be referred to the City Committee to devise a scheme for the utilisation of the site. The recommendation was adopted by the Council.

Grangemouth.—It was reported by the Law and Parliamentary Committee at the Town Council meeting that they had had a conference with representatives of the tramways company to discuss various questions arising out of the proposed construction of tramways. The company have promised to forward an advance copy of the draft order.

Rochdale.—A meeting of the Rochdale Tramways Committee was held last week to consider the agreement between the Rochdale and Heywood Town Councils in connection with the running of the tramways. A sub-committee of three was appointed with power to settle the matter. When the agreement is signed, Rochdale will have running powers to Heywood.

St. Marylebone.—The Council have passed a resolution in favour of the proposed extension of the London County Council South London tramway system over the Thames and along the Thames Embankment as a help towards the improvement of the traffic of London, subject to the widening of Blackfriars Bridge or the erection of a new bridge, as required by the House of Commons.

West Ham.—The chairman of the Electric Light and Tramways Committee of the West Ham Corporation replies in the local Press to some criticisms made at a public meeting respecting the finance of the tramways. He denies that the £7,000 grant to the rates was derivable entirely from horse cars, and points out that the summer receipts for 1905 were a distinct improvement on the satisfactory receipts for the summer of 1904.

Johnstone.—Representations have been repeatedly made by the Council to induce the tramway company to continue the tramway line from the present terminus to the boundary of the burgh, which is at least half a mile in length. The officials have expressed their desire to meet the wishes of the Council as far as possible, and we understand they were quite willing to construct a single line from the Cross at Johnstone to the burgh boundary.

Camberwell.—The London County Council have informed the Borough Council that, as it does not appear that it will be practicable to use any portion of the London, Camberwell, and Dulwich tramway lines, the Highways Committee propose to recommend the formal abandonment of the lines, but before doing so they ask whether the Borough Council will be prepared to carry out the work of removal subject to the Borough Council retaining all the materials removed.

Hythe.—The Town Council have held another meeting for the purpose of interviewing representatives of the two companies competing for the privilege of securing the rights to run the trams between Folkestone and Hythe. After a lengthy deliberation the matter was deferred. A public meeting of the ratepayers favoured the National Electric Construction Co.'s scheme, which took its lines through the High-street, and another line along the sea-front. Mr. Sellon in his scheme opened up a new route through Hythe on to Dymchurch and Romney.

Oxford.—The amended Bill to enable the Corporation of Oxford to work and construct tramways was considered by the Council last week, and the seal affixed thereto. The Town Clerk explained that the important financial clause had now the figures inserted in it which were not in the draft Bill, as follows: (*a*) for and in respect of the reconstruction and construction of tramways as authorised by the Act, the sum of £76,228; (*b*) for and in respect of the purposes of electric equipment and other incidental expenses in connection with the tramways, the sum of £39,357; (*c*) for lands authorised to be purchased and buildings to be erected, the sum of £17,250—making altogether £132,835. Various other minor alterations were made.

Plymouth.—The new section to Pennycomequick has resulted in a failure. For the four weeks ended Dec. 9 the receipts per car mile averaged 4·13d., or about half the cost of working. It has been decided to withdraw the large cars in use to Pennycomequick and substitute demi cars. Being much smaller than the ordinary cars, the demi cars consume less current and are worked by one man, who acts both as driver and conductor. The Tramways Committee have decided to recommend the Corporation to discontinue the Union-street service. In connection with the proposed electrification of the West Hoe section, the committee are of opinion that the present was not an opportune time to incur so large a capital expenditure as would be involved, and have decided to make no change for the present.

Light Railway.—The order made by the Light Railway Commissioners, and modified and confirmed by the Board of Trade, authorising the construction of a light railway from Hope Station (Midland Railway Co.'s Dore and Chinley branch) to Bradwell and Castleton, has been issued. The line is to be nearly three miles in length, and is to be constructed on a gauge of 4ft. 8½in., the motive power being steam, electricity, or such other as the Board of Trade may approve. If the railway is not completed within five years, the powers granted to the company will lapse, except as to the part then completed. The speed is not to be more than 25 miles an hour, and at certain points 10 miles an hour. The maximum charges for passenger traffic are to be 3d., 2d., and 1d. per mile for first, second, and third classes respectively.

Paris.—The navvies and labourers who are employed on the Metropolitan Underground Railway are up in arms against the contractors and engineers of the underground line, whom they openly accuse of purposely botching or of inadequately completing the tunnels, thereby endangering the public safety. They tried to force their way into the chamber where the municipal councillors were holding a meeting the other day. The councillors have adopted a motion calling on the Prefect of the Seine to see that all the specifications and conditions of the contract for the construction of the underground line were strictly carried out. Furthermore, the prefect is to be pressed to establish responsibilities for any shortcomings in the work of the underground line, and to deal rigorously with persons not carrying out in a proper manner the conditions of the contract.

Portsmouth.—At the last meeting of the Town Council, a report was presented by the Tramways Committee recommending the provision of additional plant for working the tramways. In consequence of the increase of car mileage run, the reserve plant has had to be utilised for daily operation of the system. The committee recommend the immediate installation of sufficient plant to act as proper reserve. Sixteen extra cars are required to be operated on the existing lines to deal with the summer traffic. The additional plant will be capable of operating an additional 25 cars should any extension be decided upon by the Council. The estimated cost of the work is as follows: engine, generator, boiler, feed pumps, economiser, condensing plant, alterations and additions to switchboard, sinking well, laying negative return feeder, and providing 16 double-decked cars, £29,800. The proposals were adopted by the Council.

Dundee.—The Board of Trade inspection of the Dundee and Monifieth route was carried out last week, and everything worked smoothly and to the satisfaction of the inspector. The question of extending the lines down Union-street to Tay Bridge Station was introduced at the last meeting of the Tramways Committee. Further improvements on the system, the desirableness of which was urged, were the doubling of the line at various points, notably at Cherryfield and at Tay-street. The committee deferred consideration till a future meeting. Concerning the proposed extension along Arbroath-road to the city boundary, it was suggested that the work should be carried on by Corporation employés. The borough engineer and the tramways manager were instructed to prepare specifications for the work of the permanent way, and the electrical engineer concerning the overhead

Digitized by Google

equipment. The manager was authorised to put additional cars on the Constitution-road and Perth-road sections to meet the requirements of an increased service.

Bury.—A special meeting of the Town Council was recently held, at which a motion was carried authorising the promotion of a Bill in the next session of Parliament. The Bill provides for an extension of the system along various sections. It was urged by Colonel Hall, the proposer of the motion, that the earnings would amount to 9½d. per car mile, which was sufficient to meet all expenses. It was also stated that the tramways undertaking was improving, and it was hoped that the Council would be able to go in for powers to link up with Bolton. Referring to the proposed extension of the car-shed, Colonel Hall remarked that whether they extended the car-shed or not they would have to provide a series of workrooms in which to carry out repairs and do other work. The cost for that would be £4,400. If they extended the car-shed over about one-third of the vacant land they now had, they would provide accommodation for 27 small cars and 18 large ones, and the inclusive cost of that and the workshops would be about £8,451. As to the workshops, the committee had decided to provide those.

Ilford.—We have received a statement of accounts of the tramways fund of the Urban District Council for year ended March 31, 1905, from which we see that the gross revenue amounted to about £23,574 (or 10·09d. per car mile), against a total expenditure of £14,288 (or 6·12d. per car mile), leaving a balance of £9,286, which is equivalent to an average of 3·97d. per car mile. The bulk of the income (about £22,719) was derived from the sale of car tickets, while the chief items of expenditure were made up as follows: traffic expenses, £6,892; general expenses, £1,888; maintenance, £1,825; power expenses, £3,629. Interest on mortgage debt to the extent of £4,419 was paid during the year, together with £3,098 as instalments of principal of money borrowed. The total track mileage is over 11 miles; the number of car miles covered during the year was 560,971, over which 5,584,901 passengers were carried at an expense of 530,605 units, which, per car mile, was 1·03 units. The number of cars in stock is 22, and the average in use per 14½-hour day was 14. The average fare per car mile was ·74d., and that per passenger ·99d. The number of passengers per car mile averaged 9·95, and the number of journeys per head of the population was 3·93.

Huddersfield.—The motormen and conductors of the Huddersfield tramways have handed in their notices to cease work unless certain alleged grievances of which they complain are remedied. The chief of these appear to be suspensions and dismissals without sufficient cause. Further, the men state that for six months they have been trying to get alterations made in the rules relating to the use of the brakes, but have not been able to get an interview with the committee. A strike was, however, averted, and representatives of the men's union have been asked to meet representatives of the Council. The Corporation on Wednesday considered recommendations of the Tramways Committee to agree to transfer to the National Electric Construction Co. the powers of the Corporation to construct so much of the tramway from Halifax to Huddersfield as lies without the borough of Huddersfield, or such of those powers as are necessary for the promoters. The following conditions govern the transfer: the company to pay the Corporation the costs (£855. 6s.) incurred in obtaining the powers for the Brighouse and Rastrick line, to satisfy the Corporation of their intention to construct the tramway within a reasonable time after the company obtain powers, and to execute an agreement accordingly. The General Purposes Committee, having considered these resolutions, recommend that the Corporation agree (subject to approval of the Board of Trade and all necessary authorities) to grant running powers to the promoters, on terms satisfactory to the Corporation, over the line of the Corporation between Ashbrow and the centre of the town. The Tramways Committee had previously decided that they could not see their way to agree to grant running powers.

Wandsworth.—On the subject of the proposed continuation of the tramway from the present terminus in Streatham High-road to the county boundary at Norbury, the Improvements Committee of the London County Council state that, after careful review of all the facts, they adhere to the opinion that the scheme now suggested for widening the thoroughfare is preferable to the one proposed in 1902, and that they do not see their way to advise the County Council to depart from its decision. They asked that the matter may be again considered by the Council with the view to its agreeing to consent to the construction of the proposed tramway, and to contribute one-third of the net cost of the improvement shown on the plan accompanying the letter from the County Council on July 31 last. The General Purposes Committee, however, recommend the Borough Council to adhere to its resolution objecting to the scheme of the London County Council. The Streatham Tradesmen's Association have forwarded a letter to the Borough Council expressing a hope that they will persist in their objection to the London County Council's proposed diversion. In connection with the London County Council's proposed construction of a tramway from Clapham to Lavender-hill, the Highways Committee of the Borough Council have recommended that the County Council be informed that they would be prepared to consent to the introduction of the proposed Bill upon the conditions that the London County Council pave with wood the whole width of the carriageway of the part of North-side, Clapham Common, in which the tramway would be laid; that they construct a surface-water sewer along Long-road, of which the Borough Council would pay one-third of the cost; and that they reconstruct as a double line and electrify the existing tramways from the junction of Cedars-road and Lavender-hill to East-Hill, Wandsworth, as soon as possible.

London County Council.—The Highways Committee recommend that the tender, amounting to £46,490, of Messrs. E. C. and G. Keay for the erection of steelwork for the second portion of the Greenwich generating station be accepted. The Highways Committee ask for a vote of £3,560 with which to commence the tramway subway service, beginning with a four-minute service of cars. The same committee recommended that the offer of J. Mowlem and Co. to execute for a sum of £20 872 the roadwork and platelaying in connection with the reconstruction of the existing tramways in Vauxhall Bridge-road, between Victoria Station and Vauxhall Bridge, for the underground conduit system of electric traction, be accepted. The committee further recommended that the British Westinghouse Electric and Manufacturing Co. be allowed to sublet to the undermentioned firms (or to such other persons or firms as may be approved by the Council's chief officer of tramways) the following portions of the work included in the company's contract for the supply of 34 tramcar trucks and electrical equipments—namely: (1) the manufacture of the trucks to Messrs. Mountain and Gibson, of Bury, and (2) to Messrs. A. Reyrolle and Co., of Hebburn-on-Tyne, for the manufacture of the plugs for car ploughs. The Council have adopted the recommendation of the Highways Committee for the expenditure of capital sums of £186,000 to cover the cost of the erection of the second portion of the Greenwich electricity generating station and sub-station, and of £250,500 for the provision of the plant, machinery, and other equipment of the station. Colonel Yorke, on behalf of the Board of Trade, has inspected the length of tramway which has been constructed from the Highgate Archway to the Archway Tavern, to link up the systems of the Middlesex and London County Councils. Sir Francis Cory-Wright, chairman of the Highways Committee of the first-mentioned, was also present. This short length has been made by the latter on the overhead electric system, but, until their own lines have been electrified, will be leased to the Metropolitan Electric Company, and worked by them in continuation of the route from Whetstone to the Archway, which they already lease from Middlesex. The new line opens for public traffic this morning. At Greenwich on Wednesday, R. Craker, a London County Council tramcar driver, was summoned for exceeding the speed of 12 miles an hour between Canal Bridge and the Greenwich borough boundary. The defendant said he had been driving only a fortnight and did not know the speed at which he was travelling. The magistrate said the rate of speed was dangerous, and fined the defendant £5 and 2s. costs.

LIGHTING AND GENERAL.

Street.—Plans for the proposed telephone poles, etc., in the district have been approved.

Rathdown.—The Guardians have decided to light the workhouse, etc., by electricity at a cost of £2,800.

Lewisham.—The Postmaster-General has obtained permission to lay underground telegraph lines along Stanstead-road.

Llanelly.—An inquiry is to be held into the application of the Town Council for a loan in connection with the electric lighting.

Worthing.—The Council have now decided to raise a loan for electricity extensions, sanction to which has already been obtained.

Pontypridd.—Tenders are required for the construction of a reservoir for the purpose of condensing works for the electric generating station.

Salford.—We understand that the Corporation's offer for lighting a number of streets in Prestwich is being favourably considered by the Urban District Council.

Glasgow.—We noted last week the proposal to borrow £240,000 for electric plant, and it is estimated that an additional £35,000 will be required for mains and buildings.

Christmas Cards.—We are pleased to acknowledge receipt of illustrated greetings from the engineer and staff of the electricity department of the Leek Urban District Council.

Brent.—The Parish Council have unanimously agreed to accept the Postmaster-General's terms to establish a call office at Brent Post Office in connection with the trunk telephone system.

Beverley.—The application of the Town Council to the Board of Trade for permission to let the electric lighting order stand good until some *bona fide* application was made for its revocation has been refused.

Whitehaven.—The Lowca Engineering Co. are contemplating an extension of plant which might include a scheme for the lighting of Parton by electricity. The matter has been referred to the Parochial Committee.

Calcutta Electric Supply Co.—The number of units delivered to consumers during the four weeks ended Nov. 24, 1905, were 263,852 compared with 176,897 units in the corresponding four weeks of the preceding year.

Portsmouth.—The construction of an inlet in the sea-wall at the tidal basin of Portsmouth Dockyard for the pipes that are to convey the sea-water to the condensers at the new electric power station has been completed.

National Electrical Manufacturers' Association.—At a meeting of conduit tube manufacturers on Dec. 18 it was decided, owing to the rise in the price of raw material, to raise prices 5 per cent. on the net as from Dec. 20.

Chichester.—We understand that the provisional order for electric light has been transferred to Mr. Boot, electrical engineer of Tunbridge Wells, who is to pay the Council £500 for the transfer, and to proceed with the formation of a company at once.

London County Council.—On Tuesday it was agreed to lend the Fulham Council £25,000 for electric lighting purposes. Sanction was also given to the borrowing by the Stoke Newington Borough Council of £18,020 and £5,800 for provision of a dust destructor.

South Metropolitan Electric Light and Power Co.—The final instalment upon the ordinary and preference shares and debenture stock, issued under the circular dated June 23, 1905, falls due on the 1st prox., and the notices have been sent to the shareholders.

Digitized by Google

Bridgend.—Arc lamps are coming into use here for the lighting of shop fronts, the current for which will be charged at the rate of 3½d. per unit. A reduction is being made to all consumers from 4½d. to 4¼d. per unit and 4d. per unit to all consumers of over 200 units per quarter.

On the Telephone.—Messrs. Johnson and Phillips, Old Charlton, inform us that they have arranged a new telephone system with the General Post Office to their works at Old Charlton. The telephone number is "75 Central," and they have three direct lines from the London exchange.

Christmas Souvenir.—W. T. Glover and Co., Trafford Park, are issuing a novel pipe cleaner, with wings inscribed "Glover's Cables," and they draw attention to the fact by a card inscribed as follows: "We trust that (with pipe free from nicotine stings) you'll notice the message displayed on the wings."

Methyen.—The National Telephone Co. are about to open a telephone office here. It is understood that communication will be given through an exchange office with Crieff, Perth, Scone, Bridge of Earn, etc., and that a further extension will be made to Glenalmond College, Logiealmond, and Kipney through the Glen of Dumtochty.

Stoke-on-Trent.—The electrical engineer in his monthly report states that at the end of last month the works were supplying 158 consumers, representing a total of 10,558 8 c.p. lamps. The negotiations between the electrical engineer and Mr. Tabbinor for a supply of electricity to houses in Shelton New-road have been completed.

Blackpool.—The Electricity Committee recommend that application be made for sanction to the borrowing of £4 000, repayable in 30 years, for cables, transformers, and other materials for extensions of the electricity mains in Raikes-road, Whitegate-drive, Raikes-parade, Palatine-road, Bloomfield-road, and for main extensions for new prospective consumers.

Newcastle.—The Watch Committee have issued their report upon the proposal that certain streets in the city be lighted by electricity. The committee, after considering the merits of gas v. electricity, recommend that the City Council apply for a loan of £4 500 to defray the necessary capital expenditure for lighting the proposed streets by 180 electric lamps of 700 c.p. each.

Coventry.—Application is to be made for sanction to the borrowing of a further £5,000 for the purchase of electric motors to be let out on hire. Alderman West, chairman of the Electric Light Committee, on Tuesday showed that a previous investment of £7,000 for similar purposes is earning about 12 per cent. interest by the hire of the motors, while the interest and sinking fund expenses represented a charge of only 6 per cent.

Telephones to the Continent.—The Chambers of Commerce Association, recently addressed a letter to the Postmaster-General on the subject of telephonic communication with the Continent. A reply has been received stating that no definite information was available as to the limits of distance by sea and land over which telephonic conversation could take place, and that the limit had to be determined by practical experiment in each case.

Grimsby.—At the last meeting of the Grimsby Chamber of Commerce and Shipping it was resolved to again approach the Postmaster-General to endeavour to obtain an all-day and all-night telegraph service for Grimsby. The secretary was instructed to inquire into the telephone service at Grimsby, and to urge that an extra trunk line should be put on to Hull, as members find the line so occupied that a great deal of time is lost in endeavouring to get through to Hull.

Brighton.—At Friday's meeting the Telephone Committee received a report from their engineer and manager stating that the whole of the authorised capital of the department had been expended, and recommending that application be made for sanction to borrow a sum of £2 000 for connecting new subscribers on to existing spare plant, pending the settlement of the negotiations now in progress with the Post Office. The committee agreed to recommend that the Council should apply for the loan.

St. Pancras.—The Borough Council propose to apply to the London County Council for sanction to a loan of £12,150 for electric lighting purposes as follows: for purchase of leasehold interests in 108 and 112, Great College-street, £1,700; for extensions of mains, services, etc., from April 1 to Sept. 30, 1905, £6,124; for extensions of mains, services, etc., from Oct. 1 to Nov. 30, 1905, £1,783; for further extensions of mains and services, feeding and supply mains in Cumberland Market district, etc., £2 543.

Hipperholme.—A circular is being posted throughout the district calling upon all ratepayers willing to take the electric light to give notice thereof at the Council offices as early as possible. Mr. T. J. Constantine, in proposing the adoption of the minutes of the committee, said they wanted to hear the voice of the ratepayers on the question of introducing electricity. It would mean an expenditure of £3 000, and to meet that outlay it would be necessary to sell 19,000 units at 5d. per unit, which worked out at £200 for interest, etc.

Removal.—The Private Wire and Telephone Installation Co. have acquired premises at 78, Queen-street, Cheapside E.C., where they have extensive showrooms well equipped with every kind of electric fittings, and facilities for charging and repairing accumulators, which will be appreciated by many motoring men who daily go to the city. It is now close on 12 years since this company commenced its operations, and owing to the increase in its business it has been compelled to remove to the City from Palmer-street, Westminster, where its offices have been for so long.

Walsall.—The last report states that the total number of consumers supplied on Nov. 30 last was 441. During the past month the total units generated at the station was 174,679. The total output from the main generators was 169,171 units. The total units from the transformers was 131,782 (estimated). The total units registered on the meters was 122 655. The machinery was run for 715 hours. The wages paid amounted to £132. A request of the Tramways Committee that the charge for current supplied for tramway purposes should be reduced from 1½d. to 1¼d. per unit has been declined.

Beckenham.—The Urban District Council have adopted the recommendation of the Electric Lighting and Tramway Committee to the effect that Mr. Angell be asked to continue his honorary services as advising engineer for a period of six months dating from Nov. 22 last, but that Mr. Tapper, the resident engineer, be directly responsible to the Council for the running and condition of the station and undertaking. The following subjects will come under the consideration of the committee at an early date—viz: free wiring to new houses, hire of motors, arc lamps, etc., differential system of charge.

London Gazette.—The partnership between G. H. Scriven and H. G. King, carrying on business as electrical and consulting engineers and dealers in patents at Craven House, Kingsway, Holborn, London, has been dissolved by mutual consent. A first and final dividend of 2s. 8¾d. in the £ has been declared in the estate of F. Shaw, electrical contractor, Hessle-road, Kingston-on-Hull. A receiving order has been made out on debtor's petition in the estate of J. R. Charnock, electrical engineer, etc., Stonegate-road, Leeds. The first meeting will be held at the official receiver's offices, 22, Park-row, Leeds, at 12.30 p.m., Dec. 29.

Paddington.—The Finance Committee of the Borough Council are of opinion that the following figures, at which the undermentioned municipal electric undertakings were assessed for rateable purposes in the recent quinquennial valuation, are inadequate: Bermondsey, £1,796; Fulham, £2,432; Hackney, £5 430; Hammersmith, £6,500; Hampstead, £13 000; Islington, £4,666; Poplar, £3,760; St. Pancras, £6 621; Shoreditch, £4.628; Stepney, £4,233; and Woolwich, £2 620. The committee recommend that the London County Council's attention be directed to these valuations of electric mains and generating stations, "with a view to such assessments being made more in accordance with the real values."

Lowestoft.—The resident engineer in his last report states that during the month two new consumers had been connected to the mains, representing 252 8-c.p. lamps. There are now connected to the mains 650 consumers, representing 32,668 8 c.p. lamps. At a recent joint meeting of the Tramways and Electric Lighting Committees the question of the charge made for current supplied to the tramways undertaking was considered, and it was resolved that, in the opinion of this joint committee, the Electric Lighting Committee should return the equivalent of ½d. per unit for all electricity used for tramway purposes for the year ending Sept. 30, 1905, and that for the year ending Sept. 30, 1906, current for tramway purposes should be charged at 2¼d. per unit. The Electric Lighting Committee have agreed to the proposal.

Cardiff.—The National Telephone Co. have asked for consent to place their wires underground. They are prepared to take the work in hand at once, and when completed the city would derive an income of about £450 per annum. A special committee has been appointed to deal with the matter. Mr. Arthur Ellis, the electrical engineer, in his last monthly report to the Electrical and Lighting Committee stated that there were 1 209 consumers connected, with a total equivalent of 144,383 lamps of 8 c.p. The total at the corresponding period of last year was 118,930, showing an increase of 21 per cent. in the total connections. The estimated revenue for the month was £664 revenue for street-lighting and £3,161 private supply, making a total of £3,826. The estimated revenue for the corresponding month of last year was £3,354, showing an increase of 18 per cent.

Awards.—We are informed that the highest award for mechanical stokers for industrial boilers, consisting of the only silver medal, has been accorded to Ed. Bennis and Co., Little Hulton, Bolton, by the Smoke Abatement Society for their mechanical stoker and self-cleaning compressed air furnace, which has obtained such splendid results over hand firing, and also over every other type of machine stoker in leading boiler-houses all over the country. Messrs. Bennis obtained at the above-mentioned exhibition a bronze medal for their new chain grate (Bennis-Miller-Bennett patent), of which a very fine model was shown, the feature of the light load damper distinguishing the chain grate evoking special interest on the part of the judges. To carry off the two highest awards for two distinct types of stokers is an honour in the receipt of which Messrs. Ed. Bennis and Co. may well feel gratified.

York.—We learn from the *Yorkshire Herald* that a serious accident has occurred at the Corporation Electricity Works, Foss Islands, York, whereby an engine driving one of the two principal dynamos for supplying electric light and power to the city was considerably damaged. There are at the works eight dynamos—four small, two medium, and two large. The last-named have been recently erected, and are very powerful. Owing to a small drain pipe of the engine driving one of the newest dynamos becoming blocked, water accumulated in the low-pressure cylinder. The engine was being started for the purpose of lighting the city, but the strain caused by the obstruction was such that the cylinder was much damaged, and the dynamo was thus put out of action. The lighting of the city was, however, not much interfered with, for ample provision had been made for stand-by plant. The other large dynamo was set in motion in a short time, and there is no reason to fear that the supply of electric light in the city will be affected. The great strain of the sudden stoppage dislocated portions of the machinery, and some parts which fell smashed some of the iron steps attached to the machinery. Fortunately, no person was near at the time. The makers of the machinery have been communicated with, and meantime some repairs have been carried out, but the dynamo is not yet in use, and will not be ready for some time. The members of the Electricity Committee have inspected the damage, which, it is feared, is considerable.

Rostrevor.—At a recent meeting of the ratepayers, Mr. J. A. Fearon (hon. secretary) read the report of the committee appointed by the ratepayers recommending that the public streets and roads leading into the village (for a distance of one-half or one-third of a mile from centre of village) be lighted with electric light—namely, one arc lamp of 1,000 c.p. in the village square, and about 18 smaller lamps on the different roads and streets leading into the village, and that the ratepayers should select a solicitor who would draw up agreements to protect the ratepayers' interests and guard against any increase being made on the rates at any future time for electric light. The meeting approved the scheme, and decided that the charge should not be more than 2d. in the £, and that this extra rate not to be extended further than the townland of Rostrevor.

Gelligaer.—The District Council have adopted a report of Messrs. Mathieson and Lloyd on the scheme for which the Council are now seeking a provisional order. Mr. Lloyd said it was questionable whether the current could be purchased from the South Wales Distribution Co. as proposed, for their mains did not run to the Gelligaer district, and it was also doubtful whether the company would run their mains to supply the Council alone. The collieries in the Council's district had their own electrical plant. In the absence of getting the current from the company there was the question as to whether they could obtain light from neighbouring collieries, and failing that, it was suggested by the engineers that a generating station be constructed at Bargoed to supply that town and Gilfach, at a cost in plant of £10,000. A provisional order and a loan of £11,000 will be applied for.

King's Lynn.—The engineer in his last report states that since the last monthly meeting applications had been received from three additional consumers for a supply of 527 additional lamps of 8 c.p., or equivalent, making a total of 22,766 from private consumers. He also reported that the walls of the engine-room were showing signs of giving way at several places, and his proposal to fix two stay-rods from end to end of the room has been approved. The following statement of figures are available: units generated, October, 1905, 49,162 (1904, 49 388); total units sold to private consumers (light and power), 25 346 (29,340); units sold at lighting rates, 17,497 (17,483); units sold at power rates, 7,849 (11,857); cost of fuel, stores, repairs, and wages at station, £131. 0s. 2d. (£142. 1s.); cost per unit generated, 0·6395d. (0 6902d.); wages of lamplighters and outside staff, £23. 18s. 11d. (£27. 11s. 10d.).

Luton.—The last report of the Electric Light and Power Committee states that since Oct. 6 last 113,256 units had been generated, an equivalent of 1,358 8 c.p. lamps and two motors of 7 h.p. connected, making a total of 286 consumers with 17,561 lamps and 100 motors of 495 h.p.; that the number of units generated showed an increase of 100 per cent. over the number generated during the corresponding period of last year; and that at the present time applications were in for over 700 additional lamps and 55 h.p. in motors. The electrical engineer has been instructed to carry out extensions of cables at an estimated expenditure of £744. It has also been resolved that the following shall be the reduced charges from March 31, 1906: lighting—6d. per unit for the first 70 hours of the minimum demand per quarter, 2d. per unit after such 70 hours, or a uniform rate of 4½. per unit; power—2d. per unit for the first 1,000 units per quarter, 1½d. per unit for the second 1,000, 1d. per unit for any amount over 2,000 units per quarter.

Glasgow Exchange Fire.—A fire occurred on the premises of the National Telephone Co., Royal Exchange-buildings, last Saturday night. The outbreak occurred in the test-room, which is situated near the roof at the south-east corner of the structure, where all the cables converge. Standing as the building does in the centre of a comparatively large square, there was little chance, owing to the slight wind which prevailed, of the flames being bodily carried to adjoining property. The one dangerous means of communication was over the numerous wires which radiate from the exchange in every direction, but the brigade effectually performed their task, and only the test-room and the wires were damaged. As soon as the exchange officials were apprised of the outbreak, emergency gangs of electricians and telephone workers were summoned from all over Scotland, England, and Ireland, even as far south as London. These men set to work immediately the flames subsided, and will be engaged without a break until the damage is repaired. It is expected, however, that communication will not be fully restored for two or three days.

Gravesend.—The Western Electric Co. have advised the Council that owing to the present abnormal prices of copper and lead they could not supply cables at existing schedule rates, but they were prepared to supply subject to an addition or deduction depending upon the market prices of copper and lead at time of ordering. A patent reversible booster is to be purchased, and the engineer is to visit two or three power stations to which reversible boosters have recently been supplied. He is also trying to ascertain by experiment if sufficient water for the new condensers is available from a shallow subsoil well. The Windmill-street type of lantern fitted with tantalum lamps on wall brackets is to be used for West-street lighting. The engineer has been directed to report at the next meeting *re* wiring. The lighting of Upper Wrotham-road from Woodlands to Cross-lane by electric light will come before the next meeting of the Town Council. The chairman of the Electric Committee and the engineer are to attend the annual conference of the Incorporated Municipal Electrical Association, and the Local Government Board will be asked to allow the expenses of delegates attending those conferences in the same way as are the expenses of delegates attending the meetings of the Urban District Councils' Association.

Stepney.—The Council propose to obtain a *locus standi* for the purpose of opposing the preambles of all Electricity Supply Bills in the ensuing session of Parliament which affect the borough, and for the purpose of obtaining the insertion of such clauses therein as the Council may consider necessary for safeguarding the interests of the ratepayers. Mains in Tenter-street South are to be extended. It is proposed that the resolution passed by the Council on May 25, 1904—namely: "That the charge for lighting, as and from June 1 next, at the rate of 8d. per unit for the first 30 hours' use of the maximum demand during each of the six months ending March, and for the first 20 hours' use during each of the six months ending September, and 1d. per unit for all further consumption in each month, any resolution or other act of the Council or their predecessors to the contrary notwithstanding"—be (as and from Oct. 1, 1905) modified to the following extent—namely: "(*a*) That to any consumer whose total accounts, calculated on the undermentioned rates for any half-year ending June 30 and Dec. 31, reach £60 or over, or who is willing to guarantee this amount as a minimum payment for each such period, the charge for current for lighting purposes shall be 6d. per unit for the first 30 hours' use of the maximum demand during each of the six months ending March, and for the first 20 hours' use during each of the six months ending September, and ·9d. per unit for all further consumption in each month; and (*b*) that in calculating the total amount of a consumer's half-yearly bill for the purpose of arriving at the minimum mentioned in (*a*), the accounts for lighting, power, and other purposes on the same or different premises be added together." This is subject to the provision that where the accounts of various premises are so added together the average half-yearly account per service shall not be less than £15.

Bury.—The Bury and District Chamber of Commerce, having called the attention of the Postmaster-General to the charge for trunk calls between Bury and Bradford (Yorks) as compared with those between Rawtenstall and Bradford, and also to a statement that the charge for a call between Bury and Whitefield was 6d., a reply has been received containing the following statement: "The charges are calculated upon the distance by direct measurement between the towns into which trunk wires lead. The scale of charges, which under the regulations have received statutory authority, is as follows: 25 miles or under 3d. for three minutes, 50 miles 6d., 75 miles 9d., 100 miles 1s. For every additional 40 miles or fraction of 40 miles 6d. The Chamber of Commerce are doubtless aware that certain areas have been assigned to the National Telephone Co. for their local exchange system, and that trunk wires provided by the Post Office connect these areas. Rawtenstall is on the company's exchange system, of which Bacup is the trunk centre, and as Bacup is less than 25 miles from Bradford, the charge for a trunk call between Bradford and any place in the Bacup area, which includes Rawtenstall, is 3d. Bury, on the other hand, is more than 25 miles from Bradford, and the proper charge for a call between the two places is 6d. Whitefield is in the Telephone Company's Manchester exchange area, and the trunk fee for a call between Whitefield and Bury is 3d. only. In stating that the fee is 6d., possibly the Chamber of Commerce have in mind the charge made to a caller at a call office on the company's system, as it is understood that in addition to the trunk charge due to the Post Office the company charge 3d. for the use of their call office in making the trunk call. The Postmaster-General does not think the prescribed charges are excessive, and fears he cannot hold out any hope of their reduction. He is also, of course, unable to grant a special reduction in the cost of calls between Bury and Bradford." It has been decided to point out that no charge is made to subscribers for calls between Bury and Radcliffe or Ramsbottom, that Whitefield is as near to Bury as each of these places, and suggesting that Whitefield should be included in the Bury area.

Bermondsey.—When the auditor of the Local Government Board, Mr. H. Carton Roberts, attended at the town hall on Tuesday to audit the accounts of the Electric Lighting Committee for the year ended March 31, 1905, there was considerable opposition by the Bermondsey Municipal Association on behalf of the ratepayers. The discussion centred largely upon the fact that the electric generating station and the dust destructor are under the management of the same committee, and essentially connected with each other in running the electric light scheme. The recent committee of inquiry held that it would be manifestly unfair to charge against the electric lighting the cost of dealing with the dust and refuse or any losses connected with the destructor machinery. As, however, the destructor was installed in conjunction with the electric generating station, and is used to supply steam to it, the Municipal Association maintain that the charges for the destructor, after making allowance for any saving which it may bring about, should be considered jointly with the electric lighting undertaking. The cost of working and maintenance of the destructor for the year proved to be £5,675. The revenue, which included £500 credited to the destructor for electricity on account of its steam supply, amounted in all to nearly £887. The actual cost of the destructor for the year was, therefore, £4,788 odd. Some 13,027 tons of refuse were dealt with, which, if carried away by barges in the old way, would have cost £1,302. The realised loss for the year on the destructor was, therefore, £3 486. In the matter of disposal of refuse, the cost per ton with the destructor thus works out to 7s. 4d. per ton. The Municipal Association also objected to electric lighting debits being transferred to another account, whereby the electricity undertaking was made to appear in an unduly favourable light. It was pointed out that the accounts showed a surplus of £1,000, which the Municipal Association contended was brought about by charging to other accounts expenses which really ought to be borne by the electric lighting undertaking. They contended that the sale of current to private consumers resulted in a loss of £308. The declared profit of £1,000 was brought about by the following means: During the year 387,480 Board of Trade units were generated for municipal purposes. The cost of producing this amount of current was £3,591. 10s. 9d., while the ratepayers paid £5,039. 4s. 6½d. for it as follows: for lighting municipal institutions, £1,535. 11s. 0½d.; and for public lighting, £3,505. 13s. 6d. Deducting the loss on sale to private consumers of £308. 3s. and other items amount-

Digitized by Google

ing to £139. 10s. 9½d., the profit of £1,000 is left—that is, the profit in question has been made by placing an undue charge upon the undertakings which are maintained by the rates, or, in other words, imposing an excessive charge on the ratepayers so as to show a surplus on the year's working. The auditor will give his decision in the course of the next two or three weeks.

Dundee—Mr. Harry Richardson, the city electrical engineer, has presented to the City Council a report in which he deals with the present position and prospects of the electricity undertaking, and with the outlines of the scheme for a new generating station at Stannergate, the estimated cost of which is £75,000, exclusive of the price of land. Mr. Richardson says that the question of extending the undertaking is not debatable, as they had a maximum load of about 2,500 kw., while the capacity of the present plant under favourable conditions did not exceed 2,700 kw. He suggests that one of the two following courses be taken: (1) putting down more plant in the present station and more low-tension feeders over the present area; (2) putting down a new station and generating three-phase alternating current at a high pressure, and distributing with but little loss to small sub-stations in the different districts, and from these sub-stations supplying the surrounding districts at low-pressure current, as at present distributed, thereby not affecting the consumers by any change of their conditions, except that they get a more satisfactory supply. The following is an approximate estimate of the cost of extending the present station: engine and dynamos, £11,000; boilers, £3,500; mains, £5,800; three complete sets of superheaters, £650; three sets of mechanical stokers, £680; one complete condenser, £700; air-pumps, £500; circulating pumps, £120; two sets of feed pumps, £400; feed-water purifier, £400; feed-water heater, £320; new cooling tower, £900; batteries, etc., £900—total, £25,770. Mr. Richardson considers it almost impossible to put anything else on the present site than a turbine, owing to the very limited space and the power required. Experience pointed to the fact that there was trouble in generating continuous current with a high-speed turbine, while there was none in generating alternating current with the same means. Boiler space might be found, but the chimney and main flue were not large enough by any means for the present station. The cables were overloaded also, and in spite of the careful rearrangement of distribution with a view to saving the loss between the station and the consumers, this still amounted to 17 per cent. In other words, the low-tension system of distribution in towns or areas having above a certain demand gave a very poor elasticity of extension with reasonable expenditure. Mr. Richardson does not recommend the adoption of the extension scheme, but is in favour of the building of a new station and of starting a new policy of distributing at high pressure. He quotes figures showing that Dundee, which received from its consumers only 2·17d. per unit, had spent considerably less per head of population than many other towns on their electricity undertaking. The ratio of Dundee is £1, as compared with £1. 4s. in Aberdeen. He mentions that the cost to the town of the present station, exclusive of cables, was as follows: buildings, lands, and works, £19,913; machinery and dynamos, £63,677; batteries, £2,882; electrical instruments, £1,747; general apparatus, £1,026; office furnishings and fittings, £524—total, £89,769.

PROVISIONAL PATENTS, 1905.

DEC. 11.

14889A. Improvements in the method of insulating electric wires or cables. Paolo Coridori, 31, Bedford-street, Strand, London. (Date applied for under Rule 5 of the Patents Rules, 1905, July 19, 1905.) (Complete specification.)

25684. Improvements in electrical conduit fittings. William Winstanley Strode and Horace Foster Richens, 48, Osnaburgh-street, London.

25687. Improvements in conduits for electric conductors, pipes, and the like. John Henry Harradine, John Thomas Biddle, and Lorenzo William Crosta, Temple-buildings, Albert-street, Nottingham.

25702. Improvements in electrical resistances. John Henry Holmes, Queen Anne's-chambers, Westminster, London. (Complete specification.)

25729. An improved automatic earthing device and cut-out for the overhead conductors of electric railways. William Edward Thomson and Charles Benjamin Pinkerton, 11, Southampton-buildings, Chancery-lane, London.

25748. Improved magnetic separator. William Simpkin and James Bain Ballantine, 23, Southampton-buildings, Chancery-lane, London.

25754. Improvements in or relating to wave telegraphy. Alfred Julius Boult, 111, Hatton-garden, London. (Ferdinando Lori and Marquis Luigi Solai, Italy.)

25759. Improvements in or relating to protective devices for the frames or stators of electric machines. Coleman de Kando, 111, Hatton-garden, London. (Complete specification.)

25768. Improvements in means for insulating electric wires or cables. Paolo Coridori, 31, Bedford-street, Strand, London. (Complete specification.)

25771. Improvements in electric transformer furnaces. Otto Frick, 322, High Holborn, London.

DEC. 12.

25802. An improved electrical terminal attachment device. Stephen James Murphy, 10, St. George's-crescent, Liverpool.

25811. Improvements applicable to trolley standards for electric cars. John Aldworth, Lorenzo William Crosta, and William Boot, Temple-buildings, Albert-street, Nottingham.

25826. Improvements in and relating to means for automatically collecting up the subscribers of telephone exchanges to each other. Josef Peticky, Ivan Cizek, and Franz Suchanek, 72, Cannon-street, London. (Complete specification.)

25840. A new or improved means for conducting electric currents. Ferdinand Blaschke, 9, Warwick-court, Gray's Inn, London.

25855 Improvements in and relating to radiators for use with electricity, oil, gas, or other heating agent. Lester Betts and the Improved Electric Supplies Company, Limited, 1, Queen Victoria-street, London.

25858. Improvements relating to rail bonds for electric railways. Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (The American Steel and Wire Company, United States.) (Complete specification.)

25866. Improvements in or relating to electric telegraphy. Edward Raymond-Barker, 111, Hatton-garden, London. (Complete specification.)

25880. Improvements in electricity meters for alternating currents. Llewellyn Rolls Lester and the Rochdale Electric Company, Limited, Norfolk House, Norfolk-street, Strand, London.

DEC. 13.

1482A. Improvements in or relating to electrical contact makers or distributors. Percy Warren Noble, 18, Hertford-street, Coventry. (Date applied for under Rule 5 of the Patents Rules, 1905, Jan. 25, 1905.)

25893. Improvements in mercury or other vapour electric lamps. Joseph Skwirsky, 36, Newman-street, Oxford-street, London.

25944. Improvements in electric arc lamps. Joseph Tollerton, 8, Quality-court, Chancery lane, London.

25952. An improved dynamo-electric generator. Parnell Rabbidge, 111, Hatton-garden, London. (Complete specification.)

25971. Improvements in or relating to electrically-lighted miners' safety and like lamps. Thomas Anthony Jones and Anthony Jones, trading as Patterson and Co., 70, Chancery-lane, London.

DEC. 14.

26032. Improvements in or relating to electric ignition systems for internal-combustion engines. John James Henry Sturmey, 18, Hertford-street, Coventry. (Charles Edgar Duryea, United States.) (Complete specification.)

26046. Improvements in or relating to electric clocks. Conrad Hubert, 111, Hatton-garden, London. (Complete specification.)

26052. Improvements in or relating to apparatus for storing and paying out lengths of conductors or wires connected to electric instruments or apparatus. René François Joseph Samuel Baron, 111, Hatton-garden, London. (Complete specification.)

26066. Improvements in coin-freed electricity meters. John Mesny Tourtel, 146A, Queen Victoria-street, London.

26072. Improvements in telegraphs for transmitting orders. Siemens und Halske Akt.-Ges., Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 14, 1904, being date of application in Germany.) (Complete specification.)

26081. Improvements in or relating to tremblers for induction coils. Charles Henry Bryant and Francis Leslie Matthew Forster, 111, Hatton-garden, London.

26086. Improvements in arc lamps. Hermann Max Körting, 31, Bedford-street, Strand, London. (Complete specification.)

26089. Improvements in and relating to alternating-current dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26090. Improvements in and relating to dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26091. Improvements in and relating to alternating current dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26092. Improvements in and relating to alternating-current dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26093. Improvements in and relating to dynamo-electric machines. The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

26094. Improvements in and relating to the alternating-current dynamo-electric machines. Allgemeine Elektricitäts-Ges., 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 15, 1904, being date of application in Germany.) (Complete specification.)

Digitized by Google

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Jan. 4.

1904.

27168. Method of automatically regulating the voltage in electric light and power circuits with varying loads. Tilney.

27437. Arc lamps. Zingel, Wolf, and Reiner.

27859. Automatic electric cell switches. Elektricität's Akt. Ges. Westfalia and Kupferschlag.

28468. Systems of electric distribution and conductors therefor. Gati.

28858. Electric switch and circuit breaker. Hi·st ·nd Brook.

1905.

80. Electric arc lamps. British Thomson-Houston C.mpany, Limited. (General Electric Company.)

1638. "Party line" system of telephones. Stocks.

2401. Starting and control of direct-current electric motors Heath.

3857. Controlling devices for electric motors. Fairweather. (Diehl Manufacturing Company.)

4456. Conduits for electric conductors or cables. Devonshire.

4513. Electric clocks or the like. Chandler and Bonnikeen.

4731. Electric pushes or switches for operating electric bells, telephones, signalling, and for other purposes. Wansbrough.

4780. Appliances for testing electric batteries. Lake. (Jacobsen.)

5865. Construction of conduits for containing electric cables and wires and other wires, tubes, pipes, and the like. Hepworth-Collins.

NOTES.

Electric Railway.—It is announced that a test is to be made of the Krizik direct-current three-wire system on the Vienna Stadtbahn, which is at present operated by steam. The locomotive will contain four 200-h.p. motors, and a voltage of 3,000 volts between the outer wires will be used. The section to be equipped is that between Praterstern and Hauptzollampt, a distance of 1·4 km., or a little over one mile.

Obituary.—We greatly regret to learn of the death of Mr. Charles Ravell Bellamy, who for some years had acted as general manager of the Liverpool electric tramways. Mr. Bellamy died at Liverpool on Saturday at the age of 50 from the rupture of an artery following a sprained ankle. When the Liverpool electric trams commenced in 1898 Mr. Bellamy was appointed general manager, and he had brought that system to its present high state of efficiency. The undertaking last year carried 116,642,663 passengers, and had a gross income of £547,624. Mr. Bellamy took an active interest in electric traction, and was prominent in several movements organised to benefit the industry.

Books Received.—We have received from the British Electric Transformer Company, Limited, of Hayes, Middlesex, a handsome copy of Whitaker's Almanac for 1906, bound in padded leather. Besides the storehouse of valuable information for which Whitaker's annuals are noted, a number of supplementary pages are inserted in the beginning of the book containing a list of officials and councils of the Institutions of Civil, Mechanical, and Electrical Engineers. There is contained also the names of some well-known customers of the British Electric Transformer Company, Limited, together with charts and statistics showing the development and present extent of the company's business.

New Publications.—We have received the December issue of the *Bulletin* of the Société Belge d'Electriciens, which opens with an account of the monument erected at Liége in memory of Zénobe Gramme, together with the reproduction *in extenso* of the addresses delivered on the occasion by MM. Emile Glosset and Emile Javaux. The latter's discourse revealed for the first time the actual methods followed by Gramme in the design of his dynamos. Other contributions are "A Report on the Mechanical Traction of Boats," as presented to the Congress of Navigation at Milan; "A Speed Indicator," by M. J. Garlier, and a further description of the electrical section of the Liége exhibition. The *Bulletin* for October of the Société des Ingénieurs Civils de France contains a number of interesting *mémoires* and a summary of the meetings of Oct. 6 and 14. The December number of the *Rhodesia Review* is one of general interest, but more particularly to settlers and shareholders in the many Rhodesian companies.

Heat Economy in Factories.—At an ordinary meeting of the Institution of Civil Engineers held on Dec. 19 a paper was read by Mr. H. A. Mavor, M.I.C.E., on "Heat Economy in Factories." He remarked that in an investigation undertaken in 1898 on the comparative costs of power in factories in the United Kingdom, he found great difficulty in obtaining accurate data, owing in many cases to the fact that the fuel consumed was applied for heating as well as for power. This circumstance appeared to offer inducements for further examination of the question, and his paper was an account of a method of inquiry which has resulted in a simplification of the problem and in the acquisition of useful results. The method consists in dealing with the heat production and distribution by a system of double-entry accounts, in which the boilers are debited with the heat represented by the coal and credited with the heat represented by the steam. These credits are carried to the debit of accounts dealing with the various uses to which the steam is put in the factories. These accounts, again, are credited with the work performed, the balances being carried to a balancing account, which brings out the efficiency of the prime movers and separates out the useful work and the losses in such form that the losses can be divided into necessary and avoidable losses, the whole giving a comprehensive view of the conditions of efficiency in terms of British thermal units. Specimen balance-sheets were given in the paper, and he described the methods of arriving at results showing the bearing which the ascertained efficiencies have upon existing methods of working.

Lighting in Westminster.—An instance of the unreasonable attitude which at times the local authorities adopt towards private contractors is afforded by the action of the Electric Lighting Committee of the Westminster Borough Council in regard to the provision of arc lamps in the borough. The St. James's and Pall Mall Electric Light Company, Limited, have been engaged for some time in carrying out electric lighting work in the borough. The standard illumination stipulated in the contract is 900 c.p. This power the company failed to obtain, and on the fact being pointed out to them by the city engineer they proposed to increase the candle-power by raising the current supplied to each lamp. This is now being done, but until all the lamps are altered the necessary candle-power will be obtained from the remaining lamps by the method of using smaller carbons. They, therefore, asked the indulgence of the Council that, if a lamp here and there was found at times to be slightly below the standard candle-power, they may be excused for a reasonable time until they have had the opportunity to accommodate everything to the new conditions. The committee, however, relying on a clause in the contract which provides that the contractor is to forfeit as liquidated damages the sum of 5s. per lamp per day for every lamp giving less than the specified power, have refused to accommodate the company, and have recommended the Council to enforce the terms of the contract. The committee may have just cause to decline to accede to the wishes of the company, but to an outsider their action may appear somewhat arbitrary.

Fireproof Curtains.—The accident which occurred on Tuesday through the bursting of a water-main in St. Martins-lane deserves the attention of all who are dependent upon hydraulic means of operation, and especially of theatre proprietors who rely chiefly or solely upon the hydraulic operation of their fireproof drop curtains. The importance of having an electrically-operated hoisting gear in addition to the hydraulic gear was emphasised by the incident which took place at the Hippodrome Theatre when the accident occurred. The fireproof curtain is raised and lowered hydraulically, but with the failure of the water supply the apparatus was rendered impotent. It came down of its own accord, and was afterwards raised by means of an auxiliary gear. At the Coliseum very slight inconvenience was caused, as the curtain was promptly raised by means of manual assistance. This theatre, we understand, obtains its hydraulic supply through another main. The New Theatre and the Duke of York's Theatre worked their curtains by pneumatic power and counterweights respectively, so that no inconvenience was caused. Had the theatre management taken the necessary precaution to provide electric operating gear for their fireproof curtain, the possibility of any breakdown would have been avoided, because theatres are always wired for a supply from two sources, so that, if the supply from one should fail, the load can immediately be switched over to

Digitized by Google

the other. It is also to be noted that electrical control is cheaper to operate than hydraulic. The regulations of the London County Council provide that the drop curtain shall have two sets of releasing gear for each of different means.

Tramways and Light Railways.—The Board of Trade's annual return of the capital and traffic of tramways and light railways of the United Kingdom for 1904-5 shows the wonderful growth in tramway traffic since the advent of electrical traction. Comparative tables show that since the year 1878 the route length of line open for traffic increased from 269 miles to 2,117 miles, the capital expenditure from £4,207,350 to £52,675,152, the number of passengers carried from 146 millions to 2,069 millions, and the net receipts from £230,956 to £3,351,977. More instructive and interesting are the tables showing the ratio of progress represented by the "horse," "steam," and "electric" periods, the horse period being represented by the year 1879, the steam period by the year 1898, and the electric period by 1904-5. Thus we see that under the horse period the length of route open was 321·27 miles, which under the steam period increased to 1,064·19 miles, and to 2,116·78 miles after the utilisation of electric traction. Turning to the total number of passengers carried, we find the advance to be even more remarkable. In the year 1879, 150,881,515 passengers were carried, this figure rose to 858,485,542 in 1898, while the completed return for the year 1904-5 shows the huge total of 2,068,913,226. The capital expenditure per mile has increased since the days of horse traction; but, on the other hand, the percentage of net receipts to capital expenditure has increased in a rather larger proportion. The percentage of working expenditure to gross receipts from traffic shows under electric traction a marked reduction as compared with the time when steam traction was at its highest. The average fare per passenger shows a tendency to diminish, and has dropped from 1·84d. to 1·10d.

Electrolytic Purification of Water.—The growing demand for pure water on many of the American railway systems has lead to the introduction of a new process of purification which works electrically, and which, according to the *Railway and Engineering Review*, unites the advantages of efficient filtration and cheap electrolysis. The passing of hard water through the apparatus causes the precipitation of most of the mineral substances contained therein—the acidity is destroyed, and the iron is deposited at the cathode. The principal advantage which is claimed for the system, however, lies in the fact that it not only prepares good water for industrial purposes, but it prepares soft and pure water for drinking and domestic uses. The new process, instead of driving free oxygen from the water, liberates an excess of this important element, which, owing to the shape of the positive electrode, is kept in contact with the water and is eventually redissolved. This has the effect of strongly vitalising the water and at the same time sterilising it, owing to the bubbling through it of ozonised oxygen generated at the anodes. Analysis of crude polluted river water has revealed the fact that the electrical treatment entirely eliminates nitrates and nitrites which are always contained in water which has been contaminated by sewage. The apparatus consists of a cylindrical iron tank divided into two parts by a vertical partition. The anodes are baffle-shaped plates of iron, the cathode being the wall of the tank itself. By this arrangement, the hydrogen, liberated at the cathode, has free access for escape, while the oxygen, liberated at the anode, is held in confinement until enough has accumulated to overflow into the surrounding water. The solid matter is precipitated to the bottom of the tank, while the treated water overflows to the filter contained in the other half of the tank, thus making a very simple and easily transported outfit.

Rubber.—We have already drawn attention to the activity in the rubber market, and to the formation of two companies for the purpose of working rubber plantations in Liberia and Ceylon. The importance of the industry is seen by the fact that imports of rubber into Liverpool during the year 1904 amounted to nearly 402,000cwt., estimated at a value of over £6,800,000, which is only £1,000,000 less than the total value of rubber imported into the United Kingdom during that year. These figures are the highest during the last five years. From 1900 to 1902 there was a gradual decline both in the number of hundredweights imported and in their value, but an improvement set in in 1903, and continued during 1904. Most of the produce came from Brazil and West Africa, the former supplying us to the value of over £4,500,000. Notwithstanding the great improvement in the rubber industry in India, the Malay States, and Ceylon, only £900,000 worth was sent to the Colonies in 1904. We are informed that the plantation of the two species of rubber, Ceare and Hœvea, is making great progress in the Sandwich Islands, where two companies at Nahiku have already 1,250 acres with over 150,000 trees under cultivation. Climatic conditions in the Sandwich Islands, like those of Ceylon, are particularly favourable to the cultivation of these plants. The Belgian consul at Colombo reports that about 40,000 acres are consecrated to the cultivation of the Hœvea, Brasiliensis, and the Castillos. Important quantities of seeds have been exported to Malay States, Dutch Indies, Madagascar, and the English and German possessions in Africa. The latter States merit attention inasmuch as they promise to become important producers of caoutchouc, the produce amounting to 2lb. per tree in the seventh year and 6lb. in the tenth year.

Wireless Telegraphy.—This subject was treated in a paper recently read before the Glasgow Local Section by D. J. Erskine Murray, who confined himself to the consideration of typical systems of wireless telegraphy and to the recent advances made. Of the 300 British patents relating to wireless telegraphy, that which had been longest in practical use was Marconi's untuned coherer system. Untuned systems (said Dr. Murray) were being displaced by tuned systems, but their comparative simplicity and ease in working were recommendations which in many cases outweighed their disadvantages. Marconi's untuned system was mainly used for distances under 150 miles. A description of this system was given, and the methods of tuning and discrimination which depend upon the superposition of small wave motions were afterwards explained and illustrated. By the latter system interference between neighbouring instruments was prevented, and this was the system now in use for the transmission of long-distance messages. For long-distance telegraphy many improvements in methods of transmission had recently been devised, which related mainly to the production of long trains of powerful waves in the transmitter and to the use of several oscillating circuits of the same frequency coupled to one another in series in the receiver, thus obtaining a system which responded only to a wave train of exactly the same frequency. Dr. Murray claimed that the more important improvements in long-distance work were due mainly to Mr. Marconi and to Prof. Fessenden. Mr. Marconi maintained regular communication between England and Italy, a distance of about 1,000 miles, mostly overland, and had, of course, frequently achieved greater distances, including the whole width of the Atlantic. Mr. Fessenden had maintained communication over 600 miles, and was now putting up a Transatlantic

Digitized by Google

station at Machrihanish, with a receiver 420ft. high, by means of which it was hoped to communicate with the United States. The De Forest Company had also arranged to put up a Transatlantic station in Tiree.

Plastic Rail Bond.—A new permanent type of plastic rail bond which can be applied to almost any rail section, and in the use of which the angle plates are made to carry the current, was recently described in the *Street Railway Journal*. When installing the bond, a hole is drilled through the angle plate on either side of the joint between the first and second bolt holes from the end of each rail. Under each of these holes a shallow cavity running lengthwise is milled in the top of the rail base. These holes in the angle plates and the cavities underneath the rails are amalgamated by the Brown process, as is also the lower surface of the angle plate over the cavities, and both holes and cavities are filled with a new kind of plastic alloy, which does not harden or permit the liquid to run out. This material being inelastic does not jar out of the hole, and in adhering to the amalgamated rail surfaces forms a flexible conductor of low resistance between the rails and the angle plates. To prevent dirt from entering the holes, they are sealed with composition discs in such a way that they can be easily removed to allow for inspection or repair without the necessity of removing the angle plates. The latter are drilled and amalgamated before being distributed along the road for making-up the joints, the cavities being quickly milled by a portable hand milling machine. The conductivity of the joint, when the weight per yard of the two angle plates is equal to that of the rail and the rail joint is double bonded, is practically equal to that of an equal length of unbroken rail. It is claimed that the plastic alloy will always maintain contact between the rails and the angle plates and keep the conductivity of the joint unimpaired. These plastic bonds have been in service on the lines of the Denver City Tramway Company and the Rochester Railway Company for nine years, and it is stated that they are in as good condition now as when first installed.

Mica.—A report on mica, its occurrence, exploitation, and uses has been issued by the Mines Branch of the Department of the Interior (Canada). This monograph has been prepared from data and general information collected by Mr. Fritz Cirkel. The object of the inquiry was to prepare a synopsis of all that is known from a practical point of view on the subject, and to stimulate a spirit of inquiry that will lead to the development of the large mica fields in Canada, to a wider search for the mineral, and to the development of those varieties of mica which at present possess but little commercial value. The report first sets out the different species of mica, and then proceeds to describe their chemical and physical properties. The distribution of mica over the globe is very general. As a mineral of commercial value, occurring as deposits of crystals of large size, which split up easily into fine merchantable sheets, mica is found only in three countries—British India, United States, and Canada—and it is with the industry of the latter country that the report is primarily concerned. The Canadian amber variety is most extensively used for electrical insulation. The most valuable property of Canadian mica is its non-conductivity; its market value is based on its freedom from streaks and iron stains. The relamination as effected in micanite is said to improve the insulating power of the mineral. The insulating power of mica is superior to that of any other substance applicable to armatures. Of special advantages are its evenly laminated structure, which permits its ready intercalation between the copper pole-pieces of the commutator, and its hardness, which prevents it wearing away too rapidly under the action of the brushes. High temperatures have no effect upon mica, nor does colour seriously affect its utility in electrical machinery, but the presence of magnetite inclusions affecting its insulating qualities renders it useless for this purpose. In comparison with East Indian mica, the Canadian product seems to hold its own, and a phlogopite which was sent to England for testing purposes was favourably reported upon both for its general physical and chemical properties and commercial value. The report describes mica mining in many countries, contains an abstract of the mining laws of Quebec, together with a useful bibliography and index.

Electric Lighting and Power Legislation.—In view of the fact that the life of the present Parliament has been for a long time past generally surmised as uncertain, promoters have shown considerable boldness in giving notice of proposals for electric lighting and traction schemes to be brought before the forthcoming session. The number of Bills for tramways and electric railways of which notice was given last month was the same as in the preceding year—viz., 51—which is much smaller than usual. As regards London underground railway Bills, promoters seem to have abandoned their original intentions, for there is quite a number of applications for modification of powers and extension of times; while, on the other hand, only in two cases are powers sought for constructing new lines. One is the scheme for an electric railway from Hammersmith to the city of London, which is again revived, this time in enlarged form, for it is intended to construct a spur line from the main line to Bermondsey, and a spur from the main line at Haymarket to a junction with the authorised North-West London line at Edgware-road. The other scheme proposes the construction of an outer circle railway for London north of the Thames, which will connect the outlying suburbs in Middlesex and Essex. The proposal for tramways over the bridges has more likelihood of being successful now that the London County Council and the City Corporation are working together for the purpose of securing this object. Of the tramway schemes in England and Scotland generally, there is little which calls for special notice, excepting the Edinburgh Corporation's Bill, which seeks to electrify the tramways. Hitherto cable and horse tramways have held the field, but the Corporation will probably supersede these with a surface-contact system. The æsthetic tastes of the citizens have evidently not yet become reconciled to overhead wires. In the domain of Power Bills the chief interest will be centred in the attempt to capture the metropolitan area. The large number of competitive Bills points to the probability of failure in Parliament coming to a decision before the end of the session. We have already given the names of the companies who are promoting Bills, but the Administrative County of London and District Electric Power Company, whose effort to get their Bill through last year just failed at the eleventh hour, are again in the field, and will meet in the Additional Electrical Power Supply Company and the London County Council doughty antagonists. Outside of the London area the proposed Bills are not numerous, and principally seek for powers of extension.

Trade in 1905.—We have been favoured with an advance proof of Messrs. Bolling and Lowe's trade review for 1905, which is one of the first to be issued, and among the information imparted is something of interest to electrical engineers. The iron and steel trades of the Midlands and the North display great strength. As the year advanced, considerable impetus was given to them by the growing demands of shipbuilders and the requirements

Digitized by Google

of the bridge-building and structural industries. These demands were so pressing in the early autumn that prices rapidly advanced; although, singularly enough, "marked bars" did not move till November, when they rose to £8. 10s. per ton, whilst ordinary had advanced weeks before. On the Continent similar conditions prevailed. It is estimated that the British steel output will show an increase of 1,000,000 tons over last year, largely due to decreased imports. Exports here and there increased largely over 1904. In the copper market the production is increasing heavily, but not sufficiently to keep pace with the consumption. Users hold very small stocks, and the large producing mines are sold out months ahead, and are at their wits' end for metal for near delivery. A period of actual scarcity seems to have been entered upon, a scarcity which can only be accentuated if the auguries pointing to a general revival in trade prove correct. In the pig iron speculative market there was a severe squeeze in the early part of the year, which drove up prices of No. 3 Cleveland by May 14 to 55s., this price being maintained till May 19, when all the open accounts were squared off, and the cash price immediately collapsed to 45s. In July and August strong speculative buying, based upon improved reports from the home trade and abroad, initiated a fresh movement. Since then, however, the purchasing has been more or less scattered, while the attacks directed against the market have been concentrated. Which side will finally prevail cannot be estimated with any pretence to correctness at present, but ultimately improving trade must rise superior to merely temporary speculative movements. In October, hematite reached 73s. 9d, the highest figure for years. In 1902 3 the highest was 62s, and in 1904 57s. Many holders were so sanguine of higher prices that they spoke of waiting for 75s. to 80s. Much of the rise was due to speculation, but the chief demand came from the abnormal requirements of the iron and steel industries. American buying helped the situation materially. Stocks in stores are large, and this must be remembered in gauging the position. The following figures show the increases in the production in tons: Great Britain—1904, 8,563,000; 1905 (estimated), 9,500,000; increase, 1,000,000. United States—1904, 16,497,033; 1905, 22,900,000; +6,400,000. Germany—1904, 10,055,000; 1905, 10,500,000; +500,000. In September, 1904, 324 blast furnaces were working against 348 at present.

Canadian Society of Civil Engineers—In a paper read last month before the electrical section of this society, Mr. R. B. Owens gave a description of an electric accelerometer. He said the advent of the electric motor as a competitor of the steam-engine, especially in the traction field, had given rise to certain acceleration problems unfamiliar to engineers of a generation ago. At a time when the train mile was a satisfactory unit in which to reckon haulage costs, there was little occasion to bother with acceleration. Now, however, when neither the train mile, car mile, nor ton mile suffice, even when coupled with a speed factor as a basis of estimation and analysis, and when to maintain certain schedules more energy is expended in accelerating than in overcoming frictional and grade resistances, a simple, accurate, and reliable means of measuring acceleration is urgently demanded—a means at least comparable in simplicity and accuracy to those employed in the measuring of the quantities of which it is the second and first differential with respect to time. The measurement of length is familiar to all. Of practical methods of measuring velocity or speed, at least of machines, one of the most satisfactory, if not the most satisfactory, involves the use of a suitable constantly excited or permanent magnet dynamo mechanically driven by the piece whose velocity is to be measured, and electrically connected through an ammeter to a circuit of constant coefficients as shown in Fig. 1. S is the shaft whose velocity is to be measured; C is a mechanical coupler; A is the armature of a small permanent magnet or constantly excited continuous-current dynamo wound so as to have a negligible reaction within the limits of its use; R is a variable non-inductive resistance; and I is a zero centre direct-current ammeter. The reading of I will be proportional to the speed of S, and by adjusting R can be calibrated in the revolution per minute, feet per second, or miles per hour as desired. As the current through I is proportional to speed, it is only necessary to determine the rate at which the current varies in order to have a measure of acceleration. This is simply and easily done by inserting

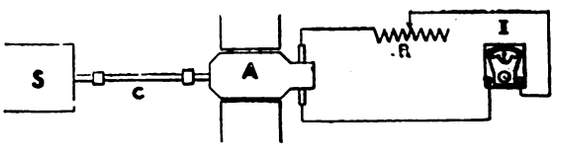

FIG. 1.

in the circuit with I a transformer, T, with its secondary connected, for purposes of adjustment, through a non-inductive resistance, R_1, to a zero centre direct-current voltmeter, V (see Fig. 2). The reading of the voltmeter, V, will then be proportional to the acceleration, positive or negative, of the shaft, S. Substituting recording instruments for the indicating ones shown, we have a recording speed indicator and a recording accelerometer. The transformer must have a straight line saturation curve and a large transformation ratio, as the secondary induced voltage is necessarily small, and the voltmeter, V, must also be sensitive. The calibration of the ammeter as a speed indicator is effected by driving the armature, A, at different constant speeds as shown by ammeter reading, and taking the revolutions in a given time by means of a revolution counter and stop watch. The calibration of the voltmeter as an accelerometer is best done by driving the armature, A, by a separately and constantly excited motor having applied to its armature, preferably of small momentum, a voltage varying approximately as a linear function of time.

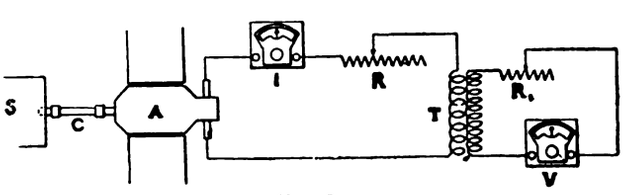

FIG. 2.

With proper manipulation of apparatus the ammeter readings plotted against time will be a straight line whose slope will be constant and equal to the acceleration and to the constant reading of the voltmeter to within a constant. In some tests made by Mr. Owen in his laboratory not long ago, A (Fig. 2) was the armature of a small low-voltage, separately excited direct-current generator; S, the shaft of a 3-h.p. separately excited direct-current motor, to whose armature by a potentiometer arrangement a steadily increasing or decreasing voltage could be applied; I and V, Weston ammeter and millivoltmeter, and T a small lighting transformer with a transformation ratio of 20; and excellent results were obtained, speed and acceleration being read to exactly the same degree of accuracy that Weston direct-current ammeters and voltmeters are capable of. With recording instruments substituted, this would seem to meet every requirement of a practical apparatus for the measurement and recording of velocity and acceleration in railway work, both steam and electric, and is applicable, of course, in many other connections.

THE STUBAI VALLEY RAILWAY.

This line was the first to be equipped for working with single-phase alternating current of high tension and frequency ($42\frac{1}{2}$). It has now been in operation some 16 months, and having regard to the decision of the L.B. and S C. Railway Company to adopt the same system, a description by Egon E. Seefehlner in our esteemed contemporary *Elektrische Bahnen u. Betriebe* is singularly opportune and interesting, more especially so in that the results of the 16 months' working are available. We are assured at the outset that both the system itself as well as the special arrangements involved have proved eminently satisfactory.

General.

The Stubai Valley Railway was first thought of many years ago, at a time when there was no practical alternative to steam working—a fact to which must be attributed the tardy fruition of the scheme. No very glowing prospect could be painted for a railway undertaking which would necessarily entail heavy capital outlay and working expenses, bearing in mind that the residential population of the valley is only 50,000, while the annual visitors to Innsbrück and neighbourhood average about 100,000. These figures constituted the sole basis for calculation, and it was early recognised that the tourist element would furnish the bulk of the passengers obtainable. Had it been a question of deciding simply which system would best meet the requirements of a traffic varying greatly in density over a given

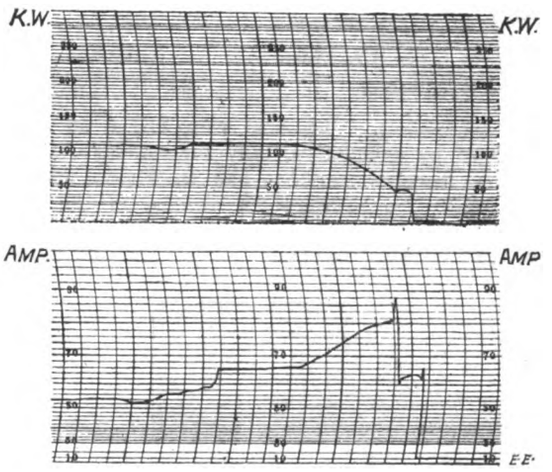

FIG. 1.—Curves for the Output and Starting Current, Stubai Valley Railway.

period, steam working would have held strong claims, but there were objections to this which could not be overlooked. It was necessary in the commercial interests of the undertaking to make the line as attractive as possible to purely pleasure seekers. Due to Tyrol's poverty in coal, steam working would also have been very expensive. The prospects of the scheme, however, at once improved when in 1902 the erection of electricity works was decided upon by the municipality of Innsbrück, in order to utilise the water power of the River Sill, and the town showed practical interest in the realisation of the railway project by making an offer to supply the necessary current for working it on favourable terms. It was then that capital was forthcoming and a start could be made with the work of construction. It was at first proposed to use continuous current, conveying it at a pressure of 600 volts to the trains by means of a third rail, in accordance with the established practice of the day. The construction of the track was commenced in the spring of 1903, the work of fixing the conductor rails and laying the feeder cables, etc., being planned for the following year. In the meantime, however, the well-known experiments with alternating current took place on the Spindlersfelde Railway. Now, the conditions obtaining in regard to the Stubai Valley project were such as promised great advantages from the direct employment of high-tension alternating current.

The direct use of single-phase alternating current of high frequency made it possible to dispense with a lot of transforming apparatus, which is both costly to purchase and to subsequently maintain. The money thus economised—the capital outlay being limited—could, it was recognised, be advantageously added to the sum set apart for rolling-stock. Thus, in place of the two-axled motorcars provided for, bogie cars could be obtained, thereby increasing the comfort of the passenger. The limited amount available for electrical equipment precluded from the outset the provision of a battery of accumulators, and in determining the size of the conductor rail the permissible minimum had to be approached. Continuous-current working in these circumstances would, therefore, have scarcely given the elasticity demanded by the character of the traffic. It would not have enabled the system to be temporarily overloaded to any required extent. On the other hand, the alternative method of direct working with high-tension alternating current enabled this requirement to be met. The overload capacity of the static transformers between the power station and conductor rail is

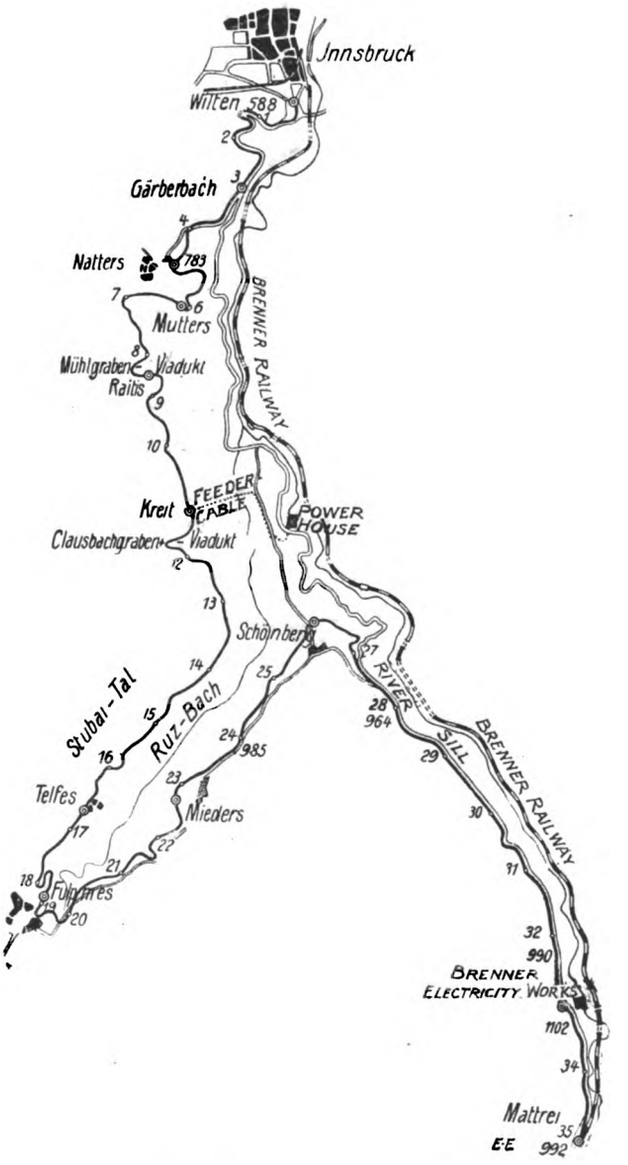

FIG. 2.—Map showing Route of the Stubai Valley Railway.

unlimited, in so far as it is confined to increased traffic during certain hours of the day. Moreover, by fixing the line tension sufficiently high, the ohmic loss in the line could also be kept within the permissible limits, even in extreme cases, without extra cost. Thus double trains may be dispatched, if required, with impunity.

There is no doubt that these advantages may also be obtained by adopting a polyphase system, but not to the same extent. Polyphase induction motors do not admit of speed control, and there is consequently no choice but to drive at the one fixed speed, thereby increasing the maximum demand so that the overload capacity of the plant is reached sooner than with the Winter-Eichberg alternating-current system of the Allgemeine Elektricitäts-Gesellschaft, which admits of the speed being reduced as

Digitized by Google

may be necessary. In the case of polyphase systems the starting currents are also much more serious than with the alternating-current system of the Allgemeine Elektricitäts-Gesellschaft. This is apparent from the curve (Fig. 1) showing the energy consumed during the starting period. The watt consumption commences at a low value, and rises gradually to the value corresponding to the tractive effort without acceleration, whereas in the case of polyphase current at the moment of starting there is a sudden rush of current, and the watt consumption sinks slowly to the level needed for the tractive effort. The employment of cascade connections to minimise this difficulty would seem to be out of the question here, since the room available on narrow-gauge rolling-stock is scarcely sufficient for the four motors which are necessary. These considerations alone justified the adoption of single-phase alternating current. The double trolley line for polyphase current would have involved greater cost—apart from any consideration of the disadvantages and complications of having duplicate collectors. Besides, the latter would have been unreliable and the maintenance cost very high on a railway possessing so many sharp curves. Indeed, champions of the polyphase system argue that the cost of doubling the trolley line is insignificant when compared with the total expenditure on electrical equipment. But this view holds, as may be easily proved by calculation, only for railways on which there is a frequent service—five to fifteen minutes—when, in fact, the rolling-stock represents the greater part of the capital outlay. Railways of this character do not, as a rule, however, serve such an extended area as to call for the use of high-tension polyphase current. Nor could the absence of commutators in the case of polyphase motors, bearing in mind all other points, turn the scale against the adoption of single-phase alternating current, since the construction of reliable and efficient commutator motors for alternating current now presents no difficulties.

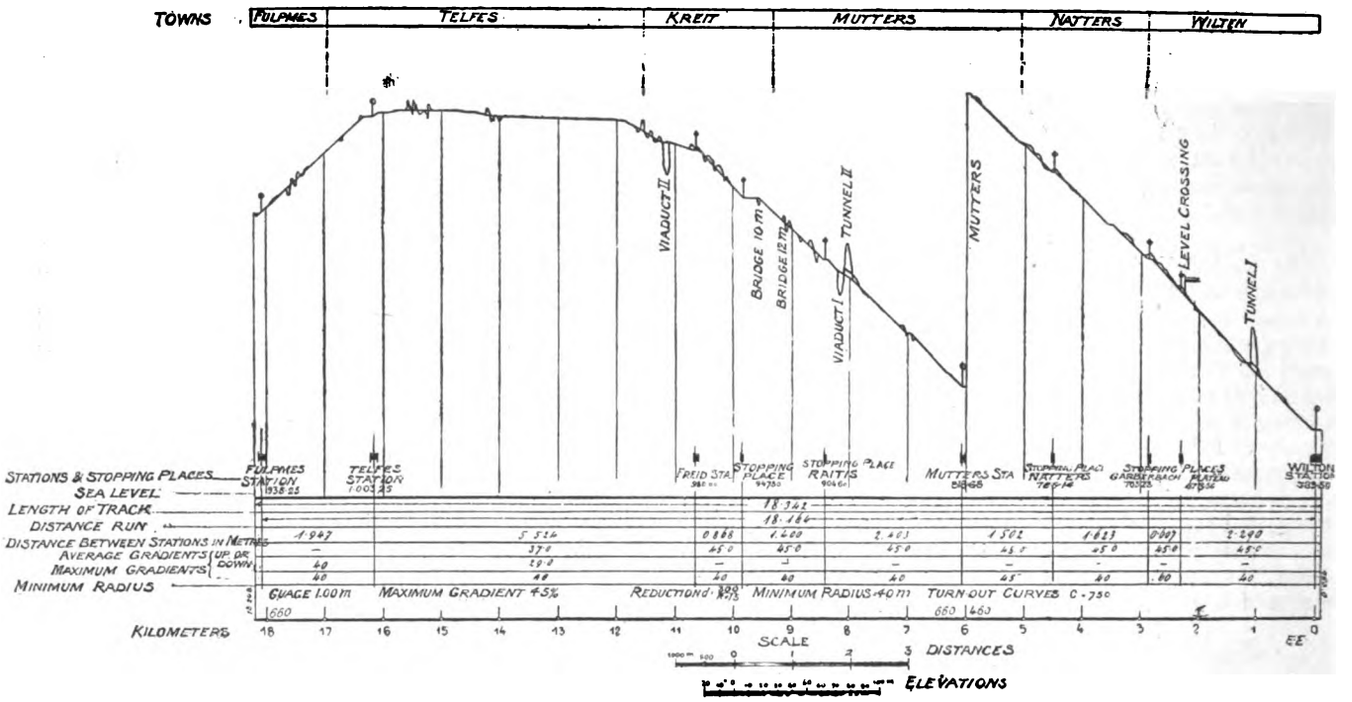

FIG. 3.—Diagram showing the Gradients, Stubai Valley Railway.

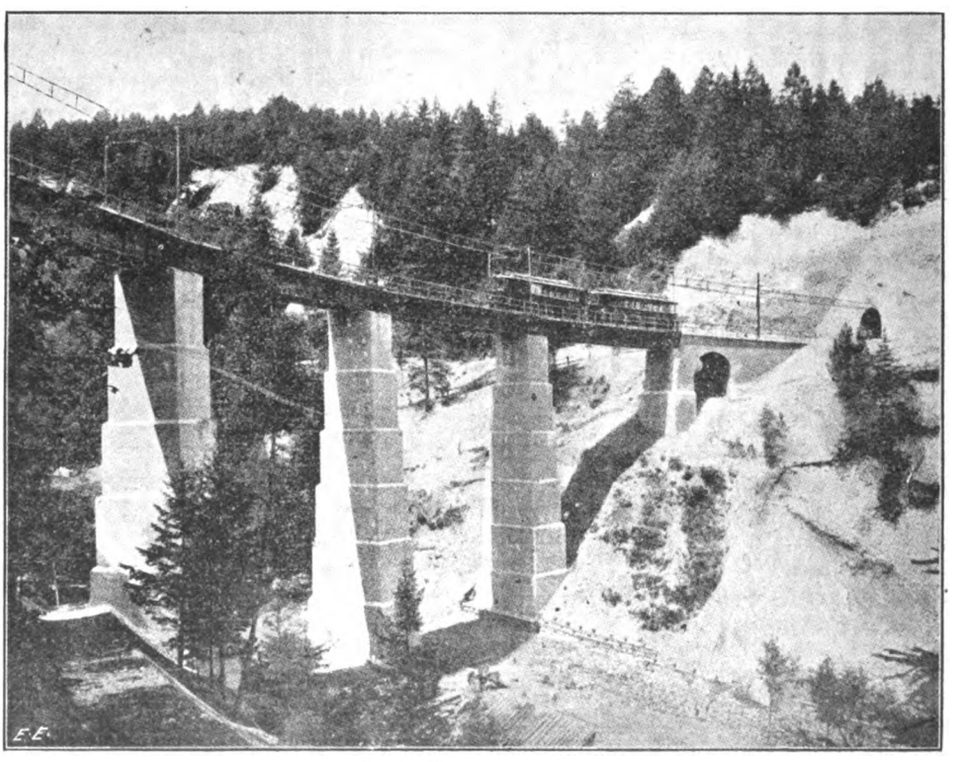

FIG. 4.—Viaduct at Mutters.

Technical Description.

The Stubai Valley Railway lies between Innsbrück, the capital of Tyrol, and Fulpmes, a small manufacturing town. It has a length of 11·4 miles, and taps five places *en route* (see the map, Fig. 2). The accompanying diagram (Fig. 3) shows the gradients over three different sections of the track. There is a rise of 280ft. over the first 6·75 miles, the next three miles being practically level track, while the last section falls about 217ft. to Fulpmes. The highest altitude reached lies at 3,300ft. above sea-level. The heaviest gradient is 4·6 per cent, and the curves have a minimum radius of 130ft. Two tunnels and a like number of viaducts occur. One of the latter is shown in Fig. 4. The gauge is 1m. (3·28ft.), and is on private ground. It is provided with rails of Vignoles section, weighing 36lb. per yard.

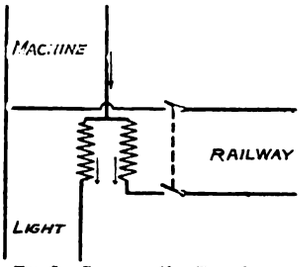

Fig. 5.—Compensating Transformer.

Provision is made for housing and overhauling the cars at Wilten, where repairs are also executed. The car-shed at Wilten has two rail tracks, and is 180ft. long. A further shed with accommodation for two cars is provided at Fulpmes. As has been mentioned in the foregoing, the railway is supplied with current from electricity works on the River Sill belonging to the Innsbrück Corporation. This current is conveyed overhead for a distance of about 1·9 miles at a voltage of 10,000 (see Fig. 2). The feeder cable consists of two wires, each having a sectional area of 50 square millimetres. Two-phase alternating current is generated, and provision is made for taking the supply from either phase. It is noteworthy that the traction current is furnished by the same machines which take the lighting load. On this account the conditions by which

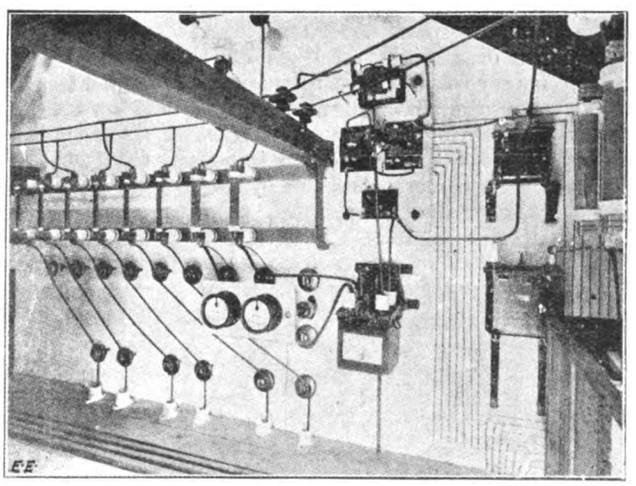

Fig. 6.—Interior of the Kreit Transformer Station.

the railway company are bound in regard to the fluctuations of their demand have been made very stringent, with the object of preventing unnecessary disturbances of the lighting supply. These disturbances are counteracted by means of a transformer, one winding of which is in series with the traction feeder cable and the other in series with the lighting supply (Fig. 5). A sudden demand from the railway thus boosts the lighting supply to compensate for the drop in the alternator. This compensation for the potential drop is most successful. The main 10,000-volt transmission line terminates at the Kreit distributing centre (Fig. 6). The primary current is conveyed from this centre by wires (two in each direction) of 25 square millimetres sectional area to the transformer stations. With the exception of a short length, the primary conductor is carried on the trolley masts. Porcelain insulators are used for its suspension. These are brown glazed, and, notwithstanding heavy snowfalls and unfavourable atmospheric conditions generally, have stood extremely well. During 14 months' working not a single failure occurred over the whole 10 miles of primary conductor due to failure of the porcelain insulators. At the distributing centre and feeding points the pressure is reduced to 2,500 volts. Two 75-kw. transformers (Fig. 7) are installed in each of the three transformer stations, a third unit being held in reserve. The three transformer stations are connected in parallel through the trolley wire and rails. Two of these stations suffice for the present needs of the service, the third having been erected in view of future developments. The transformers themselves are immersed in oil and require no attendance, the whole of the distributing system being supervised from the Kreit centre. The fuses at the different feeding points, which can be readily disconnected both from the 10,000 and the 2,500 volt sides, are so proportioned that they blow only on prolonged short-circuits. In the event of

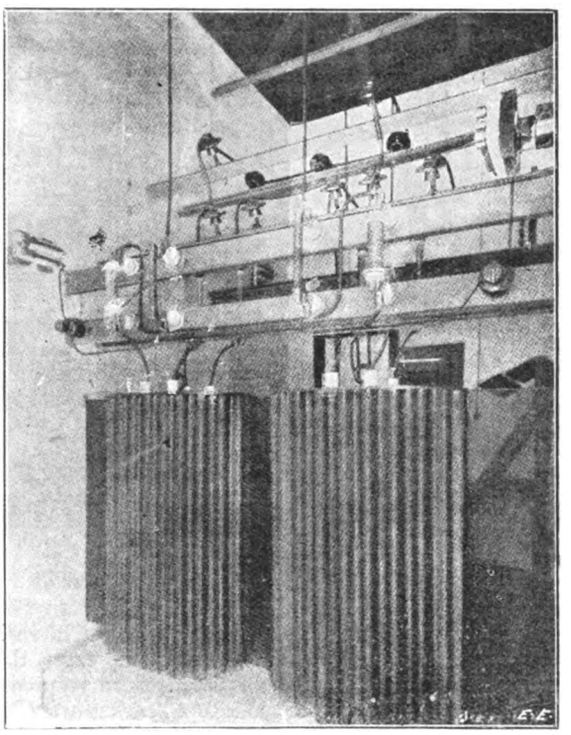

Fig. 7.—Two 75-kw. Units in Transformer Station.

line troubles, the automatic oil switches at the distributing centre are first to act. Hereupon the attention of the attendant is attracted by an alarum which is actuated by the automatic switches. According to the telephone message received, meanwhile the supply to the line may be wholly or partly restored. The necessary arrangements are so simple that one man suffices to look after the whole. Hence the supervision of the current supply to the line costs the company next to nothing. The connections are shown diagrammatically in Fig. 8.

The trolley line consists of a single hard-drawn copper wire of 53 square millimetres sectional area, fed with current at a mean pressure of 2,500 volts. This high working potential involves special precautions in order to secure mechanical reliability and ensure good insulation. Even when hard-drawn, copper is an inferior material so far as tensile strength is concerned, and having regard to the great differences of temperature experienced in the Stubai Valley, it would have been dangerous to have adopted the method of suspension commonly used for tramways. True, this meets requirements for low-tension systems, but, nevertheless, the inherent defect is there, that it subjects the trolley wire itself to a severe mechanical strain. The method of suspension adopted on the Stubai Valley Railway resembles that employed on the Spindlersfelde line, support being given to the trolley wire at intervals of 13ft. At these intervals it is suspended from a steel wire of 5mm. diameter by means of vertical wires.

Digitized by Google

Any desired amount of sag can be given to the steel wire, and in this case it is so adjusted to the unequal intervals between the trolley masts that with 20deg. C. of cold there is a maximum strain of 440lb. The longest clear span is 160ft., while the tensile strength of the steel wire is 155lb. per square millimetre, whence it follows that at the weakest spot there is still a factor of safety of 7, quite apart from the supplementary strength lent by the trolley wire (see Fig. 9). This supporting wire—always in the vertical plane above the trolley line—is attached to high-tension porcelain insulators by means of cast-iron caps, these insulators being cemented to bolts, which are secured in turn by means of clips to U-shaped iron bracket arms. In order to further improve the insulation of the supporting wire, globe strain insulators are inserted, one on either side of each point of suspension, at a distance of about 2·3ft. from same. Should one of the high-tension insulators break, the insulation is, therefore, still maintained. Porcelain insulation is used throughout, being superior to every other material both in regard to surface leakage and durability. Due to the careful design of the insulators, the arrangement adopted has also proved equal to all mechanical requirements.

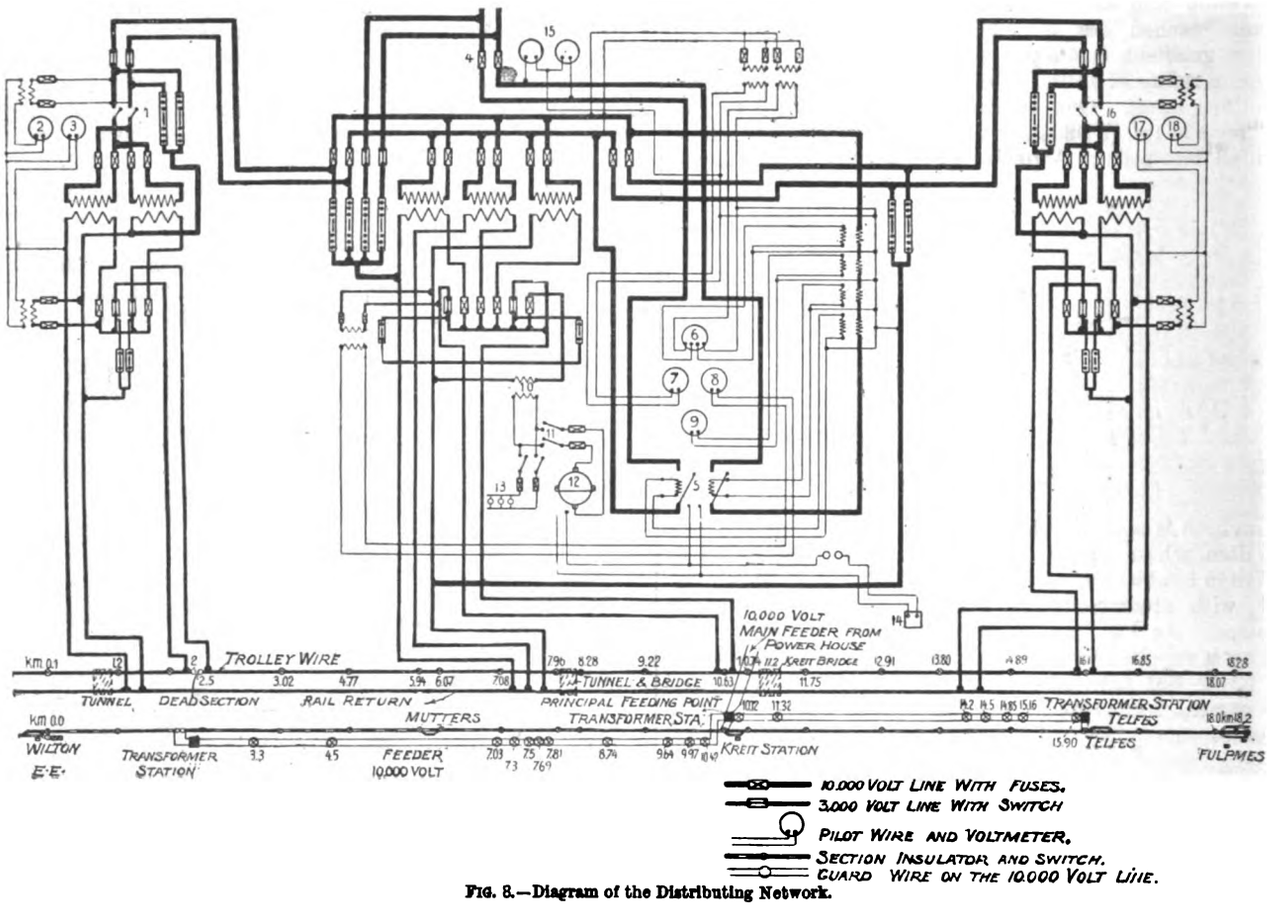

FIG. 8.—Diagram of the Distributing Network.

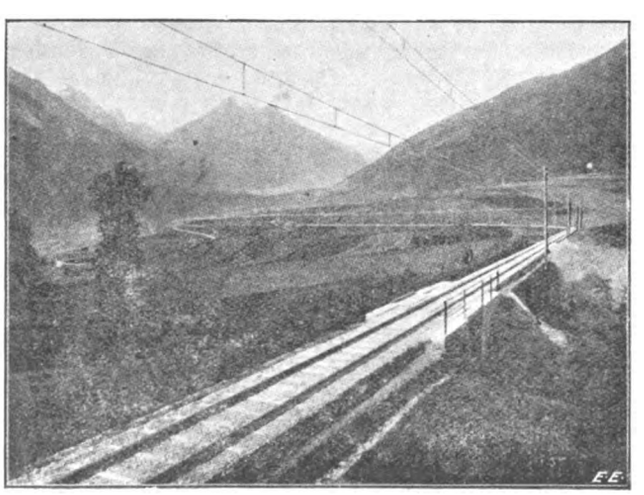

FIG. 9.—A Straight Run.

The vertical wires depending from the principal carrier are attached to the trolley wire by means of special terminals of extremely light and simple construction. Bow collectors are used on the motorcars, and the trolley wire forms a continuous conductor of ample elasticity in all directions, which, thanks to the method of suspension, presents no sharp obstructions to the passage of the bow over its contact surface, thus ensuring continuous sparkless collection even at the maximum permissible speed. At curves—indeed, the number of straight stretches on the Stubai Valley Railway is very small—the construction shown in Figs. 10 and 11 is adopted, similar insulators being used for the tie wires as for securing the principal carrier, as also at points and anchors. Span girder construction (Fig. 12) is employed where more than one track is laid, since the distance between the tracks is too small to admit of the erection of centre masts.

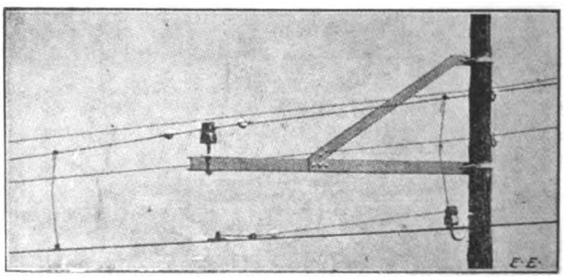

FIG. 10.—Arrangement of Tie-Wire on Curve.

It will be seen that rigid suspension has been rigorously avoided. An exception occurs in the case of two tunnels *en route*, in which the available headway did not admit of the same degree of elasticity being obtained (see Fig. 13). The individual points of suspension consist here of an ear and steel bolt cemented into a porcelain insulator, the latter being provided with an iron cap, which is screwed to a cross carrier. In the open the trolley wire is fixed at a height of 18ft. above the rail heads, and in the tunnels 13ft. Hence there is a difference in level amounting to 5ft, so that the bow collector lies almost in a horizontal position in the tunnels.

At intervals of five-eighths of a mile, at both sides of each

Digitized by Google

station, and at the approaches to the termini, section insulators and section switches are provided in the trolley line. The former each consists of four high-tension porcelain insulators fixed into an iron frame, double insulation being provided. The arrangement is such that contact between the bow and insulators is impossible. At the

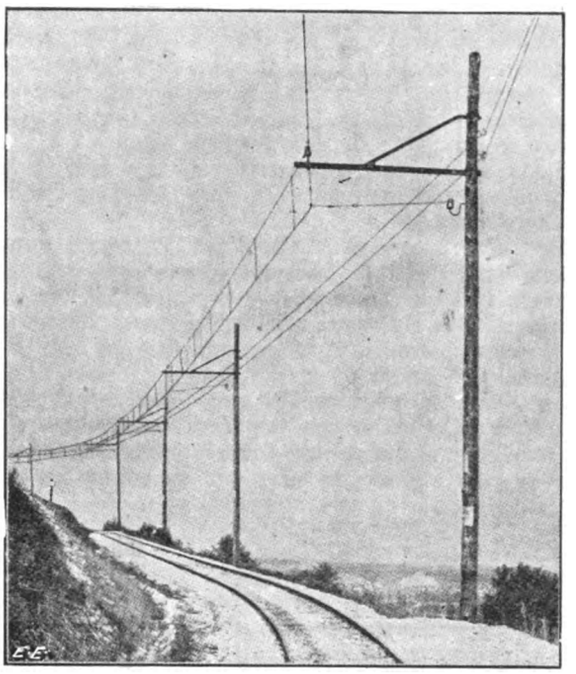

FIG. 11.—Overhead Construction on Curve.

same time provision is made at these points for taking up sag and anchoring the conductor.

Following are the approximate quantities of materials used: 9·5 tons of copper for the trolley line, 3·5 tons of steel wire, 28 tons of wrought-iron bracket arms, and 6 95 tons of copper for the feeders. The value of these materials is £2,000 in round figures. Had the polyphase system been adopted, an additional sum of

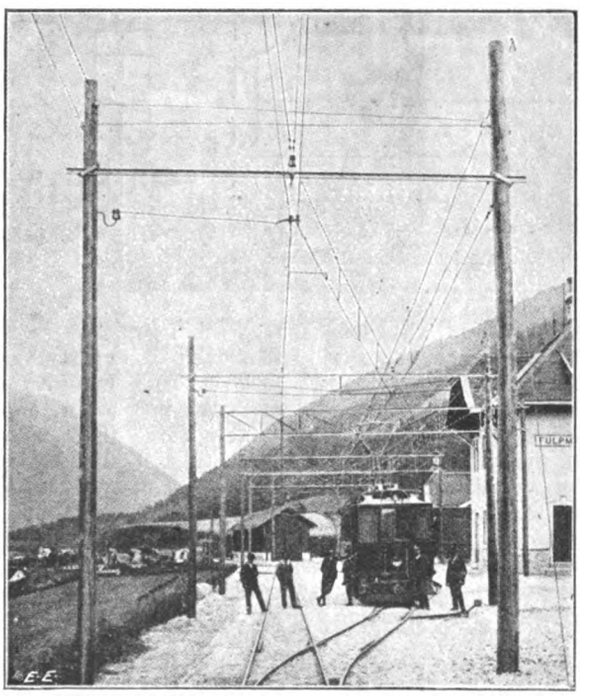

FIG. 12.—Span Construction over Double and Treble Tracks.

£760 would have been required for trolley wire alone. For the third-rail system 34 truck loads of steel, representing a value of roughly £3,200, would have been necessary. Hence there is undoubtedly a gain in favour of the high-tension system so far at least as the cost of the distribution work is concerned.

The track rails serve as a return conductor. They are polished at the joints, as likewise the fishplates, and coated with a metal paste which prevents oxidation of the contact surfaces. The removal of some of the fishplates after 14 months' wear showed that the surfaces thus treated were still thoroughly clean. The absence of copper rail bonds has proved very advantageous, since the maintenance

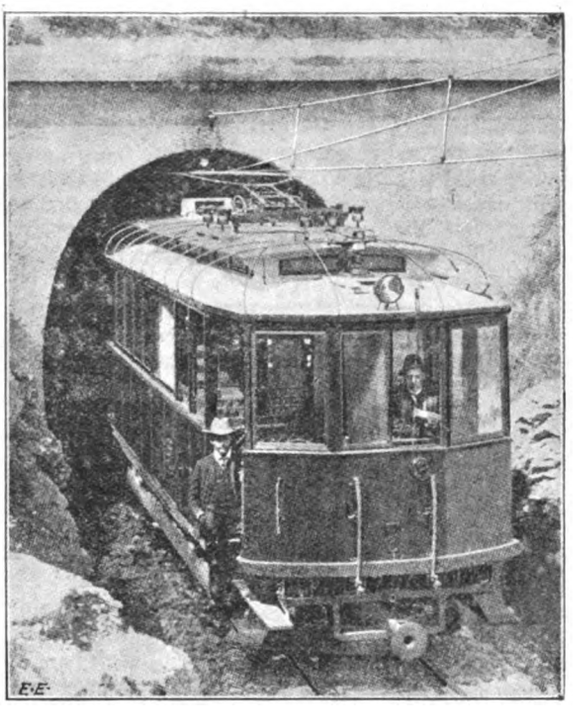

FIG. 13.—Overhead Construction at Tunnel Entrance.

of the rail return involves no special attention. The simple act of tightening up fishplate bolts which may have become slightly loose restores good electrical continuity—as long as the joints are tight the return is all right. But the impedance of the track per kilometre is nevertheless considerable, due to the light rails employed, the great distance between these rails and the trolley wire, and the high frequency (42 periods per second) of the current. In fact, numerous measurements, which coincide with the estimated figure, show it to be about 0·9 ohm.

(To be continued.)

TRAMWAY PRACTICE IN AMERICA.

London County Council Report.

The following is an abstract of an excellent report prepared by Mr. A. L. C. Fell, the chief officer of the London County Council tramways, on his visit to America in May last year. During his stay in America Mr. Fell visited New York, Washington, Pittsburg, Toronto, Niagara, Buffalo, Boston, Albany, and Schenectady, and inspected the various tramway undertakings. In the course of his inspection he found that the officials of the street railway companies and of the large manufacturing concerns placed every facility in his way for acquiring the valuable information presented in his report. The general impression gathered by Mr. Fell with regard to the tramway problem in the States was that American engineers and their financial supporters are much more inclined to take the view that where there is a main road out of a city, or a possibility of conecting two cities, there should be a street railway to develop the district. In many instances the undertakings do not prove a financial success for some years, but the country is being developed so rapidly that the risk is only a small one when the ultimate results are taken into consideration. The greatest incentive to the rapid development of street railways is the fact that on the interurban lines the speed is in the majority of cases unlimited, and in several instances he travelled at a speed of 50 miles an hour on tracks laid at one side of the road with perfect safety, so that with the cheap fares, high speeds, and rapid acceleration possible with electric traction, people with very moderate means are able to live a con-

Digitized by Google

siderable distance from the centres of the cities where they work. In most of the smaller cities the trackwork is of the cheapest possible character, and apparently this is all that is required until the undertaking is in a position to instal the work in a more permanent manner. It does not, however, follow that the track in important cities is satisfactorily maintained. The condition of the paving in some of the cities which he visited is disgraceful, and would not be tolerated in this country. This point should be taken into consideration when comparing the operating costs with those of similar undertakings in London.

In view of the fact that the London system is the conduit one, special attention is paid by the author to the work in New York and Washington carried out by this system. The details of the Washington conduit are shown

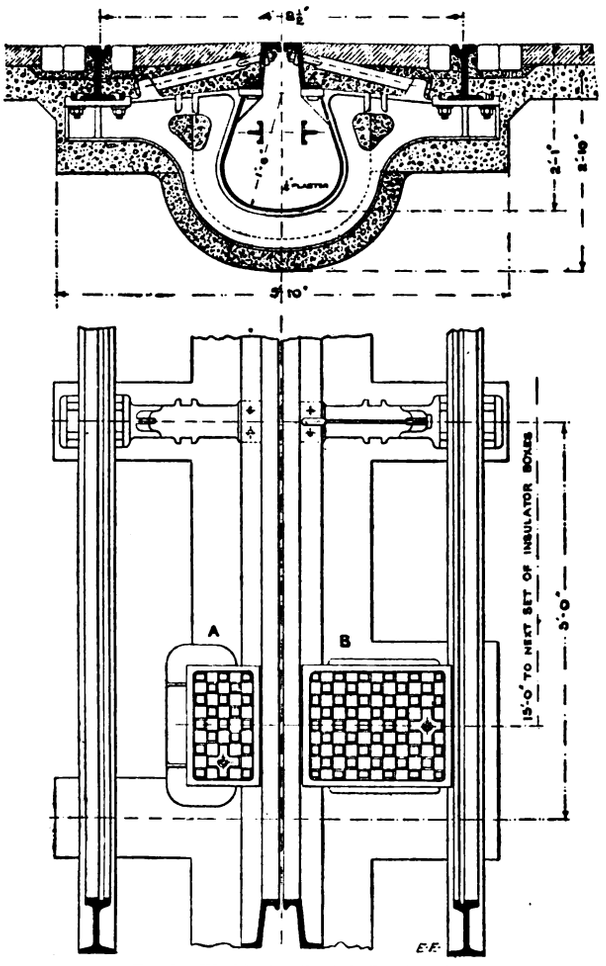

FIG. 1.—Washington Conduit Construction.

in Fig. 1. There are two companies operating in Washington, one using the trolley and the other the conduit system. The changing over from one system to the other is carried out in a pit under the track, where a man is employed to remove and replace the ploughs, the conductors on the cars attending to the trolleys. The time taken in changing from one system to the other is very short, but the pit is a dangerous obstruction in the roadway; it is covered by a folding iron trap-door, but this is left open when the man is in the pit. In a very busy thoroughfare it would be necessary to keep men constantly in the pits, and special arrangements would have to be made so that the trap-door over a pit would not be open unless covered by a car. The opinion is expressed that this arrangement is not so advantageous as the plough-lifting device used at Streatham. One very special feature in connection with the construction of the conduit lines in Washington is that a large manhole is placed every 31½ft. along the track, and the mud or dirt in the conduit is collected by an insulated hand scraper made to fit the bottom of the conduit. It is then removed with hoes or scoops through these manholes without difficulty. In London the sump pits and manholes are 40 yards apart, so that if there is an accumulation of mud or dirt in the bottom of the conduit it is practically impossible to push this along at one operation to the nearest sump pit, as the dirt builds up in the conduit and is liable to short-circuit the conductor tees, and trouble is caused by mud being splashed up on the insulators. In Washington the mud and refuse have to be pushed such a short distance that no trouble is experienced. No water is used in Washington for cleaning when the dirt in the conduit is comparatively dry, but the difference in the working conditions is emphasised by the fact that the conduit is only cleaned out about once in six months, whereas in London this has to be cleaned every few days. The method of arranging the intermediate manholes is shown on Fig. 1, at B Mr. Fell advises that the cost of cleaning in London could be reduced if more frequent manholes were provided.

The trolley tramways in New York, Pittsburg, Toronto, Buffalo, Boston, and the through system between Albany, Schenectady, and Troy, were viewed by Mr. Fell, and are described in his report with well prepared illustrations. We are most interested at the present time with Mr. Fell's conclusions on points of detail than on descriptions of systems. For instance, on the great question of conduit ploughs, those in use on the New York street railways are of a much lighter design than those in use on the Council's tramways, but a great deal more care has been taken in the

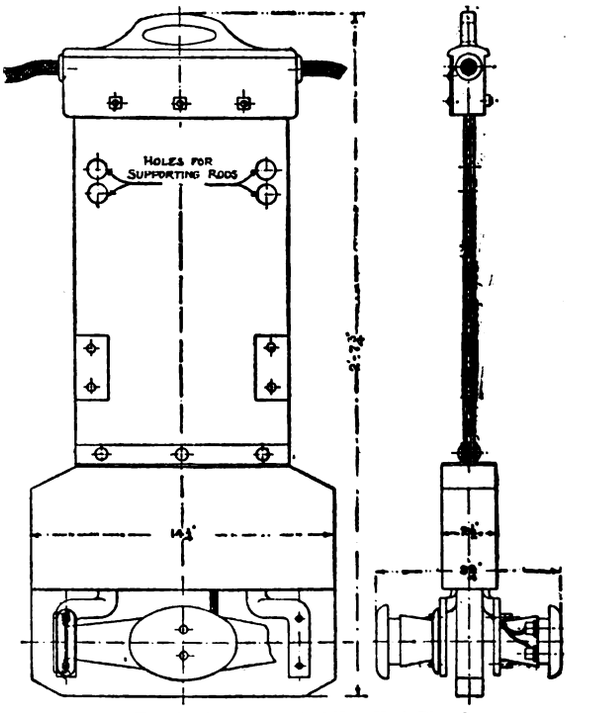

FIG. 2.—Arrangement of New York Plough.

construction of the ploughs in Washington than in New York, and apparently much less trouble is experienced in the former city. It must, however, be taken into consideration that the climatic conditions in Washington are much more favourable than in New York. Figs. 2 and 3 give particulars of these ploughs. Fig. 4 illustrates the latest type of plough on the Council's tramways. In New York the type of plough in operation is very cheap, and the question of repairs is reduced to a minimum. If any defect develops in the wooden base of the plough, it is simply scrapped, and apparently, from the size of the scrap heap, troubles in this direction are not infrequent. Apart from the base troubles, the blade of the plough frequently becomes twisted when passing through special work. Mr. Fell thinks this is chiefly due to the fact that the ploughs are mounted on two parallel round rods, which run through holes drilled in the plough blade. There is very little clearance in these holes, so that unless the plough is at right angles to the supporting rods it will not travel freely sideways, and if by accident the plough takes the wrong road at a junction it becomes jambed. With the ploughs in use in Washington and on the Council's tramways this is not possible, as the ploughs are free to drop out of the supporting frame. In Washington, as all the conduits are laid in the centre of the tracks, it is only necessary to have

Digitized by Google

a supporting guide about 12in. long. In London, however, the supporting guides have to run the full width of the truck, as the conduit in the interlacing line at Greenwich, and also in all the car-sheds, is run close to one of the track rails. The ploughs on both the systems in Washington are substantially built, and every endeavour has been made to keep the moisture out of the base. The chief fault, however, is that the bases are made of wood, as was the case with the ploughs originally supplied for the Council's tramways, but as there is practically no mud in Washington, very little trouble is experienced with these ploughs burning out, and it is not found necessary to dip the wooden base in any compound, such as was required in London with the wooden ploughs, and which has to be extensively used on the ploughs in Paris. The Washington ploughs in their present state would not run more than a few days in wet weather in London. The engineers in both New York and Washington admit that there is room for improvement in their ploughs. Mr. Fell thinks that it would reduce their cost of upkeep appreciably if they adopted the Council's hard base rubber plough, which gives most satisfactory results in all weathers. After a careful examination of the ploughs obtained during his visit, Mr. Fell is of opinion that it would be false economy to sub-

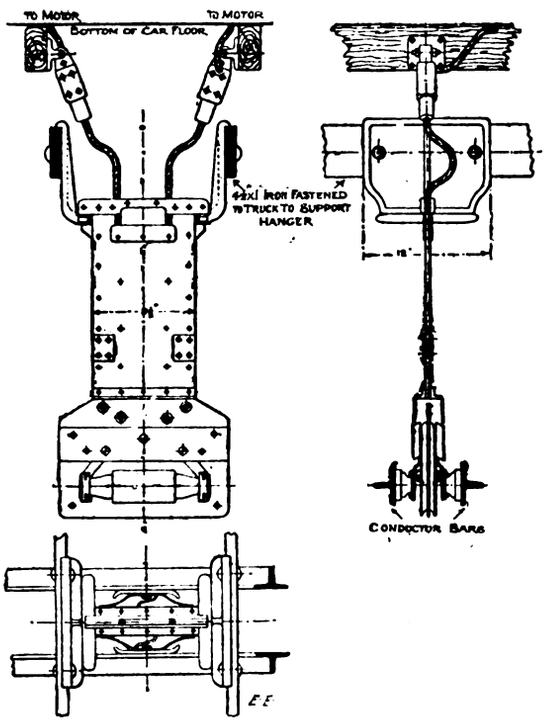

FIG. 3.—Arrangement of Washington Plough.

stitute a cheaper form of plough for that now in use in London, as so much depends on the proper working of the plough. A cheap plough will not only be an expensive item with regard to upkeep, but it may cause serious delays in the traffic, and heavy loss would be entailed.

As regards motors, there is in America a tendency to increase the horse-power and to employ motors ranging from 40 h.p. up to 75 h.p. each. The result is more rapid acceleration, and the resistance and controlling devices are so well arranged that full speed is attained in a very short distance without unduly jerking the car when starting. Many new features have been recently introduced into the design of the tramway motors which Mr. Fell is introducing into the specification for new cars now to be issued for the London system. Steel wheels are rapidly superseding chilled iron wheels in the States, due evidently not only to greater safety at high speeds, but to fewer flats being developed, which enables the car to keep in service for a much longer time before the wheels are taken out to be cleaned. At Buffalo steel wheels have been found to run on an average 35,000 miles before needing to be turned up.

As regards brakes, Mr. Fell found that on the majority of the lines inspected air brakes are in use. Electromagnetic track brakes have been largely superseded by air brakes, as it was found that the additional strains thrown on the motors greatly increased the cost of upkeep and decreased their life. He adds that the most recent types of electric magnetic brakes used in this country have not yet been tested in the States. In Toronto he noticed a type of brake called the momentum brake, which is made of steel and malleable iron, and weighs about 260lb. It comprises a friction disc formed on a sleeve which is keyed to the car axle, a second friction disc sliding longitudinally, with a feather key on the sleeve, in a flanged drum journaled on the sleeve between the friction discs. On this drum is wound a chain which is connected with the brake levers. On the sides of the drum annular friction surfaces of compressed wood fibre are fixed which engage the two steel discs. There are suitable mudguards attached to the drum flanges for the purpose of keeping grit from the friction surfaces. On the end of the sleeve is screwed an adjustable bevel-sided nut, and the hub of the movable disc is similarly bevelled, which forms a V-shaped groove with which the taper wedge wheels may be engaged to force the friction discs and drum into contact. The wedge wheels are supported from a suspension bar which is fastened to the car truck. There is also a connecting rod from the live wedge wheel lever to the brake mast, so that by turning the brake mast a quarter of a turn it will engage the wedge wheels with the nut and movable disc, and force the latter against the drum, which will be thus engaged between the friction discs and caused to rotate, thereby winding up the brake chain and applying

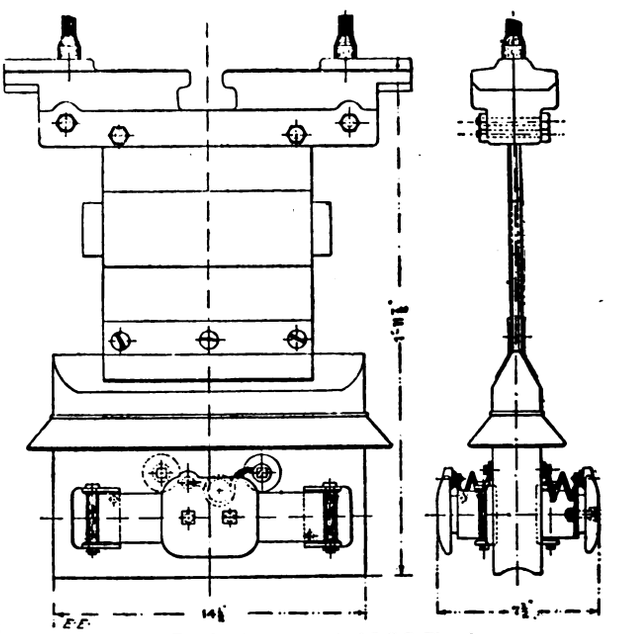

FIG. 4.—Arrangement of L.C.C. Plough.

the shoes to the wheels in the usual manner. To release the brake, the motorman simply places the brake mast handle back to the position in which it was in before application. This type is to be tried on a car in London.

As regards permanent way, extended yokes are used both in Washington and New York, as are shown in Fig. 1. These facilitate the replacement of rails when they have to be renewed. On the vexed question of junctions between tramway rails and paving, they seem to be not so far in the States as we are in this country. Certain cases are mentioned where the whole of the line work is in a very bad condition. Fig. 5 shows a section of the rail used in New York. Electric welding has proved very successful in Buffalo, where 32 joints have been made on the Lorain system. They have been in use since 1899 with only 1 per cent. of breakages. In Cleveland joints are now welded by the Thermit process. The question of rail corrugation is one that requires very serious consideration both in this country and in America, and unless the trouble is promptly dealt with serious damage will be done to the equipments and trucks, and the rails will have to be renewed before they are worn out. In this country corrugation has appeared on the rails of nearly every electric tramway system, the corrugations varying in length from 2½in. to 5in., the worst corrugations appearing at curves where

Digitized by Google

a short wave is formed on the outer rail and a long wave on the inner rail. The corrugation at first appears on the outer rail. Corrugation gave great trouble shortly after the cable tramways started running on the Brixton section,

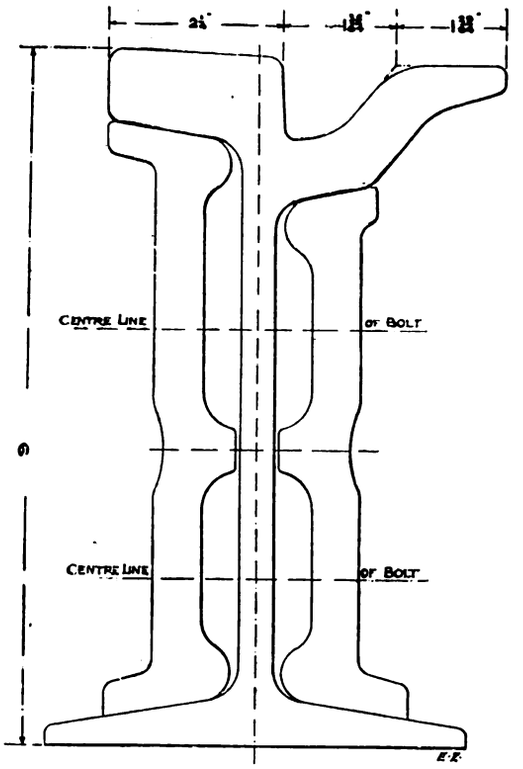

FIG. 5.—Section of Rail, New York.

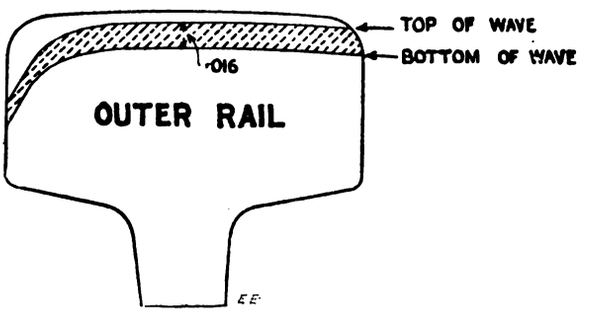
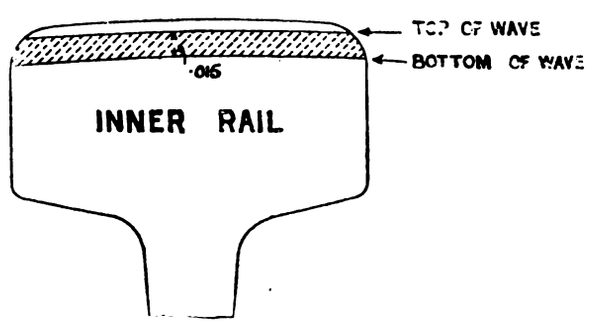
but in this case it was found that the corrugation at the curves started on the inner rail, and was transmitted to the outer rail, and the long corrugation was on the outer rail, and not on the inner rail. No corrugation has been noticed on the rails used for horse traction, but it has



Sketch showing depth of wave or corrugation on the outer rail of Rollins Street curve, south bound. Radius 1,000ft., super-elevation 4in., gauge 4ft. 8¼in. Speed of trains about 25 miles per hour. Average length of wave 2ft. 7½in. Length of service 365 days.



Sketch showing depth of wave or corrugation on the inner rail of Rollins Street curve, south bound. Radius 1,000ft., super-elevation 4in., gauge 4ft. 8¼in. Speed of trains about 25 miles per hour. Average length of wave 2ft. 6 7/8 in. Length of service 365 days.

FIG. 6.

appeared on steam-driven tramways, but never on steam railways. In every city visited in America, except Buffalo, corrugation was to be found in a more or less marked degree. Apparently the higher the speed the greater the length of the corrugation wave. On several of the inter-urban lines the cars are run at speeds of from 20 to 30 miles per hour, and the corrugation in some instances was as much as 8in. long. On the Boston elevated railway, where the cars are run at upwards of 40 miles per hour, the corrugation was no less than 31in. long. Fig. 6 gives the actual dimensions of one of the corrugations inspected. The trouble on this line is so serious that the rails have to be renewed every few months.

Before going to America Mr. Fell had for a considerable time been engaged in investigating this matter, and formed the theory that the trouble was originally caused by unevenness on the rail surface setting up a slight jumping or bounding action in the car wheels. He considers that the unevenness might be due to three causes: (1) chattering or vibration of the rollers when commencing to roll the ingot into a rail, causing a rough rail surface: (2) uneven or wide joints between rail ends rigidly supported on a concrete bed; (3) jumping action set up in car wheels by variations on the wheel or track gauge. To ascertain if his first theory was correct, he made some tests in the New Cross car-shed before the rails had been used in any way by the cars. A long emery block, fitted under a truck, was run lightly over several lengths of track, and a distinct corrugation was noticeable on the rail surface, although in some instances it was not very regular in form. About nine months ago he had a water tank car fitted up with a grinding apparatus, consisting of a carborundum block, 10in. long by 2½in. wide, which could be pressed down on to the running rails. By this means some of the worst corrugations were ground out, and have not yet reappeared. The corrugation of the rails is becoming somewhat serious on all the sections, but additional grinding apparatus is being fitted on the new water tank cars which will shortly be delivered, and he hopes to be able to grind out the waves. No attempt has been made hitherto in America to get rid of the trouble in the manner now suggested. With new rails arrangements should be made, if possible, for passing them through a grinding machine after rolling; the corrugations are so slight that very little would have to be done to prevent the trouble developing in a serious manner at a later date.

There then follows a large section of the report devoted to the use of steam-turbines in generating stations providing energy for tramways. This subject has been so frequently dealt with in our columns that we do not propose to give more than Mr. Fell's advice that turbines should be used when completing the second half of the Greenwich generating station. This would contain 5,000-kw. turbines instead of four 3 500 kw. reciprocating engines. The single-phase system of traction is also dealt with in the report, and some figures given which were obtained by the General Electric Company on the Ballston line. These figures (reproduced herewith) give a comparison between the direct-current and alternating-current single-phase system over the same length of track.

—	Direct-current line.		Alternating-current single-phase line.
Length of run	1·6 miles	...	1·6 miles
Weight of car	31·55 tons	...	31·55 tons
Time	180 seconds	...	180 seconds
Average current power	229 amperes	...	346 amperes
Average voltage	606	...	425
Kilovolt-amperes full speed on level	98	...	110
Volt-ampere-hours per ton-mile of given run	86·3	...	125·5
Average speed	32 m.p.h.	...	32 m.p.h.
Schedule speed, including 15 sec. stops	29 5	...	29·5

The car operated on this line is equipped with compensated motors and weighs 30·4 tons total without passengers, and is geared for a maximum speed of about 43 miles per hour on the level. The car has a 32ft. body, is 43ft. over all, and has a seating capacity of 44 passengers. The body is mounted upon trucks having 6ft. wheel base, each truck carrying two compensated motors, each motor equivalent to a 75-h.p. direct-current motor, standard railway rating.

In conclusion, Mr. Fell states: "In the foregoing report I have only briefly dealt with a few of the innumerable matters of interest brought to my notice during my short stay in America, but the information which I gained will, I feel certain, be of the greatest service when considering the future developments of the London tramways. I cannot close this report without acknowledging the valuable aid

Digitized by Google

which I received from the general managers and engineers of the systems which I inspected in the various cities, and the officials of the General Electric Company and the Westinghouse Company."

OUTER DARKNESS, OR WHAT MIGHT HAVE BEEN.

BY THE WORM.

I was out of a job. I often am. Now I don't mind being out of work, as a rule, but I found running light was so very inefficient that I decided to go on load again. So I decided to look round for what is euphemistically known as a "situation." I prefer to call it "a fix," so I searched the "Fixes Vacant" columns; but though I have hitherto been able to get into a fix fast enough, yet in this case I wasn't in it, so to speak. At last I struck the following:

TAFFYSHIRE COUNTY ASYLUM.—Wanted, at once at the above asylum, an assistant engineer (mechanical and electrical experience essential). Applicants with institution experience and a knowledge of music preferred. Wages, 30s. per week.

"That's me!" said I. "Institution experience and a knowledge of music. I attended all the meetings of the I.E.E. for two years. There's the institution experience, and I'll play them anything they like on a piano, from "Bill Bailey" to Chopin's "Funeral March" in five flats, which ought to suit 'em. It's as good as got."

So, being close to the asylum, I decided to apply personally. I didn't like the look of the front door—it had a gaoly look—so I hunted round and found a small side door, at which I knocked. It was opened with amazing suddenness by a very short, fat man. He was dressed in grey and wore knickerbockers. He was just a broad smile embodied. His "fair round belly" (quotation), his dimpling, clean-shaven face, his sleek, curved hair, all seemed to smile; and when he moved, his plump calves simply shook with laughter.

"Good morning!" he said, with pleasant dignity. "In what way may I serve you?"

"I've called about the assistant engineer's appointment. 'Knowledge of music and institution experience preferred,' you know."

"Ah, yes. I've been expecting you." And he led the way into a large drawing-room, at one end of which was a grand piano.

"Pray be seated. You will understand that executive musical ability is of great importance in an organisation of this kind. The soothing and refreshing effect of sweet music on an overworked brain cannot be too strongly emphasised. Kindly oblige me by playing a selection—something in the lighter vein"—and opening the piano, he waved me to the stool. I sat down and plunged into that popular cake-walk, "Down South." I heard behind me a series of bumps, and, on turning my head, discovered him capering around with amazing agility. He hopped and skipped and jumped and pirouetted, advanced and retired, set to partners with himself, and always came in on the beat with a vigorous nod of his head. This finished, he smilingly resumed his dignity as I would put on my hat, and proceeded, "In a matter of this kind it is essential that I should know something of your social position. What class of society do you move in?"

I was about to reply when a tall, pale lady dressed in white drifted in. She was carrying some pieces of celery and the top of a cauliflower. He bent gracefully over her extended hand, and made inquiries about her health. Then turning to me he said, "Allow me to present the mayoress, my wife. I'm the mayor, of course" ("And corporation,' I said to myself, admiring his rotundity) I bowed, and murmured my felicity with one eye on the door.

"My dear," she said to him, "how often must I tell you I'm not your wife and not the mayoress." Turning to me she continued, smiling, "I'm Ophelia and he's Hamlet."

"I'm not Hamlet," he said, looking red and angry.

"Oh, how can you say so? Why, I saw you this morning with your stockings down." And, ignoring his snort of indignation, she turned to me and handed me a piece of celery.

"There's rosemary for remembrance." I bowed again, this time with both eyes on the door. "Now play me something weird, and I'll go mad for you."

"But, madam," I expostulated, "why should you?"

"Why shouldn't I?" she replied, surprised.

Just then a man in uniform came in, and, finding what I had come for, he conducted me to an office, leaving my two friends arguing as to who was who. The next man I interviewed was not nearly so pleasant. He had a cold, fishy eye, and was sarcastic. He inquired my business. I stated my qualifications, adding that I reckoned my own demagnetising smile would bring down the voltage of any high-pressure lunatic he liked to trot out. He received my remarks with obvious incredulity, requested me to send in my application by letter, and advised me to avoid the neighbourhood of lunatic asylums in future, unless I wanted to commit mental suicide. I came out by the front door, directed by the man in uniform. I'm still out of a job. But I've got my rosemary, and I remember.

FORTHCOMING EVENTS.

SATURDAY, DEC. 30.

Robertson Social Club.—At 7.30 p.m., dance.

Royal Institution of Great Britain.—At 3 p.m., "Astronomy," by Prof. H. H. Turner.

TUESDAY, JAN. 2.

Royal Institution of Great Britain.—At 3 p.m., "Astronomy," by Prof. H. H. Turner.

THURSDAY, JAN. 4.

Royal Institution of Great Britain.—At 3 p.m., "Astronomy," by Prof. H. H. Turner.

Rontgen Society.—At 8.15 p.m., "The Present Position of Radio-Activity," by Prof. F. Soddy, M.A. (presidential address).

SATURDAY, JAN. 6.

Royal Institution of Great Britain.—At 3 p.m., "Astronomy," by Prof. H. H. Turner.

Institution of Electrical Engineers (Manchester Local Section).—Students' visit to Chloride Electric Storage Co.'s works.

Institution of Civil Engineers.—Jan. 9, at 8 p.m., papers.

Royal Institution of Great Britain.—Jan. 9, at 3 p.m., "Astronomy," by Prof. H. H. Turner.

Association of Engineers-in-Charge.—Jan. 10, at 8 p.m., "Storage Batteries," by Mr. F. Crewster.

Liverpool Engineering Society.—Jan. 10, at 8 p.m., "Some Economic Aspects of Electric Power Supply," by Mr. H. W. Wilson.

Institution of Electrical Engineers (Manchester Local Section—Students' Section).—Jan. 12 at 7.30 p.m., "The Electrical Equipment of Automobiles," by Mr. J. C. Ward.

Institution of Civil Engineers.—Jan. 12, at 8 p.m., students' meeting "The Theory of Machines," by Prof. J. D. Cormack.

APPOINTMENTS VACANT.

Draughtsman. Apply to G A 5, *Electrical Engineer* Office. See advertisement.

Premium Pupil, City Electrical Engineer, Carlisle. See advertisement in last issue.

Junior Technical Assistant, Northampton Institute. Applications by Jan 8. See advertisement.

Draughtsman, Manchester electrical engineering works. Apply, Box 519, General Post Office, Manchester. See advertisement.

Sales and Assistant Manager, electrical manufacturing and contracting company. Applications to 5,722, *The Electrical Review*, 4, Ludgate-hill, London, E.C. See advertisement in last issue.

Mechanical Engineer (with electrical experience), Southend Corporation Electricity Works. Commencing weekly salary of £2. 10s., rising by annual increments of 5s. per week to a maximum of £3.

Station Superintendent and Mains Superintendent, Calcutta Electric Supply Corporation. Salary for each appointment, Rs.450, Rs.500, and Rs.550 per mensem for each year respectively. Applications by noon on Jan. 3 to Calcutta Electric Supply Corporation, Salisbury House, London-wall, London, E.C. See advertisement.

Lecture.—On Monday Councillor J. A. Turnbull delivered an address on "Borough Electrical Undertakings," under the auspices of the Amalgamated Society of Engineers (Woolwich 4th Branch), at the Engineers' Institute, Glyndon-road.

TO ALL OUR READERS—

A Happy, Healthy, and Prosperous Year.

NATURAL v. ARTIFICIAL.

Another year in the history of the electrical era has ended, and the era may be said to have reached its twenty-fifth birthday, if we place the date of its birth in the year 1880. Two years previously—that is, in 1878—the International Exhibition of Paris turned attention to the possibilities of electricity, and in 1880, as was shown at the exhibition, also at Paris in 1881, one of the most important problems had been solved. The perfecting and the extension of electrical engineering has gone on with giant strides from then till now. Twenty-five years—a quarter of a century—and yet some of those who were in the forefront of the battle have gone to their rest, have joined that silent band, and passed to the bourne from whence no traveller returns. The history of almost every great departure is hid in obscurity. Those who have taken a practical hand in the earlier stages seldom or never leave a connected narrative of their actual labours; hence the historian has from disconnected data to make as good a guess at actualities as he can. Some, as we say, have gone, but others, and probably the more important workers, are still among us. Might we venture to urge them in some shape or other to compile and make public the exact steps due to them in the inauguration of a new and seemingly almost boundless industry. If we remember aright, it was Froude in one of his essays who discussed the probability of the truth of any one of the stories of history, and who pointed out the great difficulty of getting at the real truth of any one incident that happened in the street at any particular time of a day. Ten people who saw the incident would tell ten different accounts, each with different details. Is there a single departure that has been made in electrical engineering that is credited to the right man or men? We know of but one in which we could truthfully say to that man, and that man alone, was this new departure due—and this in the twentieth century, when reading, writing, and printing are as common as stones on the road. We do not wish to rake up old troubles, but are there two men living who can with any degree of accuracy tell us the exact position of Edison and Swan in the realm of incandescent lighting? That is but one of a score of questions, each more obscure than the other, where the aim is exact truth. Some years ago we tried to ascertain certain phases in the evolution of cable work, but no one seemed to know anything about the matter. References were to be found in the literature of the forties, but the few of these early workers living in the nineties had forgotten or never knew the exact truth about the incident to which reference was made. Ought we not at this stage of the world's history to be able to state with certainty the "who" and the "what"?

Has the ordinary man ever considered that each successive advance in civilisation brings with it new dangers, in that the advance is usually contrary to Nature's requirements. Sanitary engineers are continually fighting the insanitary conditions arising from concentrated population. The doctors have for years been preaching the dangers of the modern strenuous life. The manual worker has decreased his hours of labour and, if we may venture to say so, his daily and annual output. The strenuous life does not appeal to him, except he happens to be on piecework. It is upon the heads of departments and the principals of the undertaking that the trouble falls, and with them mental

Digitized by Google

and nervous diseases are increasing. Every fad and fashion seems to give rise to a special physical trouble. Not for the first time, but very forcibly, a writer in the *Times* of Dec. 26 directs attention to the "telephone in business." With the exception of the last paragraph of his letter we have no fault to find, but to that we give an absolute and emphatic denial. While objecting to that paragraph we must also protest against the position the *Times* takes in matters telephonic. Its articles hardly appear to be unbiassed, and seem to be from interested sources. Our appreciation of the great merits of the *Times*, of its unique position, of its evident desire to put the truth to its readers, renders it necessary that we should speak thus strongly. Dealing with this matter first, our information is from scientific men well versed in all electrical matters yet not engaged directly in telephonic enterprise, and these do not corroborate in the slightest the dictum of the *Times* correspondent or the *Times* leading article, which seems to adopt its correspondent's words, that the "British system . . . is . . . immeasurably inferior to that of all American cities."

We do agree with the view that a business man may be "completely broken down from strain and worry" because of the "constant strain of the telephone," and we do agree with the view in the *Times* leader, "that the evils . . . may be largely mitigated, if not entirely overcome, by a combination of efficiency with good sense and good manners." The introduction of the telephone meant for many men an attempt to add to their mental and nervous work more than their system could bear. They did not and many will not realise that flesh and nerves are incapable of unlimited use, or, indeed, of too much overstrain in a given amount of time; hence, if they persist in saying yea, nature steps in and says nay. One great want of the early years of the twentieth century is the realisation that physical powers are limited, and that the introduction of devices that require the physical energy to be used up at an accelerating rate must be met, in order to enjoy physical robustness, by a determination not to constantly attempt to carry an overload.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."*

THE COST OF POWER.

SIR,—I wish to call your attention to some figures which appear in the last number (Nov. 25) of *Science Abstracts* in the electrical engineering section. Abstract 1,575 gives a report on a paper read before an American electrical association by C. H. Hile. In a table apparently drawn up by the abstractor the cost of power in kilowatt-hours on the Boston Elevated Railway is given amongst other figures. The abstractor gives the average cost as 0·00778 cents = 0·00389d. per kilowatt-hour. To the minds of Englishmen all American figures are more or less open to suspicion, and none more than this. I strongly suspect that the word "cents," which is repeated, should be replaced by "dollars," giving the cost as ·778 cents = ·389d. As I believe the railway is direct current, the above cost is even then very low, and I can think of no other reason for these remarkable figures.—Yours, etc.,

ERNEST P. HOLLIS.

RE ANSWER TO QUESTION No 820.

SIR,—I thank Mr. E R. Alexander for his reply to my letter, in which he explains his argument very clearly.

I have to admit that he is perfectly correct in his argument, but it only holds within infinitesimal limits. It is quite true that two motors taking the same current at same voltage may give the same brake horse-power with their power factors differing from one another by quite an infinitesimal amount. The difference in such a case will be counterbalanced by the difference in all-round efficiency which will be caused by differences of iron and friction losses.

But the current varies inversely as the power factor, and, therefore, the ohmic losses vary inversely as the square of the power factor. As soon as the power factors differ by an appreciable amount, the ohmic losses in the motor with the lower power factor will quickly overwhelm the slight advantage of efficiency in the matter of iron and friction losses.

I would further say that it is decidedly in the consumer's interest to have a high power factor, as this means a smaller machine for a given output with given pressure and current. If a man wants a certain power, he must pay for the current required for that power and for the current used up in the ohmic losses. And this latter current varies *inversely* as the *square* of the power factor of the motor.—Yours, etc.,

P. WEIL.

THE PRODUCTION OF A DISINFECTANT (HYPOCHLORITE OF SODIUM) BY ELECTROLYSIS.

In an article on the above subject by Mr. C. V. Biggs, which appeared in our issue of Dec. 22, the author referred to the report for Maidenhead, made by Prof. Robinson, as having been made by Dr. Robinson. Of course, most of our readers will be aware that these experiments have been made by Prof. Henry Robinson, of Parliament Mansions, Victoria-street, Westminster, S.W., but as many of them are interested in the question of sterilising of fluids, we hasten to point out this small inaccuracy in order to save inquirers time and trouble.

MUNICIPAL ELECTRICAL WORK AT TURIN.*

As had been foreseen, the general vote in Turin has been given in favour of the municipalisation of the electrical works. The committee appointed to promote the matter presented a most favourable and promising report accompanied with flattering rhetoric on the future of the city, the support of the poor, and the necessity of waging war against greedy speculators. The same proposal advanced in its true aspect with correct proportions probably would not have found an equal consensus of approval; we are, therefore, proposing to look into it. We do not know how the matter may finish, as the technical advisers of the municipality are beginning to shift their responsibility, and some of those who voted in favour of the principle involved reserve the right of voting on either side in regard to financial points or on unforeseen details which they may consider it necessary to criticise.

The history of this undertaking commences with the purchase by the municipality for a figure above £13,000 of a good fall of water, the utilisation of which had been sanctioned by the Government. The waterfall is located at Chiomonte, in the valley of the Dora Riparia; its effective height is 1,050ft., and the volume of water about 880 gallons per second, so that something like 17,000 h.p is theoretically available. Against this fact the opponents to the project state that they have made independent measurements of the water during the driest times, and have found that a quantity of only 585 gallons per second was passing.

The definite scheme for the canal has been worked out by Engineer E. Perini, and the line for it was established after careful consideration of the nature of the ground to be traversed; it is partly in open cutting and partly in tunnel. The material of the locality will be used throughout in its construction. The greatest care in the design has been given to the intake to avoid damage from heavy rocks and stones being washed into it at the time of the torrent caused by the rapid melting of the snow on the adjacent

* *Elettricità*, Milan, Nov. 17, 1905.

Digitized by Google

mountains. The length of the canal from the intake to the turbine-house will be a little more than five miles, with a uniform gradient of 2 per 1,000. The width varies from 5ft. 3in. to 6ft., and the maximum depth for the water from 3ft. 9in to 4ft. 3in. There are in all eight tunnels having a total length of 4,500 yards, the shortest tunnel being 36 yards and the longest 1,740 yards; in five cases aqueducts will be constructed to carry the canal over rivers or streams. From the head-race two tubes are taken to the turbine-house, each of 3ft. 7in. internal diameter, with length of about 700 yards. For commercial and technical reasons the upper lengths of 270 yards are constructed of riveted sheets of thickness varying from $\frac{3}{16}$in. to $\frac{1}{2}$in., whilst the lower portions of the tubes are constructed of welded steel varying in thickness from $\frac{15}{32}$in. to $\frac{7}{8}$in. The upper part is anchored to the surrounding earth, and the lower portion is firmly supported by a masonry construction. The intermediate lengths rest on the rock-bed, supported at the joints, which are constructed with flanges and rings. The turbine-house is constructed on the left side of the River Dora, the total superficial area being 760 square yards; the floor is constructed above the maximum height that can possibly be attained by the river. The actual difference in level of the head-race and tail-race is 1,062ft.; an allowance of 12ft. is made for the pipe friction, leaving a net fall of 1,050ft., with a volume of 880 gallons per second. Taking the efficiency of the turbines at 75 per cent. there will be 12,800 h.p. available on the shafts of the hydraulic motors, which may be reduced in times of greatest scarcity of water to 8 500 h.p.

The most important machinery at the generating works will consist of seven turbo-generators, each 2,300 h.p., the three-phase alternators working at 4,000 volts and 50 periods; three other turbines, each of 200 h.p., coupled directly to exciters; seven transformers to raise the pressure to 40,000 volts; a comprehensive distributing switchboard and other accessories, including an overhead traveller for erecting or dismounting the machinery. The electrical energy will be transmitted to Turin, a distance of 37½ miles, by means of a double set of conductors carried on iron poles. The distributing centre will be established in the north-west district of the city, and will contain seven transformers, with necessary accessories, to reduce the tension to 3,000 volts.

It is intended to put down some steam plant in connection with this distributing centre, to be used in case of necessity when there is insufficient water to meet the requirements of the supply; the capacity of the steam plant will be determined at a later period. For the present a steam-turbine coupled direct to an alternator of 1,500 kw. will be put down.

The network in the city will consist of underground cables with auxiliary overhead conductors to distribute the energy to various points where large motors are required. At various points sub-stations are to be constructed from which local distribution will be effected. Taking account of the whole of the losses in the turbines, alternators, transformers, lines, etc., there results available energy of 8,000 h.p. at the consumers' premises, which may be reduced to 5,000 h.p. under the least favourable circumstances when the services of the steam-turbine would be required.

The estimates put before the municipality as a result of careful examination of the problem give the following results converted to English pounds: hydraulic works, £103,400; machinery at the generating station, £41,300; high-tension lines between Chiomonte and Turin, together with a telephone line, £39,600; distributing centre in Turin, £34 500; sub stations and distributing network, £128,000; purchase of concession, £13 200—total, £360,000. This estimate, however, is accompanied with the statement that the actual work will be carried out for somewhat smaller figures than the above. The estimate of working expenses, taking account of all the costs that may be introduced, are given at £42,500 per annum, equivalent to £5. 6s. per horse-power per annum, for the 8,000 h.p. available at Turin; or again, reckoning that 14 lamps of 16 c.p. can be lighted per horse-power, the cost works out at about 8s. per 16-c.p. lamp per annum.

The assertion is made that the future of Turin is essentially industrial; the small and medium-size industrial works have increased during the recent years at the rate of 500 h.p. per annum, and there is no reason to suppose that this rate of progress will cease, but rather that, by reducing the price of energy, it will be accelerated. At the present time the cost of energy per horse power per annum at Turin is put at £13. 10s. to £10, so that it may be said that the municipal project will reduce the cost by one half.

PLUMBISM DUE TO ELECTROLYSIS*

BY BALDWIN LATHAM, M.I.C.E., M.I.M.E., F.G.S., ETC.

There has recently occurred in the district of the South Hants Waterworks Company a case of lead-poisoning arising from the use of the company's water in a cottage on the Twyford Lodge estate at Twyford, Hants. The water supplied by the South Hants Waterworks Company is procured from wells in the chalk, one of their pumping stations being located at Timsbury, near Romsey, while the second pumping station is located at Twyford, about three-quarters of a mile from the place where the case of lead-poisoning has occurred. The water from both places is softened before being supplied to the public. The district in which lead was discovered in the water draws its supply from the Twyford pumping station, the waters of which are taken from a well and are softened with lime by the Haines' method. The waters are noted for their remarkable purity for chalk water, and are softened down to 4deg. or 5deg. of hardness before being passed into the mains of the district. The analysis of the water at Twyford, both before and after treatment, before the discovery of the lead in the water supply is given in Table A.

TABLE A.—Analysis of Twyford Water by Messrs. G. H. Ogston and Moore before and after Softening.

A letter bearing date Oct. 11, 1906, was sent to the secretary of the South Hants Waterworks Company by Dr. G. A. E. Roberts, of Twyford, the medical officer of health of the New Winchester Rural District Council, pointing out that in a sample of water taken from a cottage at Twyford there was a considerable trace of lead. He pointed out that the pipe, which was a ¾in. lead service, was rather long, but he said that he did not think that the water supplied by the South Hants Company had any solvent action upon lead, and asked Mr. Burnett, the secretary, if they knew of a similar case, and if he could account for it in any way, and he went on to state that an inmate of a cottage at the end of this lead service pipe was suffering from lead-poisoning. He said he had tested several samples of water from the cottage, and that there were traces of lead in it, even after a considerable quantity of water was drawn.

On Oct. 16 a piece cut out of the service pipe was sent to the author by Mr. G. Greenslade, the manager of the waterworks, which contained a white deposit. The manager also explained that the company's water near the end of the lead service was cloudy, but drawn from the same service near the company's main it was quite clear. The author was requested by the manager, if he thought necessary, to forward the sample of pipe to the company's chemists, Messrs. Ogston and Moore, with a view to ascertaining what was

* Paper read before the British Association of Waterworks Engineers.

Digitized by Google

the nature of the deposit, and this the author did in due course. A sample of lead pipe was also sent to the same chemists with a view to having the pipe itself analysed, and it was found to be perfectly pure lead. A sample of water taken from the house in which the case of plumbism had occurred was submitted to the chemists and was found to contain 0·14 grain of lead per gallon. The chemists reported at the same time that they had made a test with the company's water taken from the Twyford pumping station as to its effect upon lead, and stated: "We placed some pieces of pure lead in a small quantity of water (both the well and the reservoir), allowing them to stand for 24 hours, when they were tested for lead, but could find no trace of it. We repeated the experiment, but this time allowing them to stand for 48 hours. In this case there was the faintest trace, but not estimatable. We made another experiment, this time using composition pipe, but without result. The water had no action upon it. We may mention that side by side we made the same experiments with the water supplied to our laboratories here by the New River Company, and in each case found strong evidence of lead. We can only conclude on this evidence that the water supplied by the South Hants Water Company has no perceptible action upon lead, therefore the contamination must be looked for in other directions."

Subsequently the author made an inspection of the site in conjunction with the manager, and he reported to the directors of the company on Oct. 24 that after inspecting the site and considering the circumstances he was clearly of opinion that the presence of lead in the water was entirely due to electrolysis. The water service had clearly been attacked after passing the engine-house and storage batteries used on the place for the electric lighting of Twyford Lodge, and as the directors had been extremely anxious about the matter, and that it should be fully investigated, the author added: "You may feel confident that it is utterly impossible for water such as that which you supply to the district to have any effect whatever upon lead pipes, as water such as yours, which is alkaline is character, cannot by any possible means of itself become a solvent for lead—in fact, in all cases in which water has an action upon lead, the use of lime, such as you adopt in the softening of the water, is often the remedy prescribed."

It appears from the valuable investigation made by Dr. Houston, the present water examiner for London, that lead pipes are liable to attack by certain soft waters containing, as a rule, peaty acid, in which case the lead becomes dissolved in the water, and has produced dangerous illness among those using the water. Lead pipes are also subject to what he termed "erosion," which action bears no relation to the acidity of the water, in which case the surface of the lead disintegrates, and lead in a relatively insoluble form is deposited. It is the solvent action of water on lead that is the source of danger in drinking water. With regard to the "erosion" of the surface of lead, which is manifested chiefly on a bright surface, Dr. Power, C.B., F.R.S., of the Local Government Board, says that "erosion" is a factor not to be neglected, but is relatively of much less importance than the dissolving action of water upon lead. The analyst reported that the deposit in the lead service pipe was carbonate of lead, which, he stated, was no doubt formed by the action of water in the pipe, and said: "Your directors will undoubtedly wish to go further into this matter at once; therefore, to save time, will you please send us two pieces of leaden service pipe about 2ft. long, and two pieces of old pipe, besides the usual quantity of water, both from the well and from the reservoir, so that we may endeavour to find the cause of this action."

The samples of pipes were sent in due course, and the tests showed, as usual, that with the new lead pipe solvent action was perceptible which amounted to ·02 grain per gallon when allowed to remain in contact overnight, but on the second day the action was nil. The old lead pipe gave a rather larger quantity of lead. In the interval the chemists had received a communication from the author with regard to the position of the service pipe with reference to the electric cable and electric works, and stating his opinion that there was an escape of electricity, and that the action was due to electrolysis. The chemists stated that it was a very important and interesting point, and suggested that they should make some experiments at their laboratory, and report the final results of their experiments. In their report to the directors on the result of this experiment the chemists state that "we passed a current of electricity through the water contained in the pipe, allowing the action to go on over-night. In the morning the water was tested, and it was found a decided action had taken place, the activity having increased from ·005 to ·03; on the surface of the water we noticed some white powdery substance floating, and on the inside of the pipe several white patches had appeared. On examination, the powdery substance was found to be carbonate of lead, and we have no doubt the white patches are also carbonate of lead, which is beginning to form a crust on the inside of the pipe. We are of opinion, therefore, that the pipe in question is affected by its vicinity to the electric cable spoken of by Mr. Baldwin Latham, and that the corrosion of the pipe is entirely due to electrolysis."

At that time, having regard to the suggestion which had been made by the author that the action was due to electrolysis, it appears that Dr. Roberts discovered a feeble current of electricity from the tap in the house in which the case of lead-poisoning had occurred, and he also found it in other portions of the water company's district, and he communicated these results. The consequence was that the company determined to carry out a further investigation, and the directors instructed the author on Nov. 11 last to take immediate steps to trace the source of electricity in the pipes, on which he instructed Messrs. Lucas and Pyke, electrical engineers, of Westminster, to make an inspection of the premises and to test the mains at Twyford with a view to ascertaining what was taking place. On Nov. 14 they made a test at Twyford in the presence of the electrical engineer, of the owner of the property affected, and others. Messrs. Lucas and Pyke say in their report that the pipe in which the electrolysis had taken place was a lead pipe between 200 and 300 yards long, connected to the cast iron main of the water company. After it left the cast-iron main of the company, a branch from it was carried to Twyford Lodge, the residence of the owner of the property, and it then ran away in an opposite direction from the house in question, and passed near the engine-house where the electric plant supplying the current to Twyford Lodge is situated, and a branch water-pipe was carried into the engine-house, and the pipes continues thence, and is forked to supply two cottages, this latter portion of the pipe being a comparatively new pipe. It was in the most distant of these cottages that the case of lead-poisoning took place, the subject being a man who was said to be a water drinker.

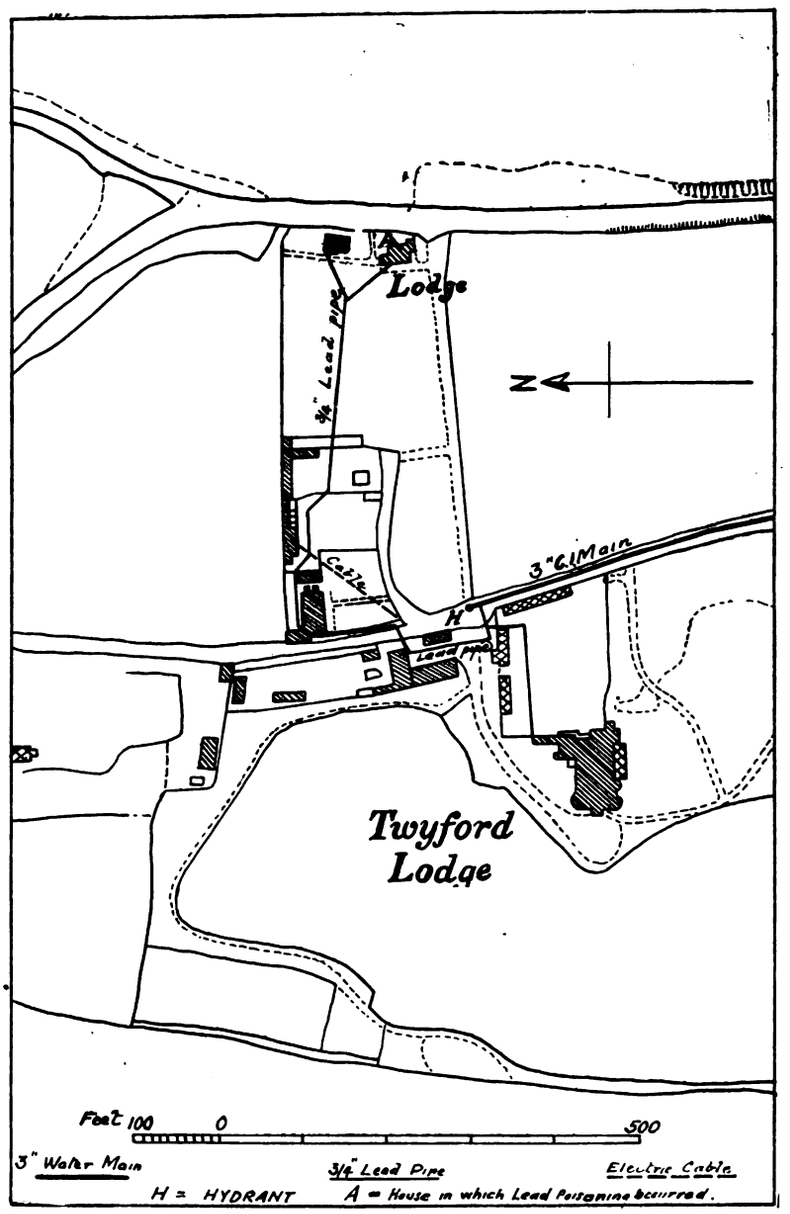
They reported that they were shown two sections of pipe, one removed from the older part of the pipe before it reached the engine-house branch, and the other from the branch pipe supplying water to the cottage in which the case of lead-poisoning had occurred, the latter of which showed a considerable deposit of what they understood had been ascertained to be carbonate of lead. The older section showed very little of this deposit, but, as might be expected, showed a strong deposit of oxide. In order to ascertain the possible source of leakage of electric current to these pipes, tests were made to find out any difference of potential between any section of the pipes themselves, and the pipes and the surrounding earth. The result of these tests was to indicate that the earth immediately under and round the engine-house showed a positive charge as compared with the pipes running away from this house, the isolated branch pipe supplying the engine-house showing the biggest difference when connected with the lead pipe that was continuous to the cast-iron main. The main was proved to be negative as compared with any part of the ground in the immediate vicinity of the engine-house. A distinct difference of potential was obtained, not of large amount, or exceeding 0·2 of a volt in any case, which Messrs. Lucas and Pyke state would not be sufficient in their judgment to account for the comparatively extensive electrolysis that had occurred, and they also state that it was clear, from the fact that the South Hants water-main was negative in every case, that the current could not have come from that direction. They, therefore, proceeded to examine the nature

Digitized by Google

of the installation supplying the current to the premises, and found that an earthed return system had been adopted. From the information obtained, and the inspection of what could be seen, it appeared that a copper uninsulated strip was run back from the engine-room to the house, which strip for a part of its run was enclosed in the same bitumen trough as the positive insulated main. There was no evidence of the strip having been properly connected to earth in the engine-house. A measurement of the resistance to earth of this nominally "earthed" return was taken, and it showed as high a resistance as eight ohms. Moreover, the potential of the ground immediately surrounding the engine-house was distinctly above that of the nominal earthed return main, but again not amounting to more than ·2 of a volt.

They observed also that the small leakages through the battery it is almost impossible to eliminate, and they expressed an opinion that they did not think them harmful.

On the discovery of the escape of the 1·8 volts of electricity into the lead pipe, the author communicated the fact to Messrs. Ogston and Moore, and they immediately instituted a further series of experiments, causing an electric current of 1·8 volts to pass through the water in a lead pipe, and on testing it found it to contain ·07 grain of lead per gallon. Two tests were made—in one case the current was allowed to pass through the water for the whole night, and in the other case for only four hours—and in each case the amount of lead subsequently found in the water was identical, so that it was amply demonstrated that a current such as that which was shown to be leaking from the electrical installation in question is ample to produce cases of plumbism, and may seriously affect all persons using such water supply. It is, therefore, of the utmost importance that water engineers should have a knowledge of this fact, so that in any case occurring within their own practice they may be able to effectually deal with the subject.



Up to this point the electrical engineers reported that the results obtained indicated a slight positive leakage round the engine-house, which occurred when the installation was completely cut off and no current passing through the mains, and was due to the creeping from the battery, and they did not consider that they had obtained sufficient evidence of a leak to account for the electrolysis. It, therefore, became necessary to seek for some other source of leakage, and the high resistance between the nominally earthed return and the earth itself seemed to indicate the direction of the leak. A test was then made with the house installation connected on, and a current of 30 amperes passing through the mains, when immediately an E.M.F. was detected between the earth return and the water-pipe running to the house of 1·8 volts, which in the engineers' opinion accounted for the whole trouble which had occurred.

The accompanying plan shows the position of the lead service pipe relative to the cast-iron main of the company, also the position of the electric cable. The lodge, marked A, is the residence in which the case of lead-poisoning occurred.

Wigan.—The Town Council have confirmed a resolution passed by their Electric Light and Tramways Committee to the effect that the Council contribute a certain sum towards the promotion in the ensuing session of Parliament of a Tramways Bill.

ELECTRIC MAINS FOR POWER TRANSMISSION WORK.*

BY PROF. JOHN T. MORRIS, M.I E E, MEMBER.

This paper is an attempt to present a brief account of some of the main theoretical and practical considerations which affect extra high-tension transmission, giving at the same time an account of various details of transmissions of this description which are in actual operation. It deals almost exclusively with the apparatus used for the actual *transmission* of currents at voltages of from, say, 5,000 to the maximum voltage that has been attempted for power transmission work.

Use of Direct and Alternating Currents.—Extra high-tension power transmission is usually carried out with three-phase currents, which system includes nearly the whole of extra high-voltage power transmission work. There are a few examples of direct-current, a few of single-phase, and a fair number of two-phase transmissions.

Effects depending on Current employed—Direct Current—Thury System.—In this system, as is well known, a constant current is maintained in the circuit, and variations in the load are dealt with by adjusting the voltage to suit. Usually, the current is transmitted by overhead wires, and it is only necessary to carry a single wire through each town or village on the route in which power is required, these all being linked upon a single circuit. The circuit returns to the station by a different route. This system has the advantage that the capacity and inductance of the circuit do not in any way affect the ordinary working of the line; also, of course, there is no trouble from losses due to lagging or leading currents. The following table gives the most notable examples of this system of transmission:

Direct-Current Power Transmission, Thury System.

	Max. volt.	H.P.	Length of circuit, miles.
La Chaud de Fonds	14,000	3,000	32
St. Maurice-Lausanne	23,000	4,600	35
Moutiers Lyons, in course of construction	60,000	6,000	114

Single-Phase System.—Up to the present time single-phase currents have been but little used for extra high-tension power transmission work, though it is quite possible that in the near future such currents may be employed, particularly at low frequencies.

Two-Phase System.—This system is adopted for power transmission work, but owing to the necessity of using in it a greater weight of copper and insulation than is required for three-phase work, transmissions on this system are not much favoured.

Three-Phase System.—At the present time this system undoubtedly holds the premier position for long-distance power transmission, chiefly because the weight of copper required is smaller than in any other alternating system, when the same voltage is the determining factor.

All alternating systems labour under the disadvantage of the possibility of increased losses in the line due to lagging or leading currents, also that any synchronous machinery is apt to be thrown out of step by a sudden short-circuit.

Overhead Mains.

Materials for the Conductor.—Practically only two materials are employed—hard-drawn copper and aluminium.

Copper.—American practice seems to show that up to 0·3in. diameter, solid hard-drawn copper wire is employed. Above 0·4in., stranded copper wire is almost always used. With regard to intermediate sizes, practice varies.

Aluminium.—Aluminium wire is usually stranded for the work, and is stronger than copper for the same conductivity, but the wind pressure is greater with aluminium owing to the greater surface for a given conductivity.

Wind Pressures.—Experiments conducted on a span 950ft. in length, supported on poles 45ft. high, give as a relation between velocity of wind and pressure on cable $P = 0{\cdot}0025\ V^2$ for a stranded cable, where P = pressure per square foot of projected cable area and V = actual velocity of wind in miles per hour. Apparently 65 miles per hour may be taken as a reasonable maximum for wind velocity if such exceptional events as tornadoes are left out of account. The following table gives some of the principal constants:

Properties of Aluminium and Copper.

	Aluminium.	Copper.
Elastic limit in pounds per square inch	14,000	40,000
Coefficient of expansion per degree C.	0 000023	0 0000173
Modulus of elasticity	9,000,000	16,000,000
Electrical conductivity	62 p.c.	100 p.c.
Specific gravity	2·68	8·9
Melting point	625deg. C.	1,080deg. C.

It will be observed that the expansion of aluminium is to that of copper in the proportion of 4 to 3, which means that if copper and aluminium wires of equal span are erected, there will be a greater sag in the aluminium span for a given rise of temperature. This fact, though not important as regards short spans, shows that with a long span the height of the poles for aluminium circuits must be greater. To quote an example of one of the longest existing spans, there is an aluminium line on the West Coast of America having a single span of 1,800ft.—rather over a third of a mile. It may be mentioned that steel is not very far from competing with copper and aluminium for long span work, particularly on account of its smaller coefficient of expansion, and also its greater tenacity.

Brush Discharge from Wires.—When the voltage on a bare wire in air is raised above a certain point, the wire becomes visible in the dark. The voltage at which this occurs is dependent on the diameter of the wire, as well as on the barometric pressure. The chief reason for the dependence of the brush discharge on the diameter is that the potential gradient—that is, the drop in volts per millimetre—passing away from the wire at right angles to the axis, will be greater for the smaller wire if the same voltage is applied in the two cases, owing to its radius being smaller. Signor Jona has determined the relation of the voltage for wires of different diameters at which brush discharge begins to occur, and he further notes that when all the wires are at the same potential, the outside diameter of the brush discharge is practically the same for each, which, to quote his own words, "is that diameter which reduces the potential gradient below the dielectric strength of air." The figures given in the recent British Association lecture delivered at Johannesburg by our vice-president, Prof. W. E. Ayrton, show very clearly the fact that once a wire has begun discharging in the air a further increase of voltage will increase very largely the brush discharge distance.

Pole Construction.—Poles are either made in wood, or some kind of wrought-iron or steel construction is adopted. It is practically essential for long spans to use the latter, on account of their greater strength and durability. There is, however, a drawback with regard to small steel towers, from the point of view of continuity of supply, which is, that should an insulator break and the wire fall, the line will have at once to be shut down, while with wood construction several minutes will probably elapse before a blaze is started which will short-circuit the line. Indeed, a case is known of a 40,000-volt three-phase circuit, with grounded neutral, where the wire lay on a dry cross-arm for several hours before the circuit could be switched over, and even in this case the cross-arm was not badly charred. It may be of interest to note that an extremely rough rule for giving the distance between wires is that the distance in inches is equal to $1\frac{1}{2}$ times the number of kilovolts used.

Loss in the Line.—A reasonable loss in the line is about 5 per cent. of the energy transmitted per 50 miles, though a smaller loss than this may well be obtained.

Insulators.—Porcelain and glass are practically the only two materials used for insulators. In some of the earlier power transmissions in the States, until about the year 1897, the insulators employed for voltages up to about 15,000 were formed and pressed in iron moulds, but this method of manufacture was rather apt to produce an insulator with flaws. On testing these insulators, it was found that the only part which was really effective for insulating was the glaze on the surface, and not the body. Now, however, American practice has reverted to making the insulators in pieces on the potter's wheel and separately glazing the parts, afterwards cementing them together either with sulphur or litharge and glycerine, or with Portland cement. The following are some of the main

* Paper read before the Junior Institution of Engineers.

Digitized by Google

points requiring attention in the design of high-tension insulators: there must be no flaws or cracks; the material should have a high dielectric strength; the surface leakage must be small, even when rain is falling, and the distance from the edge of the "umbrella" to the pin supporting the insulator must be sufficient to prevent arcs from starting; the mechanical strength also must be ample under working conditions. An unforeseen difficulty has been experienced in the use of white porcelain for the insulators in America—they form such an attractive mark for unscrupulous rifle shots! Brown porcelain and glass are much more generally employed now. One advantage possessed by glass is that a flaw can be at once seen. It is preferable to design the insulator in one piece, in order to distribute the electrostatic stress more uniformly throughout the insulator, but, as is generally the case in extra high-tension work, the insulator has to be built up of several pieces, and a cement should be used which has dielectric properties comparable with the component parts of the insulator. Glass is apparently better than porcelain as a dielectric, but has the serious defect of mechanical weakness. It would appear that this weakness is almost entirely due to internal strains which occur during manufacture. These strains can, of course, be greatly reduced by good design, and also by subsequent annealing. Specimens of various insulators are exhibited, including one suitable for 60,000 volts, and weighing 26lb.

Distribution of Electrostatic Stress in and around an Insulator when at work.—Take, for example, one of the insulators used in the Shawinigan-Montreal transmission line, which works at 53,000 volts three-phase, and consider as an extreme case 50,000 volts between the line wire and pole arm when rain is falling. The whole of the upper side of the "umbrella" will be at the same potential as the wire. If the potential gradient is too steep at the surfaces of the insulator, then a brush discharge will start from the edges, and this means that the surrounding air is rendered partially conducting, or is ionised, as it is called, which possibly will reduce the effective thickness of the dielectric, and this may cause a breakdown. It should be noticed that the intermediate voltages which the surfaces will assume will depend partly on the relative capacities of what may be looked upon as the condensers, which are electrically in series. It is obvious that these condensers are shunted by the surface leakage paths, but expert opinion in the States seems to incline to the belief that the surface leakage effect is in reality extremely small.* This is mainly due to the fact that at these extra high voltages surface leakage cannot permanently exist, since the conducting path will vanish, owing to the heat produced by the leakage current itself. As is well known, when conductors are connected in series, the voltage divides in the inverse ratio of their capacities.

Burning of Pins.—Pins are usually made either of locust, oak, or eucalyptus wood, carefully treated so as to exclude moisture. Iron pins are also largely used. After a line has been in operation for some months, the pins carrying the insulators, if of wood, are sometimes found to have a charred appearance. This is caused by a discharge, which can be seen at night, and which produces an appreciable sound. This charring effect is practically absent below voltages of 20,000, but at 40,000 becomes a factor requiring serious attention. Opinions differ as to the cause of this burning of pins. Some authorities consider it to be due to surface leakage, whilst others attribute it to the effect of a brush discharge between the inner part of the insulator and the pin. Undoubtedly, however, this effect has to be reckoned with, as in some lines pins have had to be replaced two or three times in a year. Iron pins are much better from a mechanical point of view, but the attachment of the insulator to them requires care. The iron pin may be enlarged at its upper end, and then fixed in the insulator by means of lead or cement. Or, the metal pin may have a wood sleeve having a thread on its outer side, and the insulator may be screwed on to this pin, as in the Locke insulators, specimens of which are on the table. It may be of interest here to refer briefly to some troubles peculiar to overhead work which have actually been experienced in America. These are of various kinds, such as lightning actually striking the line; insulators destroyed by being shot at, as previously mentioned; loose pieces of bare wire being thrown at the line by reckless "experimenters"; cranes or geese flying into the line; green hay carried by the wind; an engine starting up under the line, etc.

* Exceptions must be made in the case of lines close to the sea-coast, where the salt in the air gets deposited on the insulators, also in the neighbourhood of chemical factories, and under other special conditions.

Underground Mains.

Insulating Material.—For underground main work there are practically only two kinds of insulating materials which can be employed. These are rubber and paper.

Rubber.—Rubber is seldom used for this extra high-tension work on account of its great expense, though it has a very high dielectric strength. If well vulcanised and kept free from brush discharges in air and not alternately wetted and dried, rubber is said not to deteriorate appreciably with time.

Paper.—A good manilla paper is chosen for this purpose. It should be laid in thin and regular layers round the conductors. The layers must neither be wound on too tightly, which would sacrifice flexibility, nor too loosely, as there is then risk of the paper insulation crumpling. After the winding, the cable must be properly dried in a vacuum (at a *moderate* temperature, otherwise the paper would become brittle) and afterwards impregnated with some form of resin oil, which will not harden with age.

Insulation Resistance.—Formerly the insulation resistance of a cable was regarded as the most important factor to be taken into account. Nowadays, however, it is almost left to take care of itself, and instead, attention is directed to breaking-down strength and bending tests, and, after the cable is laid, to its withstanding about double the ordinary working pressure for a period of an hour. It is of interest to note that if the temperature of an impregnated paper cable be raised 20deg. C. the insulation resistance will fall to one-thirtieth part of its previous value—an enormous reduction—but, fortunately, one which does not appreciably affect its breaking-down strength.

Dielectric Strength and Specific Capacity.*—Signor Jona gives the following data for dielectric strength and specific capacities as good working averages for materials used in cable manufacture:

Dielectric strength of rubber in lengths on cable—
12,000 to 15 000 volts per millimetre.
Dielectric strength of paper in lengths on cable—
8,000 to 10 000 volts per millimetre.

Specific Capacity of Various Materials.

Paper cables	3–4
Paper	about 2
Resin	2–3
Mixtures used for impregnating	3–4 or above
Pure vulcanised rubber, about	3

The addition of certain materials to rubber raises its specific capacity without appreciably altering its dielectric strength. The following table gives facts relating to some of these mixtures as compared with pure vulcanised rubber.

				Sp. capacity
Pure vulcanised rubber				about 3
Per cent.	Per cent.	Per cent.	Per cent.	
58 Para ...	2 sulphur ...	26 talc ...	14 zinc oxide ...	4–4 2
40 " ...	5 " ...	55 carbonate of lime	...	4·6
64 " ...	8 " ...	16 talc	... 4 zinc oxide 8 per cent. minium ...	5·
56 " ...	22 " ...	22 " ...	— ...	6·1

Arrangement of Conductors.—A three-phase cable consists, as is well known, of three cores of copper equally spaced inside a lead sheath, and approximately the thickness of the dielectric between any pair of cores and between any core and the lead sheath is equal. The application of theoretical considerations to cables of this section is by no

* Two terms are in common use to denote this quality: dielectric constant and specific inductive capacity. The author regards the former as unsuitable, as it might equally well be applied to the dielectric or breaking-down strength. Further, is it not a misnomer, since the "constant" in many cases varies for a given material? The latter term, specific inductive capacity, seems unsatisfactory, as it contains the word "inductive," which tends nowadays rather to confuse than elucidate the idea. In view of this consideration the term specific capacity would appear to be preferable, though it still is open to the objection that "specific" should refer to a property of a body which is independent of its dimensions.

Digitized by Google

means easy, but some light will be thrown upon it by a study of the simpler case of a concentric cable. Take the case of a concentric cable, in which

r = the external radius of the inner conductor in millimetres;
R = the internal radius of the external conductor in millimetres;
x = the radius in millimetres at some point r and R;
V = volts between r and R.

Then it can be shown that the drop in volts per millimetre—*i.e.*, the potential gradient—is given at any point by the expression

$$\frac{\cdot 434\ V}{x \log_{10} \frac{R}{r}}.$$

Which means that in a concentric cable the electric stress each layer supports in inversely proportional to its radius, or the potential gradient is in the inverse proportion of the electric capacity of each layer. This implies that in this case the dielectric is not uniformly stressed, the inner layers being more highly stressed than the outer. In some cases the stress on the inner layer may be as much as four times that on the outer. A stranded wire as compared with a solid wire of the same section will always have a greater potential gradient very close to the surface of the conductor, owing to parts of the outlines of the section of the conductor having more sudden curves. It is for this reason that Signor Jona, in attempting to construct a single-core cable for an extraordinary high voltage, adopted the bold expedient of encasing the stranded wire with a thin sheath. This cable is described in the next section of the paper.

Examples of Cables.—Originally a three-core cable was made by taking three stranded cores, each of *circular* section and each insulated separately, and combining the three into a single cable, the interstices being filled in with jute or some other material until an external circular surface was obtained. This was then further covered with insulation, and a lead sheath tightly enclosed the whole. The disadvantage of the arrangement was that the dielectric was by no means uniformly stressed, and hence for a given breaking-down strength and section of core the diameter of the finished cable was unnecessarily large. A specimen is shown of a Henley 6,000-volt three-phase cable, each core 0·15 of a square inch, supplied in 1899. Within the last three or four years the above design had been modified in the majority of extra high-tension three-phase cables in this country, which now have cores of a 120deg. sector shape in place of the circular, the three corners being more or less rounded. This results in making the dielectric stress more uniform, owing to the fact that the dielectric is more uniform in thickness between the cores and also between each core and the sheath. In the recently introduced so-called "Laminæ" Henley cable, this idea is even more perfectly carried out. Lead sheathing is naturally fairly fusible and not of very great conductivity, and it is conceivable, though unlikely, that a severe short-circuit might result in a portion of the lead sheathing assuming a considerable difference of potential with respect to the earth in which the cable is laid, which might cause more than unpleasant surprises to passers-by! To minimise the risk, the Board of Trade has favoured the introduction of a number of thin copper strips placed directly beneath the lead sheath; the object being to increase the conductivity and diminish the fusibility of the sheathing as a whole. Occasionally, as in some of Callender's mains, the internal copper sheathing is replaced by external galvanised armouring, in direct contact with the lead sheathing.

It is interesting to note the various means employed by manufacturers to diminish the lost space due to the section not being quite filled with copper as, for example, the "hammered" sections, B.I. and H.C.; the introduction of a few wires in the strand of different diameters, as in Siemens; and the almost complete use of the space, as in the Henley "Laminæ" cable. Another cable of special interest from the point of view of insulation is that referred to above, designed by Signor Jona, of Messrs. Pirelli, Milan. It is a single-core cable, having, as previously mentioned, a thin lead sheath encasing the stranded conductor, and has graded insulation from the inside outwards. This has the effect of giving a more uniform distribution of potential gradient. There is first a layer of dielectric of specific capacity 6·1, then a layer of specific capacity 4·7, then one of specific capacity 4·2, and, finally, a layer of specific of 4·0, over which the ordinary lead sheath is placed. This particular cable has successfully withstood a pressure of 150,000 volts for one hour. For further information on the principles underlying this grading of insulation, members are referred to two standard papers on this subject: "Insulation on Cables," by M. O'Gorman; "Insulating Materials in High-Tension Cables," by E. Jona.

Energy Losses in Cables.—By far the greatest loss in cable is due to the resistance of the conductors. The various losses may be stated as follows: ordinary C^2 R losses in conductors, eddy-current losses in conductors, eddy-current losses in lead sheathing and copper strips, increased eddy-current losses due to iron armouring, energy losses in the dielectric. From some tests made a few months ago by the author, at the East London College, it was shown that in a particular sample of an ordinary stranded three-core cable having 0·1 square inch section per core working on a supply at a frequency of 50 cycles per second at a current of 100 amperes per core, the eddy-current core loss is 2·1 per cent. of the ordinary C^2 R loss, and the lead sheath loss is about 1·2 per cent. of the ordinary C^2 R loss. This sample has no copper strips nor iron armouring, both of which would have some effect in increasing the total loss. If the energy losses be taken into account in the dielectric as well, it seems probable that the total increase of the losses in a three-core cable supplied with three-phase currents might be some 6 to 10 per cent. in excess of the ordinary C^2 R loss. This, however, is relatively unimportant when compared with the total power supplied by a transmission, as the transmission losses themselves are of the order of 5 per cent., while these minor losses are not greater than 10 per cent. of this 5 per cent., which means only ½ per cent. of the total.

Heating of Cables.—When current is flowing in the conductors of a cable, heat is developed at a certain rate. Since the greatest care is taken to electrically insulate the conductors, they are in consequence remarkably well insulated thermally—that is, heat cannot be rapidly dissipated from them. This results in a prolonged though gradually diminishing rate of rise of temperature during the passage of a current of constant value, until a steady temperature is finally obtained. This steady condition would not be reached in ordinary cables until after the lapse of some hours. In consequence, a rise of 20deg. or 30deg. C. or even much more may be quite common. The initial rate of rise in temperature of a copper cable is practically determined by the current density employed, and will be approximately proportional to the square of the current density. At 1,000 amperes per square inch the initial rise, if no heat were lost, would be at the rate of about 0·75deg. C. per minute, so in any practical cable the rate of rise cannot exceed this figure for the same current density, but will be less by an amount depending on the construction of the cable.

(To be continued.)

LEGAL INTELLIGENCE.

TRAMWAYS AND TREES.

The record was closed recently in an action at the instance of Wm. Kinross Gair, writer, Falkirk, against Messrs. Bruce Peebles and Co., East Pilton, Edinburgh. The pursuer concluded for £100, and avers that it was not necessary for the construction of the tramways authorised by the Falkirk and District Tramways Order Confirmation Act, 1901, that defender should lop the pursuer's trees overhanging on the Camelon-road so closely as they did, and the lopping was more extensive than the pursuer was by the defenders' letters led to believe, and to the extent to which it was unnecessary it was wrongful and illegal. Moreover, the work was conducted in a careless, unskilful, and untradesmanlike manner, and with a total disregard of the pursuer's interests. The stumps of the branches were left in a torn, damaged, and undressed condition. The trees were disfigured, their

Digitized by Google

value as timber substantially reduced, and the ornamental effect of the plantation seriously diminished. The pursuer further averred that by the said operations the defenders had seriously injured the amenity and privacy of his property by depriving to a large extent the shelter and screen afforded by the trees.

The defendants in their defence state that they sub-contracted with the British Electric Equipment Co., London, for the execution of the work relating to the overhead electrical equipment. The work of lopping the trees along the road was necessary, and was not included in the sub-contract, but was made the subject of a subsequent separate order by the defenders to the Equipment Co. The defenders communicated to the Equipment Co. correspondence which took place between pursuer and defenders and the proprietors of the ground fronting Camelon-road. The defenders deny that the operations of lopping off the branches in question were carried out by them, but, on the contrary, were entirely carried out by the said British Electric Equipment Co. The defenders aver that the work was carried out carefully. No lopping was done except in cases where it was absolutely necessary. The defender further averred that the pursuer was well aware that the operations were carried out, not by them, but by another firm, and that the operations were extended in virtue of powers conferred by Parliament upon the Falkirk and District Tramways Co.

Parties' agents were heard in debate in the Sheriff Court on the 18th inst. on the preliminary pleas stated for both pursuer and defenders, and Sheriff Moffatt made *avizandum*.

SOUTHPORT TRAMWAY ACCIDENT.

An action was heard in the Southport County Court before his Honour Judge Collier on the 19th inst., in which Messrs. Peter Rigby and the Southport Carriage Co. sued the Southport Tramway Co., the action being for damages in respect of a collision due to the negligent driving of the defendant company's servant between one of the plaintiff company's cabs and one of the defendant company's tramcars.

Evidence in support of the claim was to the effect that the tramway gong was not sounded, or that the tram, considering the locality, was going at too great a speed, and that the driver had not his brakes under control, or did not put them on in sufficient time.

The defence denied negligence, but the jury found for plaintiffs, and his Honour awarded them £15 damages.

COMPANIES' MEETINGS AND REPORTS.

BURMA ELECTRIC TRAMWAYS AND LIGHTING.

The annual general meeting of the shareholders of this Company was held on the 21st inst., Mr. E. C. Morgan (chairman) presiding.

The CHAIRMAN said that the accounts submitted covered a full year's working from Aug. 1, 1904, to July 31, 1905. Turning to the revenue account, he observed that the traffic receipts amounted to the respectable sum of £13,777, received from 2,807,287 passengers on a mileage of 553,494 car miles. On the other side they had spent £11,329, which leaves a surplus on the year's working of £2,457, or about 2½ per cent. on the preference shares. This sum, however, is not at present divisible, said Mr. Morgan, as it is fully employed in stocks and stores in hand. Under the head of power expenses fuel figured for the large sum of £2,075. You are no doubt aware, continued Mr. Morgan, that at present we are obliged to keep our furnaces going with wood, which is the only fuel available. This is not only dear, but is also a wasteful form of fuel, as the consumption is necessarily greater than that of coal. I may say, however, that our inquiries have been consistently directed to obtaining a better and cheaper fuel, and we are now informed that we may shortly expect to obtain good coal from fields which are being exploited on the Chindwin River, not very far from Mandalay, which are said to contain large quantities and of good quality. If these representations are realised, we may confidently anticipate to make a considerable saving on the amount paid for fuel. I may mention that the charge of £750 for directors' fees, though not large in itself, seems perhaps more than the undertaking at its present stage can fairly bear, and the directors resolved at a Board meeting in October last that until the full dividend on the preference shares is earned they will limit their drawings to £500, such reduction to take place from the commencement of the current year. As regards the general outlook, Mr. Morgan said that the traffics are now showing appreciable and satisfactory increases, and they trust that these will be maintained and tend to further expand. So far, said the chairman, I have dealt with our existing system, but our inquiries lead us to believe that we may profitably increase this system. Our present lines, you will recollect, form more or less a "T," with the Zegyo Bazar as the centre, whence lines radiate to the east, west, and south. We have, however, no line at present running north of Zegyo, which, whilst, perhaps, less densely populated than the other points, still serves a very considerable population, not only of actual residents, but of people coming in from the northern suburbs. Although we are not yet quite certain as to our facts, I may say that the conviction is being forced upon us that we should derive great advantage by constructing a line from the Zegyo Bazar, Northwood, to the municipal limit. This, of course, would entail the outlay of further capital, but the outlay would be quite moderate, as it would only mean the construction of permanent way and overhead lines and feeders, our existing power plant and cars being sufficient to undertake the needful service. If this scheme is carried out it would, of course, be necessary to raise further money, and this must be in the form of debentures ranking in front of the preference shares; but we should only recommend such a course if we were reasonably convinced that it would add materially to the value of the preference shares, by securing more quickly their full dividend after payment of the debenture interest. I am not prepared to-day to make any recommendation; but I think it right to mention the matter, so that it may receive your consideration, and that you may be prepared to deal with our proposals if and when they are made. In conclusion, I may say that we have every reason to be satisfied with our plant and equipment, which are of the best quality and do their work admirably. The only difficulty we have had has been the somewhat inadequate traffic hitherto secured; but this is apparently disappearing, and there is reason to hope that with a little patience we shall find ourselves in possession of a property of increasing value.

The report was adopted.

PROVINCIAL TRAMWAYS.

The annual general meeting of this Company was held at the offices on the 22nd inst., Mr. Andrew Beattie presided.

The CHAIRMAN, in moving the adoption of the report (copy of which appeared in our last issue), said that the Company had not been successful in getting their Bill for an extension of the Grimsby tramway system approved by the local authorities. There had been unavoidable delays in opening the Gosport and Fareham tramways, but the inspection by the Board of Trade was taking place that day, and they hoped that the lines would be opened for traffic in the course of a few days. On the question of reducing the nominal value of the ordinary shares the directors had circularised the shareholders, and there had been a large response, but there was still a considerable percentage of the shareholders who had not answered either way. The directors would take no steps in this matter without a deliberate and definite mandate from an overwhelming majority of the shareholders. They did not want to court litigation from any shareholder who disapproved.

Mr. SAMUEL HERN seconded the motion, which was carried.

Special resolutions were afterwards passed to authorise the Company to supply electric energy for power and lighting in the districts of Fareham, Gosport, and Alverstoke, and to adopt the provisional order granted by the Board of Trade to the Gosport and Alverstoke Electric Lighting Co.

DELAGOA BAY DEVELOPMENT.

The annual meeting of this Company was held on the 20th inst.

Mr. J. C. A. HENDERSON, who presided, said that their business was in a development stage, and its growth must depend on the growth of the port. With regard to their telephone system, there was not much to say except that the present switchboard was full. The directors did not feel prepared to incur any outlay for enlarging it until the concession was placed on a more satisfactory basis, and negotiations with that object were now being carried on with the authorities. Respecting the electric tramways, he observed that at present these were the least satisfactory of their various undertakings. A scheme for enlargement was, however, under consideration, from which, he said, better results might be looked forward to. The companies' total earnings for the year were £31,432 and the expenses £38,399, leaving a loss of £6,967.

The report was adopted.

LIENS REGISTERED.

Webster Electrical Engineering Co., Limited, Bradford.—Lien registered Dec. 13 for £375 6 per cent. debentures, part of £1,000; amount previously issued, £625 No trustees. Charged on the undertaking property, and uncalled capital.

Electrolytic Alkali Co., Limited, Middlewich.—Lien registered Dec. 8 for £300 4½ per cent. debentures, part of £50,000; amount previously issued, £20,850. Trustee: Liverpool Mortgage Insurance Co. Charged on the undertaking and all the property, including the uncalled capital.

W. T. Henley's Telegraph Works Co., Limited, London, E C.—Trust deed registered Dec. 13, for securing £300,000 4½ per cent. first mortgage debenture stock. Trustees: Right Hon. Sir A. C. Lyall, 18, Queen's-gate, S.W., and H. L. M. Tritton, 54, Lombard-street, E C. Secured by a first charge on the freehold works at North Woolwich and Gravesend and the leasehold offices of the company, and by a floating charge on the undertaking and all other property.

PERSONAL.

Mr. A. Hugh Seabrook having been appointed engineer and manager to the West Ham Corporation electricity supply, the Urban District Council and officials of Barking, together with the electricity consumers in the town and neighbourhood, last week at a special meeting of the Council marked their appreciation of his services during the five years in which he has occupied the position of engineer and tramways manager by presenting him, on behalf of the Council and officials, with a handsome gold watch, suitably inscribed, and with a vellum testimonial which reads as follows:—"Urban district of Barking Town, in the county of Essex. To Mr. A. Hugh Seabrook, electrical engineer and tramways manager, Barking: The Urban District Council of Barking Town have received with regret your resignation of the position you have held as electrical engineer and tramways manager of the Council upon your preferment to the important and responsible position of electrical engineer to the

Digitized by Google

county borough of West Ham. They desire to congratulate you on your well-deserved promotion, and to express to you their appreciation of the manner in which you have discharged the duties that have fallen upon you whilst in their service. You have acted as electrical engineer for a period of nearly five years with conspicuous ability, and during that time have shown yourself to be an expert electrician, which combined with your knowledge of the working of a generating station, the laying of mains, etc., and the management of workmen, have proved of great value to the Council. The period during which you have acted as head of the electricity department has been a most anxious and trying one, and you are to be congratulated upon the fact that the undertaking, which upon your appointment showed a loss of over £1,000 per annum, has, under your management, become more than self-supporting. You have the best wishes of the Council for continued success in your future career.—Given under the seal of the Council this 28th day of November, 1905, J. Wilson (chairman of the Council), H. Hargreaves (clerk of the Council)." Mr. H. J. Mackrow (general manager to Messrs. Page, Calnan, and Co.), on behalf of the chief consumers in Barking, presented a handsome silver-mounted spirit tantalus to Mr. Seabrook and an elegant cut-glass silver-mounted scent bottle to Mrs. Seabrook.

We have been asked to state that Mr. D. G. Sutherland, who for the last five years has held the important post of chief engineer of Messrs. Bruce Peebles and Co.'s contract department, will resign his position at the end of December to become partner in the old-established firm of engineers, Messrs. Mitchell Graham and Son, 46, Buccleuch-street, Edinburgh, and that electrical and mechanical engineers are invited to forward lists and catalogues to him at this address.

We are informed that Mr. F. E. Mackee, who has been with the British Insulated and Helsby Cables for nearly 11 years, has started business with Mr. O. M. Robinson at 13, Castle-street, Liverpool.

Mr. Sharp, who has acted as construction superintendent and clerk of the works at the Brighton Corporation's Southwick station, has been appointed superintendent, and his salary has been increased from £4 to £5 per week. Mr. G. Claughton, who has been acting for the Westinghouse Co., is to be assistant superintendent at £4. 10s. per week. Three high-tension switchgear operators are to act as shift engineers at £2. 10s. each. The salary of R. Tonge, foreman fitter, has been raised from £2. 2s. 6d. to £2. 10s. per week, and that of F. W. Markwick, boiler-house foreman, to £2. 10s. per week.

NEW COMMITTEES.

GRAVESEND.—*Electrical*—Councillor Enfield, chairman.

KING'S LYNN.—*Electricity*—Mr. Gemmell, chairman.

LOWESTOFT.—*Electric Lighting*—Councillor Fry, chairman.

STOKE ON TRENT.—*Electricity and Destructor*—Councillor Yoxall having declined the office of vice chairman, Councillor Brooke has been appointed.

WALSALL.—*Electricity*—Alderman William Brownhill, chairman; Alderman Noake, vice-chairman.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Pontypridd.—The Urban District Council invite tenders for cable conduits. Tenders to the Clerk by Jan. 1.

St. Marylebone.—The Electricity Supply Committee invite tenders for house service fuse-boxes. Tenders by Jan. 10. See advertisement.

St. Marylebone.—The Electricity Supply Committee invite tenders for various stores. Tender by Jan. 10. Full particulars in advertisement columns.

St. Pancras.—Tenders are invited for supplying (Section A) arc lamp columns and cradles; (B) open-type arc lamps. Tenders by noon on Jan. 9. See advertisement.

Leyton (Essex).—The Urban District Council invite tenders for the construction of nine miles of double tramway track, and for all materials connected therewith. Tenders by 7 p.m. on Jan. 8.

Aberdeen.—Tenders are invited for six tramcar top-deck covers. Tenders to Mr. J. Bell, city electrical and tramways engineer, Electricity Works, Aberdeen, by noon on Jan. 6. See advertisement.

Croydon.—The Guardians invite tenders for the installation of electric fire-alarms at the infirmary. Tenders to Mr. H. List, clerk, Union Offices, Mayday-road, Thornton Heath, by 4 p.m. on Jan. 8.

Madrid.—The Public Works Department require tenders for a concession to construct and work an electric tramway between Santander and Astillero. Guarantee, 8,195 pesetas. Tenders by Jan. 30, 1906.

Gravesend.—The engineer has been authorised to forward specifications to a number of firms asking for tenders for economisers to be submitted to the town clerk so as to be available for committee during January next.

Manchester.—Tenders are invited for laying underground telephone pipes, with other appurtenant works. Tenders to the Chairman of the Special Committee re Telephones, City Surveyor's Office, by 10 a.m. on Jan. 2.

Launceston (Tasmania).—Tenders are invited for the supply of 500 or more electric meters and for maximum demand indicators. Tenders to Mr. C. W. Rocher, town clerk, Town Hall, Launceston, Tasmania, by 12 noon on Jan. 15.

Rochdale.—The Electricity Committee invite tenders for the supply of cables. Firms wishing to tender are requested to make application on or before Jan. 1 to the Borough Electrical Engineer, Electricity Works, Dane-street, Rochdale.

Grimsby.—The Corporation require tenders for contracts contained in Specifications No. 35-39 and 43-45, for electrical plant, cables, and buildings. Tenders by Jan. 5, 1906.

Sofia (Bulgaria).—Tenders are invited for the electric lighting of the Government Cadet School. Tenders by Jan. 19. Offers must be addressed in the Bulgarian language and be accompanied by a deposit of 5 per cent. of the amount of the tender.

Spain.—The *Gaceta de Madrid* contains a notice inviting tenders, which will be opened at noon on Jan. 30 at the Directorate-General of Public Works, Madrid, for the concession of an electric tramway between Santander and Astillero. A deposit of about £208 is required to qualify any tender.

Brussels.—Tenders are required for the electric lighting of the marine hospital. Conditions may be obtained from the Secrétaire général de l'administration des hospices et secours de la ville de Bruxelles, Boulevard du Jardin botanique, hôpital St. Jean, Brussels. Tenders by Jan. 5, 1906.

Cardiff.—With regard to the contract for the electric wiring of the new asylum at Velindre, Whitchurch, it has been decided to ask the six firms whose tenders were lowest when the contract was first advertised to send in fresh tenders on the old specifications, and that the successful tenderer be debited with the value of the work done by Messrs. Firth and Sons.

Southport.—Tenders are to be obtained by the Town Council for the supply of a battery of accumulators and a booster to be worked in connection with the traction sets; a shaping machine is to be purchased for the workshop; and the electrical engineer has been instructed to rewind the field magnets of three alternators as soon as convenient, and to provide an atmospheric exhaust to the No. 3 traction set.

RESULTS OF TENDERS.

Burslem (Staffs).—The Town Council have accepted the tender of E. M. Evans, at £104. 17s., for lighting St. John's Market by electric arc lamps.

Paddington.—The Metropolitan Electric Supply Co. have been awarded the contract for re-wiring the existing portion of the town hall and for the electric lighting installation of the whole of the new building at £636.

Tokio.—We hear that C. A. Zadig and Co., engineers and contractors, of 73, Queen Victoria-street, London, E.C., have secured an order for 200 miles of portable railway and 240 switches for the Japanese Government.

Car Contracts for London Tube Railways.—According to the *Railway Times*, the contract from the London Underground Electric Railways Co. to the American Car and Foundry Co. for the whole of the steel cars for the Charing Cross, Euston, and Hampstead Railway has now been supplemented by the statement that the number of these cars is 150, of which 60 are motorcars and 90 are trailers. The builders of the cars will also construct the trucks. The Underground Railways Co. have also awarded contracts to French and Austrian firms for the steel cars required for the Great Northern, Piccadilly, and Brompton Railway. The number of these cars is 216, of which 72 are motorcars and the remainder are trailers. The firms which have obtained the contracts are Les Ateliers de Construction du Nord de la France, Blanc Misseron, and the Hungarian Railway Carriage and Machine Works, Raab. These firms will also construct the trucks.

BUSINESS NOTES.

Mansfield.—There has been an increase of 11,300 units generated during the last month.

Southport.—The Corporation's engineer has been instructed to lay down a telephone cable to the sewage-disposal works.

Leyton.—The Urban District Council intend to apply for sanction to borrow £21 000 for extensions to the electric power station.

Alexandria (Dumbartonshire).—A town's meeting has decided in preference of having electric tramways over motor-omnibuses

Weston-super-Mare.—The electric light failed for a short time on Saturday owing to an accidental discharge from the storage cells.

Ross (Herefordshire).—The electric light and power company are putting down a new 100 h.p. direct-coupled set at their works here.

Southend.—The engineer is to lay mains to consumers at a cost of £460 in addition to the £1,902 in Alexandra-street and Leigh-road.

Kilkeel.—The Sanitary Committee of Rostrevor have been asked to furnish the Council with details of the proposed electric lighting scheme.

Llanelly.—The Llanelly Chamber of Commerce will oppose at the forthcoming inquiry any proposals to increase the indebtedness of the town on electric lighting.

Abercarn.—The District Council have decided to apply for a provisional order to enable them to supply electricity for all public and private purposes throughout the urban district.

Wantage.—We learn that the Wantage Engineering Co.'s works, Berkshire, were partially destroyed by fire on Saturday. The main building, containing a large electric light installation, was saved.

L.C.C. Tramways.—Colonel Yorke conducted the Board of Trade inspection of the section between Aldwych and the Angel yesterday in the presence of a representative gathering of municipal authorities.

Torquay.—At the last Town Council meeting the offer of the National Electric Construction Co. to lease or purchase the electric lighting undertaking was discussed. An amendment not to entertain the offer was carried by 15 to 14.

Digitized by Google

Dunfermline. — The Electric Lighting Committee have been instructed to continue negotiations with the Fife Electric Power Co. re the proposed agreement, and to invite Messrs. Crossley, Birmingham, to meet the Council in committee.

Rickmansworth.—The Rural District Council and Parish Council have passed resolutions protesting against the granting of an electric lighting order in the district. The County Council suggest the better plan would be for the local authority themselves to apply for an order.

Midlothian.—The County Council have passed resolutions to oppose, so far as affecting the county of Midlothian, the Edinburgh Corporation provisional order, the Edinburgh and Queensferry Tramways provisional order, and the Inveresk electric lighting provisional order.

"Useful Hints."—Under this title the electricity department of the Sutton Coldfield Corporation, of which Mr. Trevor Duesbury is the engineer and manager, have issued a well got-up pamphlet which gives all the information a consumer, and those who desire to become such, need require.

Perth.—At the last meeting of the Electricity Committee of the Town Council a letter from Mr. Duncan Cumming, sanitary inspector, was read, drawing attention to the alleged smoke nuisance at the electricity station. A special committee was appointed to inquire into the whole matter and report.

Bootle.—A small mishap occurred at the Corporation electricity works last week, when, owing to a short-circuit, one of the new dynamos caught fire. There was a loud explosion, and big blue flames shot up. The dynamo was damaged, but the town's electricity supply was cut off only for about 20 minutes.

Seaham.—Notice has been given to the local authorities concerned by the Seaham, Murton, and Hetton Tramways Syndicate of its intention to apply to the Board of Trade for a provisional order to distribute electricity for motive power and all public and private purposes within the urban district of Seaham Harbour.

Glasgow.—The Glasgow Corporation tramways department have paid £43 784. 7s. 1d. of taxes this year, as compared with £38,781. 15s. 9d. last year. Of the former amount £791. 11s. 7d. is for water, £14,955. 12s. 8d. to Glasgow, £1,533. 10s. 9d. to other burghs, £21,947. 2s. 6d. to parishes, and £4,556. 9s. 7d. to counties.

Southampton.—The Town Council have adopted the recommendation of the Tramways Committee to proceed with repairs to the Shirley route. The issue of books of tickets will be discontinued on and after Jan. 1 next, having regard to the small percentages of passengers using the same, and also the loss sustained by the committee on the sale of such books.

Burnley.—The Town Council have adopted the borough electrical engineer's report to fuse the lighting network by means of disconnecting fuse pillars into five areas, at an estimated cost of £450. The above will meet the requirements of the Board of Trade regulations, and reduce a total failure in the supply due to a fault on the mains to a minimum.

Kingston (Surrey).—The Town Council have agreed to supply a large consumer with current for motor power at 1½d. per unit, on condition that there be a minimum payment of £150 a year for seven years. The Lighting Committee have also decided to reduce the general rate for current for motor power, cooking, and heating to 2d. per unit after March next.

Handsworth (Birmingham).—At the last meeting of the District Council it was stated that close upon £50,000 had been spent in erecting and equipping the electric lighting station, and that the time had arrived for the adoption of a tramway scheme for Handsworth. Notice has been given to bring this matter before the Electric Lighting and Tramways Committee.

Dundee.—A deadlock has arisen between the Town Council and the Broughty Tramway Co. in the matter of fares for the through journey. Negotiations between the parties have so far been devoid of agreement, and the result is that, failing agreement in the meantime, when the suburban line is opened each party will charge its own fares, the through journey costing the burgh plus the company's rates.

Brighton.—The electrical engineer having reported that he had been unable to arrange with the railway company to supply them with electricity, and that one of the two new feeders for which application for sanction to a loan of £4,500 had been made would not be required, it has been resolved to withdraw the application in respect of the feeder referred to, and to reduce the amount applied for by £2,650.

Kilmarnock.—At a meeting of the Town Council on the 20th inst. it was stated that the drawings of the tramways during the first year amounted to £8,543, while the working costs were £6,200, and, after allowing £2,300 for interest on capital and expenses of the opposition to the order, the net profit was £42. A motion to insert a clause for payment of trade union wages in all Corporation contracts was defeated by 12 votes to 11.

E.P.S. Batteries.—The Electrical Power Storage Co., 4, Great Winchester-street, London, E.C., have issued their usual most useful and ornamental diary, blotting pad, and calendar. We notice two inserts drawing especial attention to the company's laboratory batteries for demonstration and lecture purposes, students' practical use, testing, and miners' electric safety lamps, hand lamps, etc. The company's prices for complete cells, renewals, and plates have recently gone up 5 per cent.

Paddington.—At their last meeting the Borough Council adopted a minute of the Finance Committee recommending that the attention of the London County Council should be directed to the recent quinquennial assessments of the municipal electric undertakings of Bermondsey, Fulham, Hackney, Hammersmith, Hampstead, Islington, Poplar, St. Pancras, Shoreditch, Stepney, and Woolwich. It was suggested that the assessments should be raised to the real values of the undertakings.

Edinburgh.—The Town Council have decided to appoint a Tramway Committee, consisting of 16 members, as one of the standing committees, and ordered that all remits on the subject of the tramways should be transferred to this committee. In addition to the Lord Provost, the following councillors have been appointed: Messrs. A. A. Murray, Bailie M'Michael, Currie, Bailie Dobie, Grieve, Mallinson Treasurer Brown, Neil M'Leod, Bailie Clark, Dean of Guild Wilson, Chisholm, Cunningham, Macpherson, John Murray, and Smith-Elliot.

Calcutta.—The policy of the Corporation in requiring the tramway company to contribute freely to the widening and improvements of such roads as happen to need rectification for their lines appears to be a wise one, for, after all, the tramway extensions only run in sure directions and only follow the most remunerative routes which will plentifully and increasingly recoup any outlay incurred in making them. It is, therefore, only reasonable for the Corporation to insist on the tramway company carrying out in such cases the necessary road improvements.

Erith.—The Electric Light and Tramways Committee of the Borough Council recommend that the rate of pay of conductors be increased from 5½d. to 6d. per hour, as from Dec. 31. With reference to the proposal that the London County Council should construct the authorised tramways from Abbey Wood to the existing Bexley lines in High-street, Plumstead, it was stated that the Highways Committee of the County Council were giving careful consideration to the suggestion, and a communication would be sent so soon as a definite decision had been arrived at.

Great Yarmouth.—An arc lamp which consists of a pair of 23-c.p. lamps with reflectors, placed back to back, has been adopted as the most suitable type to give the best results. Fifty lamps at £3. 3s. are to be placed on short posts, and the lamps are to have a reflector placed over the top. The General Purposes Committee have asked the Electricity Committee to give instructions so that the alternate arc lamps in the borough may be kept lighted until half-past six in the morning from the end of October until the end of January without extra cost to the former committee.

North London Tramways.—Colonel Yorke, on behalf of the Board of Trade, on the 20th inst. inspected the length of tramway which has been constructed from the Highgate Archway to the Archway Tavern to link up the tramway systems of the Middlesex and London County Councils. This short length of tramway has been constructed by the London County Council on the overhead electric system, but, until their own tramways have been electrified, will be leased to the Metropolitan Electric Tramways Limited, and will be worked by them in continuation of the line from Whetstone to the Archway which they already lease from the Middlesex County Council.

Ayr.—The County of Ayr Road Board have recommended the County Council to petition against the order to construct the tramways between Stevenston and West Kilbride, *via* Saltcoats and Ardrossan, unless and until a satisfactory agreement with the promoters had been adjusted. It was pointed out at the last meeting of the committee that several parts of the road were too narrow to admit of a tramway line. At some parts the actual roadway was as narrow as 15ft. The promoters proposed to put down the line on the north side of the road, but the committee were of opinion that the line should be put in the middle of the road, and that the road should be not less than 22ft. between kerbs.

Tramway Men's Loan Clubs.—Two cases are reported in which drivers and conductors employed by the London United Tramways Co. who belong to loan clubs were this Christmas unable to participate in the annual "share out" owing to the disappearance of the men entrusted with the funds. In one instance, so far as can be estimated, between £450 and £500 is missing, together with the treasurer. In the second case the members had anticipated a distribution of some £200. Both the money and the man who had it in his keeping are missing. The clubs are purely private enterprises, promoted entirely by the employés at the depôts, and in no way is the London United Tramways Co. responsible.

Cardiff.—Mr. Arthur Ellis, electrical engineer and manager for the city, on Friday asked the Finance Committee that in the electric lighting department actual and not estimated profits should be dealt with. He said that the Electric Lighting Committee estimated that the profits of the year would amount to £5 000, and the Finance Committee allocated £3,000 towards the relief of rates. The electric lighting profits only amounted to something over £2 000, with the result that the city treasurer's accounts showed that there had been a loss on the working of the department. What he suggested was that for one year nothing should be allocated from estimated profits towards the reduction of rates, and that subsequently the actual profits should be dealt with. The committee agreed to the suggestion.

Accident.—The *Glasgow Evening News* contains the following account of an accident which occurred on the 27th inst. Alexander Melville, an electrical engineer in the employment of the British Westinghouse Co., 65, West Regent-street met with a terrible death this morning at the new sub station in Stirling-road, in connection with the Corporation electricity department. Along with a man named William Scott, Melville was at work on the platform from which the high-tension switches are controlled, conveying a current of 6,500 volts. Evidently under the impression that the current was off, Melville got hold of one of the switches, and the electricity passed through his body, killing him instantaneously. When the current was turned off, which was done in a few seconds, the body dropped to the floor. Dr. Duff was called in, and he pronounced life extinct.

Private Bills.—The London and North-Western Railway Co. has inserted in its omnibus Bill for next session powers to create £500,000 additional capital, and further borrowing powers to the extent of £150,000. The new capital will provide mainly for the construction of over 21 miles of new railways, of which over 14 miles will be laid down in South Wales and nearly six miles in the construction of a railway from Shepshed to form a junction with the Great Central Railway at Loughborough.

Delagoa Bay.—Speaking at the annual meeting of the Delagoa Bay Development Corporation, Mr. J. C. A. Henderson, the chairman, alluded to the electric tramways, which, he observed, were at present the least satisfactory of the corporation's undertakings. The freight car traffic was a prominent feature. He informed the shareholders that Messrs. Mordey and Dawbarn, of Westminster, had been consulted with reference to the working of the tramways, and a scheme was under consideration which would produce, he hoped, better results.

Birkenhead.—The Corporation have decided to apply for an injunction to restrain the railway company from running their motor-omnibuses. The Corporation are acting on counsel's opinion, which is that the company have no powers authorising them to run such a service. Grounds put forward by the Corporation are that the motor-omnibuses will involve extra expense to the rates, for maintenance of roads and other purposes, amounting to £11,000 a year, equal to a rate of nearly 6d. in the pound, and that the value of property in the better-class residential districts traversed by the vehicles will be reduced.

Bury.—The annual report of the Bury Corporation tramways states that the total revenue was £19,544, and the working expenses £11,041. After paying interest on capital and repayment of sinking fund, there is a net balance of £510, which has been carried to reserve fund. The number of passengers carried was 4,065,455. The average revenue per car mile was 9·21d., and the average working expenses per car mile, including power cost, was 5·20d. Since the complete system had been working the average number of passengers carried per week had been 96,448, and an average of 8,805 workpeople per week had been carried at half-fare.

Wash-outs—Insignificant damage—elaborated and magnified by the daily Press, hard up for copy during the holidays—was done to the basement of the Charing Cross and West-end Electrical Supply Co. by the bursting of a water-main near St. Martin's-lane on Boxing Day. A similar incident occurred in Arthur-street in the City on Christmas Day. There a distribution area was cut off for about 20 minutes; at the first-named place no inconvenience was caused at all. We only mention the matter because of the exaggerations complained of, and also because there was a similar case in the West-end some time ago, and which is at present *sub judice* but which we are informed will probably be amicably settled between the parties when the case is called in March next.

Dundee.—The *Dundee Advertiser* publishes in full the correspondence which took place between the Corporation and Messrs. Gourlay Bros. and Co. *re* the supply of electrical current to Camperdown Shipyard. In their last letter Messrs. Gourlay wrote to the Dundee town clerk, under the date of Dec. 11, 1905: "That owing to the Electrical Committee's refusal to supply us with continuous current as arranged, and also seeing that they now propose to supply three-phase current, which is not so suitable for our purposes, and seeing that we have been quite unable to ascertain any date upon which either current would be available, we are obliged to abandon the scheme to take the Corporation current, and have, therefore, to-day entered into a contract whereby we shall generate our own current."

Vienna Telephones—The *Daily Telegraph* Vienna correspondent says: "Telephonic communication with Pesth, which was lately extended to Belgrade and Sofia, has also been opened up with Bucharest. At present Vienna is in touch with Berlin on the north, and with Pesth, through which it can also reach the capitals of Bulgaria, Servia, and Roumania with powerful transmitters. The rate from Pesth to Bucharest is fixed at 2s. 6d. for three minutes, or 5s. for urgent use. Up to the present the interurban telephone is not much used by the general public, but is largely patronised by the Press and by operators on the Bourse. It was probably the telephone which permitted the Vienna papers to give the recent debates of the German Reichstag at Berlin at a length of seven and eight columns the next morning."

Barnstaple.—An inquiry has been held into an application of the Town Council for sanction to borrow £4,000 for purposes of electric lighting. Mr. J. Jordan, borough accountant, stated that the number of consumers was now 256, and they started with 98 three years ago. The capital expenditure was £29,783. The revenue for the year was £3,085, and the expenditure on the revenue account, including interest and redemption debt, £3,110. He said that no surplus was shown, because the Christmas accounts, which amounted to £514, were not included. Mr. C. E. R. Chanter opposed the application as a large ratepayer and an owner of property, but Mr. Bosson, the town clerk, submitted that Mr. Chanter appeared in no other capacity than as vice-chairman of the gas company, and was assisted by the secretary of the company (Mr. Schofield).

Dewsbury.—It seems as though the projected tramway from Dewsbury to Earlsheaton and Ossett will be taken in hand at an early date. The Dewsbury Town Council have passed a resolution in favour of applying to the Board of Trade for a provisional order for the purpose of reviving and extending the time for the exercise of the powers of the Dewsbury Corporation Tramways Order, 1904. Negotiations have been proceeding between the local authorities and the Wakefield and District Light Railway Co., and it is hoped the company may be induced to undertake the construction and working of the line. The Ossett Town Council have also passed a formal resolution to extend the time for carrying out the construction of an electric tramway from Ossett Market-place to the borough boundary—part of the proposed scheme of tramways from Ossett to Dewsbury.

Bo'ness.—We have previously referred to the differences between the Town Council and the National Electric Construction Co. with reference to the interpretation of certain clauses of the working agreement for the electric lighting of the borough. The chief subject under dispute referred to the right of the Town Council to appoint an independent inspecting engineer to examine the plant and system, and charge the company all expenses incurred in so doing. The Town Council have now accepted an offer of the company to pay at the end of five years a lump sum of 40 guineas towards the fee of an engineer making the inspection. The Council have also resolved to accept a tender of £100 towards the payment of interest on a balance of £5,000 lying at the credit of the Town Council pending the receipt of a certificate from the consulting engineers in London before paying the Construction Co. the final instalment.

Lancaster.—The Electricity Committee have decided to supply current to the L. and N.W. Railway works at the rate of 1½d. per unit net, subject to their guaranteeing a minimum consumption of 42,000 units per annum for a period of seven years. This will amount to £262. 10s. per year, a sum which would cover the repayment on the cost of the main (£860) and the increased cost at the works, and leave a small balance of profit. The matter has not yet been confirmed by the Town Council. Amongst other things under consideration is the purchase of the following plant, estimated to cost £280. 5s.: one large wheel lathe, with motor complete, £237. 10s.; one armature cradle (the one in use being inadequate for present requirements), £24; one tyre furnace (for removing and replacing steel tyres and wheel centres) £4. 15s.; one jib crane (for handling axles and wheels when shrinking tyres on centres), £14.

Faraday House Testing Fees.—We have received from the Electrical Standardising, Testing, and Training Institution a pamphlet describing the facilities for testing at Faraday House, together with a list of charges. The scope of the institution's work embraces everything that is supplied by the electrical and associated industries, and the scale of fees is very reasonable. The institution is prepared to test complete sets of tramway insulation, fees for which will be quoted on application. For testing the resistance of rail bonds the fees range from one guinea, and for electrical and mechanical tests of globe strain insulators the fees are 31s. 6d. The laboratories and workshops at Faraday House are provided with instruments and apparatus requisite for this class of work, and are connected with the public electricity supply mains, from which a constant supply of both direct and alternating current is always available.

Paris.—All the navvies who were on strike have now returned to work on the Metropolitan Underground Railway, but the masons and tube-layers are still out. The navvies have not obtained all their demands from the contractors and engineer, but they are now manifestly satisfied with the agreement proposed, although they refused it on Nov. 30, after they had been a week out. Under this agreement piece-work is abolished, extra pay is given for working in water, and no fines will be imposed. In the meantime, the inquiry ordered by the Municipal Council as to the manner in which the contractors and engineers of the underground line are conducting and completing the works is continuing. The members of the Municipal Council who are engaged on the investigation are accompanied by workmen, who point out the deficiencies in the construction of the line under the Place de la République and elsewhere.

London Gazette—The Electrical Ore-Finding Co. has been wound up voluntarily, and Mr. J. D. A. Norris, Suffolk House, Laurence Pountney-hill, London, appointed liquidator. The first meeting in the estate of W. Leslie, lately carrying on business as an electrical engineer at 22, Bangleore-road, Putney, will be held at 132, York-road, Westminster Bridge, S.E., at 12.30 p.m. on Jan. 2. The Atmospheric Electrical Purification Co. has been wound up voluntarily, and Mr. E. E. Groome, 21 Spring-gardens, Manchester, appointed liquidator. The Shanghai Electric Tramways Co. has been wound up voluntarily, and Mr. G. G. Walker, 19, St. Swithin's lane, London, E.C., appointed liquidator. The St. Helens Cable Co. has been wound up voluntarily, and Mr. A. Wenham, 10, Walbrook, London, appointed liquidator. The discharge of A. E. Brooks, electrical engineer, 110, Cheapside, London, has been suspended for two years.

London County Council.—A trial trip on the first underground tramway constructed in London by the County Council was held in the early hours of the 22nd inst. So far the underground tramway, the authorised southern terminus of which is on the Embankment close to Waterloo Bridge, has been completed only to the crescent of Aldwych, but as the electrification of the tramway to the Angel at Islington is now complete, it was thought desirable, with a view to its anticipated opening for traffic early in the New Year, to test the working arrangements as regards of gauge, curves, gradients, continuity of current, and other matters. A single-decked inspection car bearing the number 101 ran smoothly along the tunnel, and with ease it climbed the steep ascent up to Theobalds road, and on emerging was shunted by a pointsman in readiness on to the down line, and the descent was made with equal smoothness. Through runs to the Angel and back followed with satisfactory results.

Littleborough.—The Electricity Committee have now been empowered to take such steps and obtain such expert assistance as they deem necessary in order to submit a complete electric lighting scheme, with estimate of the cost, to the Council at a future meeting. The approximate cost is stated at £2,000. This means an annual expenditure on interest and depreciation at 6 per cent. of £120. The Central school uses 2,655 units per annum, the Council offices 613, fire station 93, stables 84, textile school 617, and free library 1,174. By obtaining current from the Rochdale Corporation at about 2d. per unit, and with the sum of £120 for interest and repayment, there will

Digitized by Google

be a total annual expenditure of £155. 7s. It is considered that a reduction to a reasonable sum of the price of current to the Central school would mean, at 4d. per unit, an income of £42. 6s. Compared with the present cost, the Council will be able to save 2d. per unit on the remaining 2,000 units, which would amount to £16. The scheme would, therefore, mean an expenditure of only £97 per annum, and some revenue which may be expected from private lighting.

Twickenham and Teddington Electric Supply Co.—The company's new Bill contains provisions as to exercise by Twickenham and Teddington Electric Supply Co. or Edmundson's Electricity Corporation of powers of and exemption of Hampton Urban District Council and Teddington Urban District Council from liabilities under Hampton Electric Lighting Order, 1901, and Teddington Electric Lighting Order, 1901; power to make agreements for such purposes, and confirmation of existing agreements; provisions as to transfer of such orders; further powers with respect to supply of electrical energy, laying of electric lines, etc., and breaking up streets, railways, etc., within Twickenham, Hampton, Teddington, Hampton Wick, Sunbury, Feltham, Hanworth, Ashford, Shepperton, Ham, East and West Molesey, and Esher and the Dittons, and powers to supply in adjoining areas; agreements with and powers to electric undertakers and others in such adjoining areas; confirmation of and powers to maintain existing works, etc.; terms and conditions of supply; provisions as to purchase by local authorities; incorporation and amendment of Acts and orders, etc.

Rochdale-Heywood. — The length of tramway between the Rochdale boundary and the Heywood Market-place was inspected by Colonel Druitt (on behalf of the Board of Trade) on the 20th inst., who sanctioned its immediate use for traffic. A satisfactory agreement was come to between the Rochdale and Heywood representatives on certain points in the draft agreement for the working of the new lines. The terms of the settlement provide that Heywood shall supply current and keep the track and overhead equipment in order, and that Rochdale shall supply cars and work the lines. The through fare from the Rochdale centre to the Heywood Market-place is 3d., and Heywood's share of this is to be calculated on the basis of car mileage, giving Heywood 1·17d. and Rochdale 1·83d. To the Rochdale borough boundary at Heywood Cemetery the distance is 2·16 miles, and the fare so far has been 2½. From Heywood Cemetery to the Heywood Market-place the distance is 1·37 miles, making a total distance of 3½ miles from the Rochdale centre. The only point that has been left over for settlement by the respective sub-committees is the question of the overlapping stages and the basis on which receipts taken on these shall be divided. An agreement will now be drawn up in accordance with the draft signed last week.

Nottingham.—The town clerk has prepared for the City Council a report on the proposal to amend the Notts and Derbyshire Tramways Act, 1903, the Bill for which will be promoted in the next session of Parliament. The principal clauses that may affect the Corporation deal with extensions of the time for purchasing land and for the construction of the tramways until Aug. 11, 1908, and the Corporation's power of purchase, which is now put at 21 years, or at the expiration of the lease. By Section 11 of the Bill power is given to the company to run motorcars, omnibuses, or other vehicles in connection with or in extension of their tramway system. By Section 34 of the Bill power is given to the promoters to sell to the Corporation: (1) the tramway commencing at the present system in the Gregory-boulevard and going along Abbey-street, Dunkirk-road, Beeston-road to the city boundary; (2) the tramway commencing at the present system in Bentinck-road and going along Alfreton-road and Nuthall-road to the city boundary; (3) the tramway commencing in Sneinton Market and going along Carlton-road to the city boundary; (4) the tramway commencing at the termination of the present system on the Mansfield-road at Winchester-street and going along the Mansfield-road to the city boundary. The remainder of the sections in the deposited Bill do not affect the Corporation.

Harrow.—At the last Urban District Council meeting the surveyor presented a special report on the proposal of Northwood to apply to the Board of Trade for an order to supply electricity for lighting and power in the district. The application embraced power to cut, stop up, and divert roads in the district, and he suggested that the application be opposed with a view to the insertion of protective clauses. Clauses would have to be inserted for the protection of the sewers, the price to be charged restricted, and the power obtained to limit the period of the order. At present power was taken for 42 years, and not until the expiration of that time could the Council purchase, even if they wished to do so. Mr. Hogg thought there should be a clause prohibiting the opening of a number of roads at the same time. The report was adopted, the clerk and surveyor being instructed to make all necessary preparation for opposing. The surveyor also presented a report on the proposal of the North Metropolitan Electric Power Co. to obtain powers to extend their mains from Edgware Bridge to Stanmore corner. He pointed out that the company did not propose to light Little Stanmore. They undertook to carry out the work within two years, and to supply electricity for private as well as public purposes. The power sought by this company would preclude the Council from executing any work of a similar character, and he suggested that the usual steps be taken for insuring protective clauses. The Council agreed.

Islington.—After a long debate on the report of the Lighting Committee, which appeared in our last issue, the matter has been deferred to two committees for further report. The report referred to in our issue of Dec. 15 with regard to the extension of arc lighting came again before the Council last Friday, and was referred to the Finance and Lighting Committees. The report stated that in the interests of the borough and also of the electric light undertaking, it was desirable that there should be a considerable extension of street arc lighting, and they proposed to extend the supply to about 15 miles of streets at present lit by 714 incandescent gas lamps. These they proposed to supersede by 245 electric arc lamps. If their suggestion were adopted, they proposed that the sum of £15,734 allocated to the electric lighting department for street-lighting last year should not be increased but remain a fixed charge, and in that event the cost per unit would be nominally reduced from 3½d. to 2½d., and the cost per lamp per annum, exclusive of carbons and trimming, nominally reduced from £32. 2s. to £20 12s. A statement had been prepared by the electrical engineer, from which it appeared that the present sum paid under contract to the gas company for gas would be more than enough to pay the interest on the loan, together with the cost of maintenance and charges for carbons. The electrical engineer's estimate of the amount required to carry out the complete scheme was £21,011, of which £3,812 had already been sanctioned by the London County Council, leaving an amount of approximately £17,000 to be raised by loan in the usual manner. The committee recommended that the estimate be approved, and that the Lighting Committee be authorised to proceed with the scheme, application being made to the London County Council for sanction to the borrowing of £17,200.

Heckmondwike.—Mr. G. H. Carter, the District Council's electrical engineer, in his report on the working of the station in Bath-road for the six months ended Sept. 30 last, gives the following figures: Units generated — traction, September, 1905, 130,453 (September, 1904, 124,305); lighting, 160,915 (68,742) — total, 291,368 (193,047). Units sold—traction, 118,548 (117,482); private, 20,515 (15,090); power, 81,047 (12,645); street-lighting, 17,327 (13,814)—total sold, 237,437 (159,031). Consumers connected, 18 (14); equivalent 8-c.p. lamps, 2,685 (1,626); number of consumers, 197 (149); total lamps connected, 22,823 (13,326). The cost of generation and distribution over the same periods per unit sold were: coal, ·31d. (·33d.); oil, waste, and water, ·05d. (·04d.); wages, ·23d. (·26d.); repairs, ·10d. (·03d.); management, insurance, rent, rates, and general charges, ·30d. (·34d.); cost per unit sold, 1·01d. (1·03d). The financial results of the six months' working are as follows: Expenditure—fuel, 1905, £311. 11s. 2½d. (1904, £221. 18s. 3d.); wages, £231. 13s. 10d. (£177. 5s. 10½d.); oil, water, and stores, £55. 8s. 3d. (£39. 13s. 2d.); repairs, £101. 1s. 4½d. (£25. 5s. 0½d.); works costs, £699. 14s. 8d. (£454. 2s. 4d.); management, £171. 13s. 10½d. (£138. 14s. 2d.); general charges, £23. 10s. 3½d. (£20. 4s. 6d.); insurances, £8. 5s. 9d. (£4. 2s. 3d.); rent and rates, £97. 2s. 6d. (£67. 3s. 4d.)—total costs, £1,005. 7s. 1d. (£684. 6s. 7d.). Income—Sale of energy: private, £313. 9s. 7d. (£209. 14s. 3d.); power, £340. 4s. 7d. (£59. 7s. 7d.); street-lighting, £204. 16s. 6d. (£214. 1s. 6d.); traction company, £972. 15s. 7d. (£865. 3s.); meter rents, £15. 2s. 1d. (£10. 19s. 1d.); baths, £12. 10s. (£12. 10s.)—£1,858. 18s. 4d. (£1,372. 15s. 5d.); costs as above, £1,005. 7s. 1d. (£684. 6s. 7d.)—balance, £853. 11s. 3d. (£688. 8s. 10d.); six months' interest and sinking fund on £20,843 at 6½ per cent., £677. 7s. 6d. (£677. 7s. 6d.)—£176. 3s. (£11. 1s. 4d.).

PROVISIONAL PATENTS, 1905

DEC. 15.

26097. An apparatus for centralised control of electric switches connected to alternating-current distributing networks. Joseph Duncan Spark, 3, Fairholm-road, West Croydon.

26109. Improvements in and relating to conductors for the electric lighting of miners' safety lamps. Didymus Thomas and William Phillips, Bryn Awel House, Treharris, Glamorgan.

26122. Improvements in and relating to incandescent and other electric lamps. William John Fowler, 3, Lincoln's-villas, Highwood-hill, London.

26144. Improvements in and connected with fuses for electrical circuits. Walter Edward Richards, 16, Great George-street, Westminster, London. (Complete specification.)

26149. An improved system of electrical distribution. Roderick McKenzie Palmer, 11, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Dec. 22, 1904, being date of application in United States.) (Complete specification.)

26162. Improvements in couplings for electrical wires. Henry Fairbrother, 33, Cannon-street, London. (John Griffith Thomas, U.S.A.)

26182. Intercommunication by means of telephones or other electric signalling apparatus over lines used as feeder cables, pilot wires, or the like. Reginald William Klitz, 15, Herbert-road, Wimbledon, London.

26187. Improvements in means for controlling the lights in railway carriages lighted by electricity or gas. J. Stone and Co., Limited, and Alfred Henry Darker, 77, Chancery-lane, London.

DEC. 16.

26207. Improvements in protective devices for use in the distribution of electricity by overhead wires for electric tramways and the like. James Robson, 3, Devonshire-place, Selly Park, Worcestershire.

26219. A spring improved raising and lowering electric light device. Walter Verum, The Dendles, Latham-road, Twickenham, Middlesex.

26223. Improvements in or connected with electric tramways on the conduit system. Henry James Peddie, 14, Fountainhall-road, Edinburgh.

Digitized by Google

26281. Improvements in electromagnets for alternating-current circuit breakers and the like. Michael Birt Field and Ferranti Limited, 18, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED

To be published Jan. 4.

1905.

5980. Alternating-current dynamo-electric machines. British Thomson-Houston Company, Limited. (General Electric Company.)

10794. Electrical signalling apparatus particularly adapted for signalling in mines. Woodworth.

14441. Means for suspending and sustaining electric lamps at any desired height. Whitaker and Wass. (Date applied for under International Convention, July 14, 1904.)

15289. Telephone call registers. Meyer.

15594. Conveying currents to electrodes arranged in electrically insulated tubes. Garz und Co. Energieverei und Maschinen Fabriks Act.-Ges. (Date applied for under International Convention, Aug. 26 1904.)

17181. Thermo-electric couples. British Thomson-Houston Company, Limited. (General Electric Company.)

19138. Dynamo-electric machines. Allgemeine Elektricitäts Ges. (Date applied for under International Convention, Sept. 22, 1904.)

19201. Constant-current electric distributing system for the utilisation of variable sources of power. Böhm.

19752. Road vehicles. British Thomson-Houston Company, Limited. (Allgemeine Elektricitäts-Ges.)

Supplement to "The Electrical Engineer,"

JULY 7, 1905.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

794. Describe the method of arranging the stator windings of two or three phase motors with a view to speed regulation. Is it possible to arrange a 12-pole winding so as to reduce to eight poles?—OMEGA.

ANSWERS.

Question No. 786.—At a hydro-electric installation some surplus power is available. State the best method of obtaining a record of the same with a view to installing another turbine 12 months hence. Fall, 11ft., subject to frequent floods.

Answer to No. 786 (*awarded* 5*s.*).—It is evident from the question that only an approximate record of the surplus horse-power available is required, say to within 5 or 10 per cent., on account of the very varying nature of the conditions under which the water is supplied and fed to the installation. It would, however, be a very wise plan, indeed, if two sets of records were taken—one when the fall of the water *is* subject to the flood, and the other when it *is not*. In the very nature of things the two records would be entirely different. In order to obtain a record or records, certain data are required. In the first place, we require to know the quantity of water which is passing over the weir—presuming the existence of such—during unit time, say one minute, when the fall is working under either normal or abnormal conditions according to the record which is required. If the velocity of the water and the depth of the water passing over the crest of the weir can be observed or computed, then the quantity of water passing over the weir can readily be calculated. The velocity of the water may be made in various ways. The simplest, and certainly the least expensive way, is to observe the velocity of some floating body in the middle of stream (as, for example, a moderately-sized piece of wood or other similar body). Let this velocity be denoted by V, then the approximate mean velocity, v, is equal to

$$\frac{7{\cdot}7 + V}{\frac{10{\cdot}3}{V} + 1}.$$

Having found the above quantities, we can then calculate the weight of water passing over the fall per second.

Let W = weight of water, in pounds, passing per second;
v = velocity of water per second;
d = depth of water over crest of weir in feet;
b = breadth of weir in feet.

Then $W = 62{\cdot}3\ b\ d\ v\ c$, where c = coefficient of discharge of the water passing over the weir, and may be taken to have the average value of ·64.

$$\therefore\ W = 40{\cdot}9\ b\ d\ v.$$

The horse-power of the fall

$$= \frac{(40{\cdot}9\ b\ d\ v)\ (60 \times 11)}{33{,}000} = 8{\cdot}2\ b\ d\ v.$$

Subtracting from this the horse-power of the turbines already at work in the station, we get as a result the horse-power available for utilisation in connection with the proposed turbine. It would be well, however, not to depend to any appreciable extent upon the result thus obtained, but to take about 80 per cent. of it as the *actual* horse-power available at the turbine. This takes into account losses neglected in obtaining the first result.

From the wording of the question it is assumed that some permanent record of the available horse-power is required. If such is the case, then the above data should be obtained, and the above computation made every week or every month—according to circumstances and facilities—between the present time and 12 months hence, when the projected scheme will be carried out. The results can then very conveniently be plotted on a sheet of squared paper, the abscissæ representing time and the ordinates power. By this means a permanent and direct record can be obtained, and at a glance the average state of things can be seen. This will help the querist considerably in drawing up specifications as regards the power of the turbine.—G. W. BURLEY.

Question No. 787.—Has Reuleaux's diagram been adapted to the analysis of the Corliss valve motion? If it has, explain the method and show how by its use problems relating to a double eccentric gear may be solved.

Best Answer to No. 785 (*awarded* 10*s.*).—The Reuleaux diagram can, to a certain extent, be applied to some forms of Corliss valve gear, but in so doing it loses its principal recommendation of simplicity. Modern Corliss gears are generally of the double eccentric variety, and this will be the only type considered. Fig. 1 shows diagrammatically

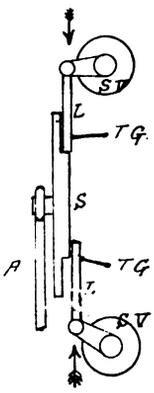

FIG. 1.

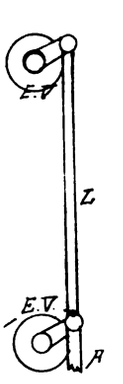

FIG. 2.

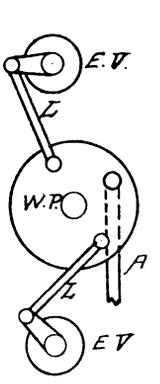

FIG. 3.

FIGS. 1, 2, AND 3.—A, Driving Link; S, Slider; L, Link-Operating Valve Lever; S V, Steam Valve; E V, Exhaust Valve; T G, Tripping Gear; W P, Wrist Plate. The arrows indicate the direction of the dash-pot action in Fig. 1.

a type of steam admission gear which, in principle at least, is fairly common. Figs. 2 and 3 represent two of the more usual forms of exhaust-valve motion. Considering the steam admission valve, the most radical departure from the ordinary Reuleaux diagram occurs in the travel of the slider. To enable the catch gear to engage without a violent jar, the throw of the eccentric is reduced to approximately half that necessary with an ordinary slide valve giving the same port opening and admitting steam during the whole of the piston stroke. This introduces what may seem an anomalous state of affairs; retaining the lead, the steam lap and the angle of advance become negative. To draw the diagram. Set out the sector W V Z (Fig. 4), representing to scale the movement of the valve lever and also that of the valve. Draw T S, representing the line of motion of the slider in its relative position. Drop perpendiculars from the arc V W to T S at the ends of the stroke of valve and also from the point

Digitized by Google

at which the valve opens. Then if C = the distance the slider must move before the valve opens, O = the port opening (referred to slider), and c = the clearance necessary to allow the trip gear to engage, then the slider

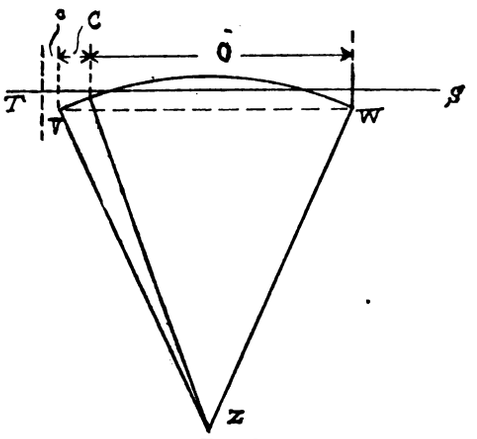

FIG. 4.

travel = O + C + c = T. Draw the circle A C B D (Fig. 5), representing to scale the travel, T, and let this also represent the crank-pin circle. Draw a diameter A B for the line of dead centres, also a diameter C D at

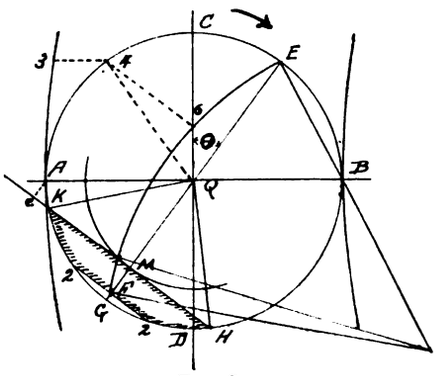

FIG. 5.

right angles. From the centre, Q, draw Q K, making A Q K = the angle of admission. From Q with radius = O − $\frac{T}{2}$—that is = the negative lap—describe an arc. From K draw K M H tangent to this arc and meeting the

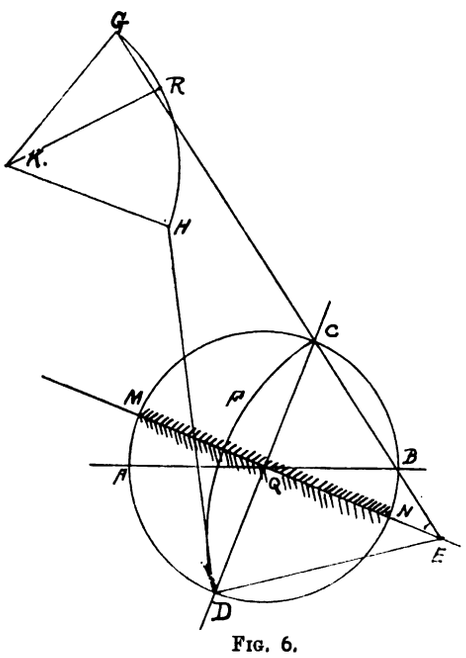

FIG. 6.

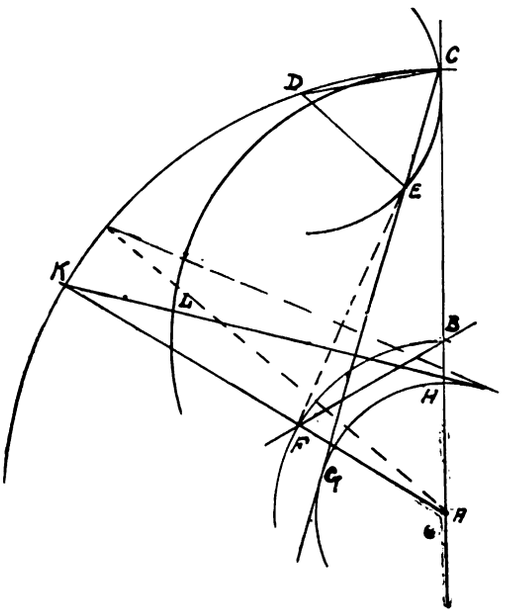
circle again at H. Draw 2 F 2 parallel to K H at a distance = C (Fig. 4). Through Q draw M Q E at right angles to K H. To E F apply a figure constructed similarly to Fig. 4. Draw the connecting-rod arcs. Then A e is the lead, Q E is the crank position for maximum port opening. H is the point at which valve would close if for any reason the trip gear did not disengage. The arc 2 G 2 represents the period allowed the trip gear in which to engage, and C Q E = θ = angle of advance. The port opening for any part of the piston stroke can be found as shown at 3-4 and 4-6. The only other point worthy of note is that the latest possible cut-off with the gear shown occurs at E; any attempt to carry the steam further would result in the trip gear not acting at all, and the valve would not close until H.

Of the two exhaust gears shown, that of Fig. 2 presents no difficulty, and a figure may be constructed on similar lines to Fig. 5. The wrist-plate motion (Fig. 6) introduces more complications. However, if the circle A C B D be taken to represent to different scales the crank-pin circle and the eccentric circle, the arc C F D the radii of the wrist-plate pins, and the arc G H the movement of both the valve lever and the valve, the number of lines necessary is reduced to a minimum. It is, of course, inconvenient to work to so many different scales, but if convenient scales are selected for the crank-pin circle and the valve movement, the others will not cause much trouble. The opening and closing of the valve is represented on the lower part of the figure by the line M N and on the valve arc by R. There should be no difficulty in setting out diagrams for Corliss gear. The points of opening and closing, of maximum opening, etc., follow the same laws as an ordinary slide valve. The only difference is in the amount, and this depends entirely on the linkwork employed.—B. O. S.

Answer to No. 787 (*awarded* 5*s.*).—There is no reason why "G. H. H." should not use the Rouleaux diagram for solving problems involving Corliss valve gear. The valves being separately adjustable, it is advisable to keep the diagram of each valve independent of the others. The steam admission valves are generally worked by a trip motion with a variable cut-off. This diagram should give no difficulty, the only points of importance being the lead and the point of maximum port opening which regulates



the latest point of cut-off permissible. Taking the exhaust valves, to the type in which valves for each end are connected by a straight link, the Rouleaux diagram can be applied in the ordinary way. The case in which the valves are worked by a wrist-plate involves more work, but presents no difficulty, if Muller's circles be applied as adapted for a case in which the axial line of the cylinder does not meet that of the crankshaft. Set out the valve motion to scale, as shown at A B F and C D E. Draw the Muller circles for a crank, A B, and connecting rod, B C. Join C E and produce it past A. Draw an arc, G H, tangent to C E produced. Produce A F to meet the outer circle at K. Then the distance, K L, measured on a line tangent to the arc, G H, will give the valve movement within a close degree of accuracy. In the same way the position of the valve for any position of the wrist-plate may be found.

Digitized by Google

The ordinary Reuleaux diagram can be then applied to the line F B, making F and B the points of extreme motion of the valve, and working from them.—N. C. T.

Question No. 788.—A three-phase 3-h.p. induction motor with squirrel-cage rotor takes 20 amperes at starting on no load. When the speed has got up to normal the current is two amperes. With the idea of decreasing starting current, a choker is connected in circuit. This choker consists of three separate superimposed windings, one in each phase. On again starting motor, the initial current is now 14 amperes, and running current scarcely readable. What is the reason for this apparent increase of power factor?

Best Answer to No. 788 (*awarded* 10*s.*).—It is evident that the presence of the choker has a considerable influence on the E.M.F. available at the motor terminals, and, therefore, that the choker absorbs a considerable portion of the E.M.F. in each phase. Now, the sum of the currents in all the mains of a monophase, two-phase, or polyphase supply must be zero—that is to say, at any particular instant the sum of all the currents in one direction must be exactly equal to the sum of all the currents in the reverse direction, and, therefore, since the three windings of the choker are superposed, and one winding is in each of the three phases, no choking action will result if all the coils are wound in the same sense. There is, however, evidently a considerable choking effect, for it is out of the question to suppose that the reduction of potential is due to ohmic drop, and, therefore, we must conclude that the three coils are not all connected in the same sense, but that one of them is reversed. The result of this is easily seen on reference to the vector diagrams (Figs. 1 and 2). The vectors

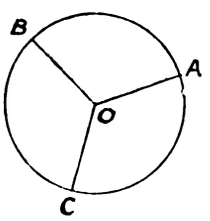


FIG. 1.

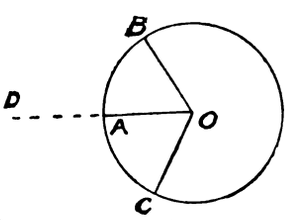

FIG. 2.

O A, O B, and O C represent the three currents. In Fig. 1 the sum of the three is zero, whereas in Fig. 2, in which O A has been reversed, the sum of the three vectors is the vector O D, which is in phase with O A, but twice as great. Since there is under these conditions a resultant current in the choker, there will be developed there a back E.M.F. or choking action, but this E.M.F. will be equal in all three windings at any instant, as they are superposed; therefore, if in Fig. 3 the triangle A B C is the

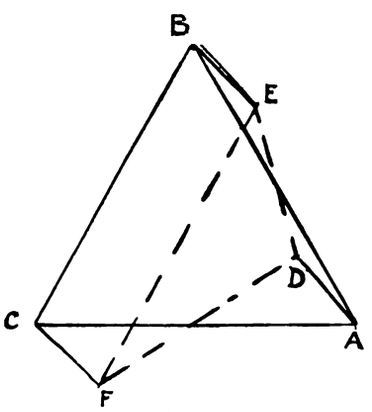

FIG. 3

vector diagram for the voltage existing between the mains before the choker is reached, the voltage after the choker may be represented by the vectors forming the three sides of the triangle D E F, where A D, B E, and C F are all equal and in phase, and represent the induced E.M.F.'s in the choker, the vector A D being in the reverse direction to the other two, on account of the winding in that main being reversed. It will be seen that not only is the voltage reduced by the choker, but that the system is no longer symmetrical, for if the original voltage vectors formed an equilateral triangle, the second triangle cannot possibly be equilateral. It is possible that the ammeter on which the current for the motor was observed was connected in the main in which the current was most reduced, for, of course, the currents in the mains will no longer be equal if equal before; but quite apart from this one would expect the no-load current of an induction motor to be reduced by a reduction of the applied voltage, as will be seen from the following reasoning:

The torque in an induction motor is proportional to the product of the magnetic flux, the induced current in the rotor, and the cosine of the angle of phase displacement between them. Now, the induced E.M.F. in the rotor $\propto$ flux $\times$ slip and the induced current

$$= \frac{\text{induced E.M.F.}}{\sqrt{R^2 + p^2 L^2}},$$

where R is the resistance of the rotor windings; L is the induction of the rotor; and p is a constant depending upon the slip. Therefore

$$\text{the induced current} \propto \frac{\text{flux} \times p}{\sqrt{R^2 \times p^2 L^2}},$$

and the cosine of the angle of lag between the induced current and the flux which induces it is given by the expression

$$\frac{R}{\sqrt{R^2 + p^2 L^2}}.$$

$$\text{Hence the torque} \propto \frac{\text{flux}^2 \times p \times R}{R^2 + p^2 L^2}.$$

Now the torque required to drive the unloaded motor will be practically a constant quantity. Therefore

$$\text{Flux}^2 \propto \frac{R}{p} + p\frac{L}{R}$$

and we see, therefore, that there is one particular value of the slip for which the flux is a minimum. This will be the case when $\frac{R}{p} = p\frac{L}{R}$, since R is a constant, and L is sufficiently near a constant to be considered such, especially over a small range of flux density. The fact that the flux is a minimum when $\frac{R}{p} = p\frac{L}{R}$ can be easily shown by taking a few values of p and plotting the corresponding values of the flux.

Curves showing this connection are given in Fig. 4 It will be seen that for one particular slip the flux for each torque is a minimum. Now, the flux is proportional to the impressed E.M.F. at these light loads, and although the point of minimum induced current does not coincide with

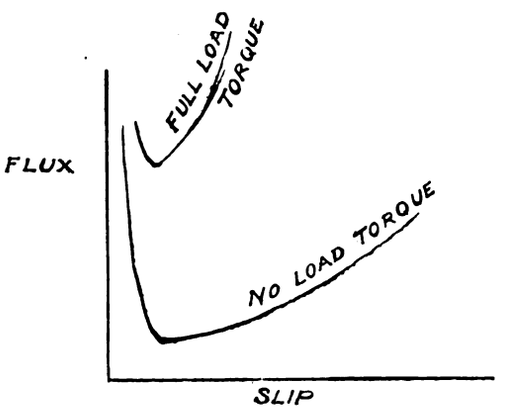

FIG. 4.

the minimum flux, because the current is also influenced by the slip, yet it is very near to it, and, obviously, if we can get both the impressed E.M.F. and the induced current down to nearly minimum values at the same time, while the power required to drive the rotor remains practically a constant, the power factor will then take on its largest value, especially as the losses in the stator will be also at a minimum, and also since the magnetising current required for the stator is least when the flux is least.

The conclusion is, therefore, that the best power factor is obtained when working with minimum flux; but, of course, the minimum flux has a different value for every torque, and for no load will be much less than for full

Digitized by Google

load, the normal voltage being arranged, of course, to suit the maximum torque.—SUPERHEAT.

Answer to No. 788 (*awarded* 7*s.* 6*d.*).—The insertion of the choking coil reduces the volts at the motor terminals below the supply volts, and this is the cause of the apparent improvement noticed. At starting, a reduced terminal voltage causes the current to fall practically proportionally (in this case from 20 amperes to 14 amperes), but, at the same time, the starting torque falls off even more rapidly than the starting current, because the torque is proportional to the product of current by useful flux in phase with the current, and the choking coil reduces both these factors. On this account, the time taken by the motor to get up to full speed from rest will be considerably greater with the choking coil in use than without it. The reduction in running current is also due to the reduced terminal voltage produced by the choking coil. This reduced voltage means a proportionately reduced flux, and therefore a proportionately reduced magnetising current and a more than proportionately reduced iron loss. Now the current taken by an ordinary induction motor when running light at full speed is the resultant of the magnetising current and the current representing the friction and iron losses, the loss current being usually almost negligible in comparison with the magnetising current. A reduction in terminal voltage consequently means an almost exactly proportionate reduction in no-load current.

Assuming that the motor has a power factor of, say, ·4 when starting—*i.e*, on short-circuit—so that the lag of the current behind the terminal volts is about 66deg, the phase relations of the current, the terminal volts, the choking-coil volts, and the supply volts may be represented

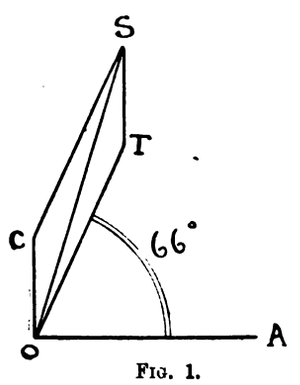

FIG. 1.

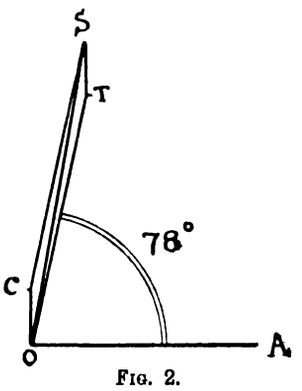

FIG. 2.

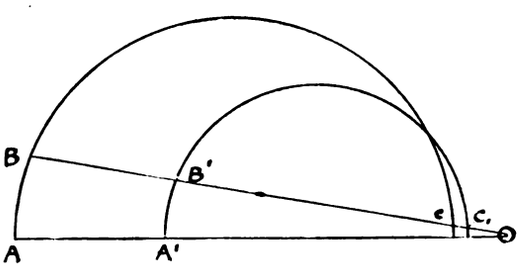
as in Fig. 1. O A represents the phase of the current, O T the terminal volts at 66deg. to O A, O C the volts over the choking coil at 90deg to O A, and of such an amount that O S, the resultant of the choking-coil volts and the terminal volts (which resultant is the total supply voltage), is equal to $\frac{20}{14}$ of O T, for the terminal volts at starting with the choking coil are only $\frac{14}{20}$ of the terminal volts before the choking coil is inserted. The value of O C to satisfy this condition scales off as about ·33 of O S. When running light at full speed the power factor of a normal motor would be about ·2, representing an angle of lag of current behind terminal voltage of about 78deg. The value of the choking-coil voltage in this case is doubtful, because if the coil has an air core or an iron core which is quite unsaturated when 14 amperes is passing, the choking-coil volts will fall in proportion to the amperes, whilst if the coil has an iron core which is highly saturated at 14 amperes, the choking coil volts might hardly fall at all when the current changes from 14 amperes to one or two amperes. Suppose that the choking-coil voltage when running at full speed falls to half the value it had at 14 amperes—*i.e*, suppose it is equal to ·165 of the supply voltage, O S. Then the diagram for full speed would be as in Fig. 2, where O A again represents the phase of the current, O T the terminal volts at 78deg to O A, O C the choking-coil volts (= ·165 O S) at right angles to O A. The resultant of O C and O T (= O S) must equal the same supply volts as O C in Fig. 1, and this corresponds to a value of O T equal to ·85 of O S—*i e*, the terminal volts when running light at full speed with the choking coil are only ·85 of the terminal volts without the choking coil. This small fall in terminal voltage would only produce an approximately proportional change in running current, and this would be hardly appreciable. If, therefore, a marked reduction in running current actually takes place when the choking coil is in use it would probably be due to the peculiar construction of the coil with superimposed windings. This arrangement would produce interactions between the windings of the different phases, which would make the three currents unequal, and a measurement of only one phase, such as was probably made in this case, would give a misleading result.—Q.

Answer to No. 788 (*awarded* 7*s.* 6*d.*).—Before this question can be answered, a clearer idea of the arrangement of the choker used in the motor circuit is needed. If the three coils, one of which we presume is placed in each leg of the system, were wound in the same direction—say, all clockwise from one end on the same core—so that each has the same magnetic circuit, as is apparently implied by the word "superimposed," the algebraic sum of the currents at any instant is known to be zero, so that the only reason for a reduction in the current at starting and running light would be due to the ohmic resistance of the "choker." But let us now assume that the arrangement of the choker is such that a true choking effect is obtained. We can easily see the reason for the reduction of the currents, and at the same time we can show that it is not due to any increase in the power factor, as "P. D." presumes.

Let $I_c = \sqrt{p^2 L_c^2 + R_c^2}$ be the impedance of the choker per circuit, where $p = 2\pi \times$ frequency, and let I_m be the corresponding value of the impedance of the motor. Then at any current C per phase we shall get a drop in voltage across the choker $= C \times I_c$. In fact, the voltage across the terminals of the motor will be reduced in the ratio $\frac{I_m}{I_m + I_c}$

From this at once follows that the back voltage to be pro-



duced by the motor is therefore reduced, so that the flux, and therefore the magnetising current, will be reduced in the same ratio. The running light current is the vector resultant of the magnetising current and the current supplying the running light losses, which latter are small in proportion to the former, so that we see that the running light current is also reduced. If we apply the Heyland diagram to the case, we see that both the starting and the running light current are reduced by the ratio $\frac{I_m}{I_m + I_c}$ given above.

In the accompanying diagrams, both of which have been drawn from the same origin, O, we have O B and O C, the starting and running light currents respectively on full voltage, while O B^1, O C^1 are the corresponding values with the choker in circuit. The power factor running light will be practically unaltered, though, of course, it will be altered slightly owing to the decreased iron losses on the reduced voltage. As regards the magnitude of the running light current, it will be seen from the diagram to be about $\frac{14}{20} = 2 \times 1{\cdot}4$ amperes. In all probability the ammeter used was not suitable for measuring small currents, in which case a current up to 1½ amperes would not be readable. If, however, "P. D." will try an instrument for lower values, he will probably find the current will be very near the figure given above.—W. J. P.

[Other replies to Question No. 788 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

QUESTIONS.

795. It is required to transmit overhead 1,000 kw. at a pressure of 50,000 volts for 40 miles. Three-phase alternating current will be used. What is the best method of calculating the sectional area of cable to use? State clearly the losses in the line, and how they are calculated.—H. G.

796. Is it necessary to clean the tubes of the superheaters of Babcock water-tube boilers? If so, what is the best method of doing so, and how long may such superheaters be run without cleaning?—PERPLEX.

ANSWERS.

Question No. 788.—A three-phase 3-h.p. induction motor with squirrel-cage rotor takes 20 amperes at starting on no load. When the speed has got up to normal the current is two amperes. With the idea of decreasing starting current, a choker is connected in circuit. This choker consists of three separate superimposed windings, one in each phase. On again starting motor, the initial current is now 14 amperes, and running current scarcely readable. What is the reason for this apparent increase of power factor?

Answer to No. 788 (*awarded* 5*s.*).—The explanation of the decrease in current readings noticed lies in the fact that, by putting the choking coil in circuit, the motor terminal voltage has been reduced, and the lower the P.D. at the terminals the less is the value of the current drawn from the mains for a given current taken by the motor, and the greater the power factor.

The most economical design for a choking coil for this purpose is such that the voltage applied to the motor at starting just overcomes the bearing friction. Suppose this value to be 33 per cent. of the line voltage and that the motor under this condition requires 2·0 times full-load current. The line current at starting = ·33 × 2·0 = ·66 full-load current. The actual value of the starting voltage can be determined in every case. Oudin, in his "Standard Polyphase Apparatus," gives the following values as representing the starting performances of modern motors when the starting voltage has the percentage values given:

Motor volts in per cent. of line volts	40	60	80	100
Line-starting current in per cent. of full-load current	112	250	450	700
Motor-starting current in per cent. of full-load current	280	420	560	700
Starting torque in per cent. of full-load torque..	32	72	128	200

Having details of line voltage and resistance of motor, and having determined by the use of non-inductive resistance the lowest permissible starting voltage, the most suitable value for the self-induction of the choking coil may be calculated. It must be remembered, however, that the value of the P.D. across the coil

$$= \sqrt{(\text{line voltage})^2 - (\text{motor voltage})^2},$$

and *not* (line voltage) − (motor voltage), for the P.D. of the choking coil is in *quadrature* with the current.—A. M. L.

Question No. 789.—How may extra high electric pressures be measured by a low-reading electrostatic voltmeter and two condensers? Express the multiplying power of the arrangement in terms of the capacities, and state the conditions necessary for its constancy.

Answer to No. 789 (*awarded* 7*s.* 6*d.*).—There are several ways of fulfilling the requirements of the above question, each of which is applicable, more or less, to any case which may arise, depending entirely upon the precise circumstances of working, so far as they include the working pressure of the system and the pressure of the voltmeter, the conditions under which the application is to be made, and the degree of accuracy which is is deemed advisable to work to. The method which is described below is *the* one which, in the opinion of the writer, is the best for extra high-tension work, because the multiplying power of the arrangement can be increased or decreased by altering the capacity of one of the condensers, and, also, a fairly high multiplying power can be obtained by the use of condensers of moderate capacities. Also, if proper care is taken in the arranging of the condensers, this method is the most accurate of all methods.

In Fig. 1 we have a diagrammatic representation of the voltmeter and condenser circuit. A and B are two mains between which the extra high potential difference is maintained; V is the low-reading electrostatic voltmeter, to which there is connected, as a shunt, a condenser, C_2. Another condenser, C_3, completes the circuit, this latter condenser being connected in series with the compound voltmeter and condenser circuit.

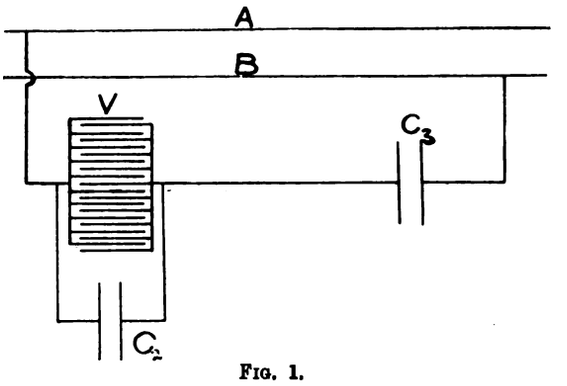

FIG. 1.

Let E = the potential difference between A and B, in all probability reaching the magnitude of 10,000 volts or more;

E_1 = the maximum potential difference that the voltmeter will indicate;

C_1 = the capacity of instrument (that is, voltmeter) in absolute units;

C_2 = the capacity of the condenser, C_2, in absolute units;

C_3 = the capacity of the condenser, C_3, in absolute units.

Then $$\frac{E}{E_1} = 1 + \frac{C_2}{C_3} + \frac{C_1}{C_3} = \frac{C_1 + C_2 + C_3}{C_3}.$$

Of these three capacities, however, whilst C_2 and C_3 can be determined, or are known already, it is more difficult to determine C_1, the capacity of the voltmeter, because of its varying magnitude. In order to make the multiplying power as large as possible, it is clear that C_3 should be as small as possible, whilst C_2 should be large. If C_2 is very large compared with C_1, then we may neglect the latter, the multiplying power becoming $\frac{C_2 + C_3}{C_3}$. But should this not be the case, then it would be necessary to determine C_1. This capacity should be determined for different positions of the movable vane or vanes corresponding to certain voltages, and the results plotted as shown in Fig. 2. Then, for any voltage indicated by the

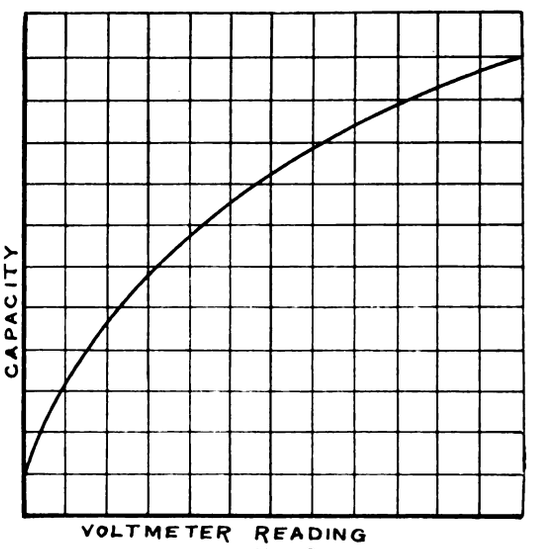

FIG. 2.

voltmeter, C_1 has a certain value, and this can be introduced into the original expression of the multiplying power. Of course, the result will be precisely the same if the capacities are in practical and not theoretical units, because the multiplying power is a ratio, and not an absolute quantity.

The original expression is constant so long as C_1 is constant, provided that C_2 and C_3 are maintained constant, and in the case of an electrostatic voltmeter with large deflections this is not so, although where very small deflections are the rule the assumption that C_1 is constant

Digitized by Google

can be made without any very great error. Also, the multiplying power given above will remain constant if there is no inductance in the voltmeter or the voltmeter circuit; if there is, however, then the reactance will vary with changes of working conditions, and so affect the multiplying power, especially if the frequency of the system should change. The capacity of the voltmeter circuit should be such as not to produce the dangerous condition of electrical resonance.—G. W. BURLEY.

Answer to No. 789 (*awarded* 7*s.* 6*d.*).—When two or more condensers are put in series across an alternating voltage the volts across the different condensers are inversely proportional to their capacities, for the same quantity of electricity must flow into each condenser in a given time, and, since quantity = capacity × voltage, the voltage must divide up across the different condensers in inverse proportion to their capacities. By placing two condensers of widely different capacities, C_1 and C_2, across the voltage to be measured a small definite fraction of this voltage will, therefore, be obtained across the condenser with the larger capacity, and by measuring this fraction by means of a low-reading electrostatic voltmeter or electrometer connected across this condenser the value of the total voltage can be arrived at (Fig. 1).

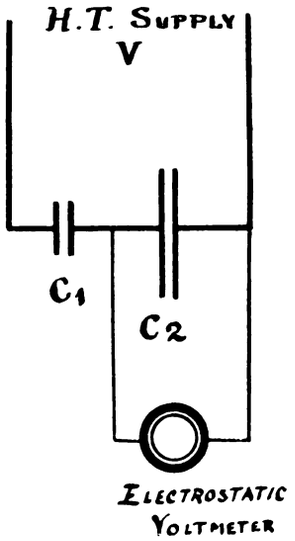

FIG 1.

The multiplying power of the arrangement is obtained thus:

Voltage over C_1 + voltage over C_2 = total voltage = V, and $\frac{\text{voltage over } C_1}{\text{voltage over } C_2} = \frac{C_2}{C_1}$, or voltage over $C_1 = \frac{C_2}{C_1}$ × voltage over C_2.

$$\therefore \frac{C_2}{C_1} \times \text{voltage over } C_2 + \text{voltage over } C_2 = V,$$

or,
$$V = \text{voltage over } C_2 \left(1 + \frac{C_2}{C_1}\right).$$

The multiplying power—*i.e.*, the figure by which the voltage actually measured over the larger capacity, C_2, has to be multiplied in order to obtain the total voltage, V—is $1 + \frac{C_2}{C_1}$. Thus, supposing the capacity of C_2 is made nine times as great as that of C_1, the total voltage, V, would be $1 + 9 = 10$ times as great as the voltage measured over the larger capacity, C_2, and the voltmeter can, of course, be made direct reading by marking the scale to read 10 times the voltage actually applied to the instrument's terminals. Where possible it would be preferable to calibrate the instrument when actually measuring the high voltage by means of its own condensers, as accurate comparisons of condensers are somewhat troublesome to make.

The absolute values of the condenser capacities are not of much importance provided that both capacities are large enough to render the capacity of the electrostatic voltmeter itself negligible in comparison. This is not difficult, however, for even a 200-volt Kelvin multicellular voltmeter has a capacity of only about one ten-thousandth of a microfarad, and the ordinary single quadrant instrument would have considerably less. Quite small capacities such as one-tenth of a microfarad, or even less, would, therefore, be quite allowable.

In order to make the multiplying power of the arrangement independent of changes in periodicity, the two condensers should be identical as regards method of construction, and the dielectric should be of the same quality and thickness in both, for it is only under these conditions that the power factors of the two condensers will be exactly alike, and that the two voltages will be exactly in phase and will allow the equation

Voltage over C_1 + voltage over C_2 = total voltage V

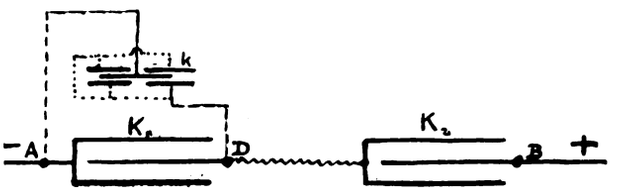
to hold good at all voltages and periodicities. Of course, the power factor of a good condenser is in any case so nearly zero that this precaution would only be necessary for very accurate work and for very wide changes of periodicity. As regards the constancy of the multiplying power of the arrangement, this would depend solely on the constancy of the relative capacities of the two condensers, and in order to ensure constancy in this the condensers should have a solid dielectric—preferably mica—and be kept under constant compression so as to prevent the plates flaking out and reducing the capacity.

It may be mentioned that attempts have occasionally been made to reduce the volts at the terminals of an electrostatic voltmeter by placing a single small condenser in series with the voltmeter across the high-tension supply, but this method has decided disadvantages as compared with the above described parallel arrangement.—Q.

Answer to No. 789 (*awarded* 5*s.*).—The two condensers are arranged in series whilst the electrometer is in shunt with one.

Let v be the highest reading of the electrometer, K;
V = the highest of the new range of readings;
c = capacity of K;
C_1 = capacity of the condenser in shunt with K;
C_2 = capacity of the other condenser, K_2.

The total E.M.F. is applied to the terminals, A and B, of the condensers in series. The E.M.F. at the electrometer



terminals is the same as that between A and D, and is a certain fraction of the whole, depending upon the capacities of the various parts. The quantity of negative electricity on K_2 is equal to its positive charge, and also to the total positive charge on K_1 and K, and, therefore, to the two negative charges on the two latter. Let Q be the quantity on one plate of K_2. Since charge on one plate = capacity × (E.M.F.),

$$Q = C_2 (V - v) = (C_1 + c)\, v.$$

$$\therefore \frac{V - v}{v} = \frac{C_1 + c}{C_2}, \text{ or } \frac{V}{v} = \frac{C_1 + C_2 + c}{C_2}.$$

Neglecting the capacity of K—*i.e.*, c—as must be done, since it is variable (getting greater as the paddles move between the fixed vanes), the following relation holds:

$$V = \left(\frac{C_1 + C^2}{C_2}\right) . v. \quad i.e., \frac{C_1 + C_2}{C_2}$$

is the multiplying factor to be applied to the readings of the electrometer, and applies equally to direct and alternating current. It will be seen that for high voltages either C_1 must increase or C_2 decrease. The capacity of c which has to be neglected determines the minimum size of C_1—*e.g.*, C_1 might be taken equal to 1,000 c. The working current will determine the maximum size. Let C_s = capacity (in series) of the system. Since

$$V = (V - v) + v = \frac{Q}{C_s} = \frac{Q}{C_1} + \frac{Q}{C_2}$$

$$\therefore C_s = \frac{C_1 C_2}{C_1 + C_2}.$$

Digitized by Google

As there is no resistance, the working current, A,

$$A = 2\pi \sim C, V = \frac{2\pi C_1 C_2 V}{C_1 + C_2}.$$

The condensers must be of constant dimensions, and, therefore, mechanically strong. Since the ratio $\frac{Q}{V} = ie$, capacity—has been assumed constant, air must be used for the dielectric. The condensers should, therefore, be of the standard air-condenser type. Mica might be used for a laboratory experiment, but paraffin-waxed paper condensers should be avoided.—E. S.

Answer to No. 789 (*awarded* 5*s.*).—If condensers of capacities, C_1, C_2, etc., be connected in series, and a voltage, V, be applied across the ends, each condenser receives a charge, Q, equal to that of the end condenser. Hence the voltages across the terminals of each are

$$V_1 = \frac{Q}{C_1}, V_2 = \frac{Q}{C_2}, \text{ etc.},$$

$$\text{and } V = V_1 + V_2 +, \text{ etc.}, = Q\left(\frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} +, \text{ etc.}\right).$$

But if the capacity of the combination be C,

$$V = Q\left(\frac{1}{C}\right), \text{ whence } \frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} +, \text{ etc.}$$

The relation between the capacity of any condenser and the voltage across it is then

$$\frac{V_1}{V} = \frac{C}{C_1}, \quad \frac{V_2}{V} = \frac{C}{C_2}, \text{ etc.}$$

and so an extremely high value of V (up to 40,000 volts) may be measured by the reading of an electrostatic voltmeter of moderate range. Unless correction is applied for the latter's capacity—and this is impracticable, owing to variation at different deflections—the condenser across which the voltmeter is shunted should be of relatively large capacity. This is easily attained, as the average capacity of a voltmeter is of the order 10^{-5} of a microfarad. The chief drawback of this method in measuring a continuous voltage is leakage, which unequally affects the ratios; the measurement of an alternating E.M.F. is free from this, but is subject to error with variation in frequency unless each condenser has the same dielectric, owing to inequality of absorption. Obviously the condensers must be of such pattern in any case as to be unaffected by adjacent bodies. With due attention to these points the ratios may be relied on. For further applications of and remarks upon this method, the Institution's *Journal* No. 167 (Edgcumbe and Punga on "Direct-Readin g Measuring Instruments," and discussion) and British Association Report, 1903 (Marchant and Worrall), may be consulted.—ZERO.

Question No 790.—**Make a sketch and describe a mains-charging device suitable for a 1,000-kw. three-core power cable working at 10,000 volts. Explain fully why this apparatus is used on high-pressure alternating circuits.**

Answer to No. 790 (*awarded* 10*s.*).—The cable charger shown diagrammatically in Fig. 1 has been successfully used on extra high-tension systems. It consists essentially of a three-phase transformer with an adjustable water resistance in each secondary. The leads from the primaries terminate in plugs which are very efficiently insulated. The whole apparatus is mounted on wheels. To use the charger proceed as follows: Bring the charger up to the switch you want to close. See that all the secondaries of the charger transformer are open, and then connect the primaries across the open switch (as shown in Fig. 1) by plugging into the holes, made for the purpose, in the terminals of the oil-break switch. Now cut out the water resistance in the secondaries gradually, until the cup of mercury (*c* in Fig. 1) is reached. Close the switch and open the secondaries of the transformer, and unplug the primaries. The charger can then be run on to charge any other cable by repeating the above operations.

Before explaining the principle on which this charger works, it will be as well to show why a charger is used on high-pressure alternating circuits. In a "dead" cable, say, two or three miles in length, with transformers or other apparatus fed from it, there is a large amount of "room," or capacity, which the electricity tries to "fill" as soon as the circuit is completed. The cable and its apparatus, therefore, act like a large condenser. The circuit will also contain resistance and inductance. Now, the impressed E.M.F. of such a circuit may be regarded as being made up of three components—viz.: (1) the resistance component = R C; (2) the inductance component = $2\pi n$ L C; and (3) the potential difference across the condenser terminals = $\frac{C}{2\pi n K}$, where C = current, n = periodicity, L = henry, K = capacity, R = resistance. If these three components be drawn out in the form of a vector diagram, as in Fig. 2, and the capacity is very large as compared with the resistance and inductance of the circuit, it is obvious that, as in Fig. 2, the potential difference across the condenser (A F in Fig 2) is much greater than the impressed voltage, represented by the resultant vector, A H. (The current is here assumed to obey the simple harmonic law, but, as a matter of fact, the first wave would be distorted very much indeed, and this distortion would be less with each succeeding wave until the current wave became normal for the particular circuit.

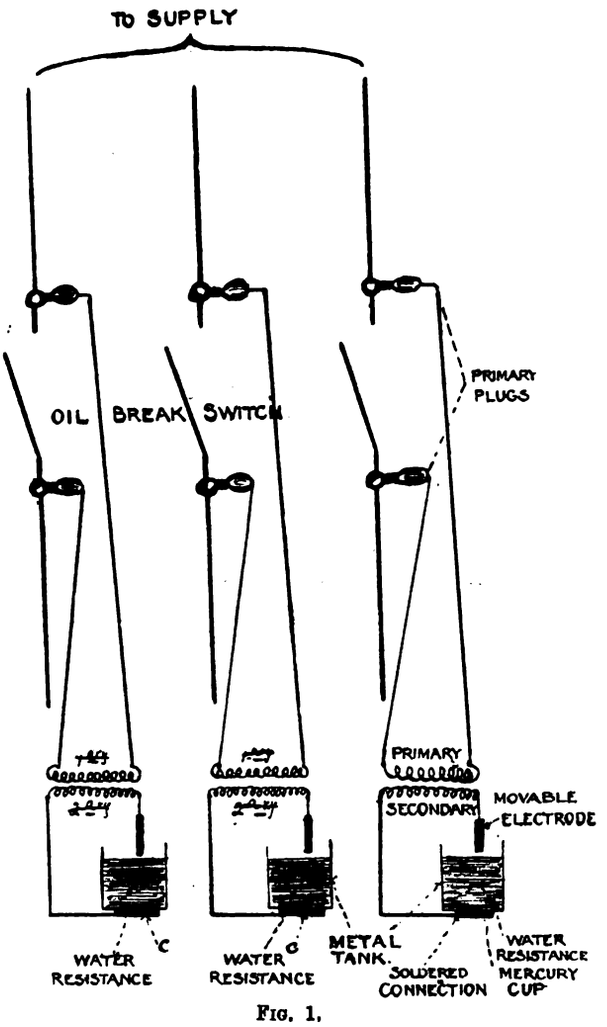


FIG. 1.

We know that the "initial capacity" of a circuit, such as a length of feeder, is very large, indeed, as compared with its resistance and inductance, because it has been observed that at the moment of switching on a large excess current passes into the main. This amount becomes less with each cycle, as mentioned before. If we take the Diagram Fig. 2 as representing an actual case, at the instant of switching on we see that the potential difference across the main which has just been switched on is practically double the working voltage of the system. In practice it has been found that even higher rises take place. This very high pressure may have two immediate and very injurious effects on the circuit: (1) it may, if high enough, instantly puncture the insulation; (2) the very large current may burn the insulation of the cables, and may burn out any apparatus which may be in circuit. If neither of these two things happen, and the circuit is continually switched in directly, the

Digitized by Google

insulation will surely be severely strained and much weakened on each occasion, and will sooner or later break down with disastrous results to the system. But this excessive pressure can be prevented by introducing a large resistance into the circuit. The charger shown in Fig. 1 prevents the objectionable rise by utilising the large primary back E.M.F. of an unloaded transformer, and gradually "charges" the main by loading the transformer. When the secondaries are shorted, only a low back E.M.F. exists in the primary, and practically the full

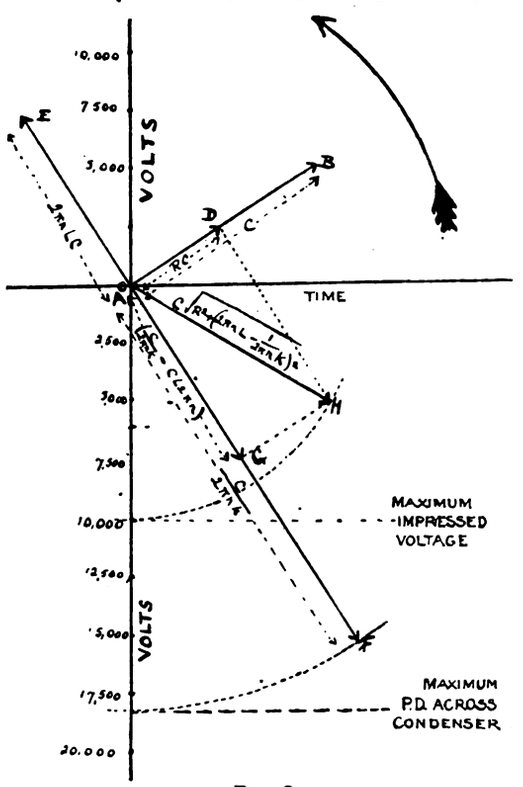

FIG. 2.

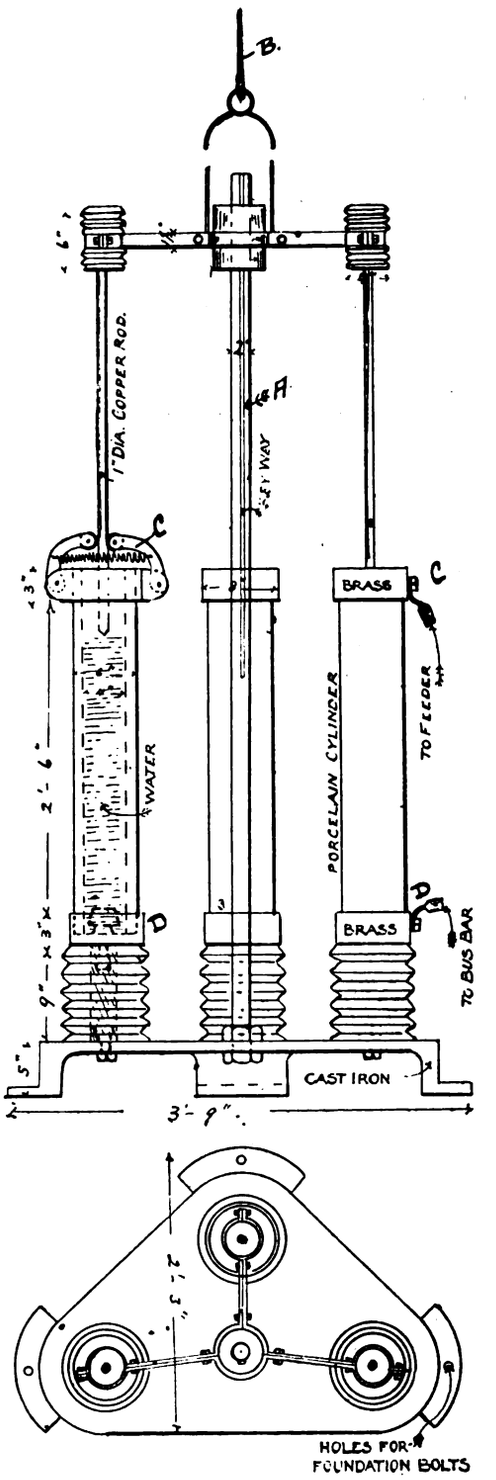
pressure of the system is sending current out into the main. The oil switch can then be closed without fear of any damage being done to the system.—H. A. CARNEY.

Answer to No. 790 (*awarded 7s. 6d.*).—The question of the advisability of providing cable-charging gear has been often discussed, but no definite conclusion either for or against the use of such apparatus has been arrived at. American practice is decidedly opposed to the instalment of this apparatus, and there are very few power-houses in the States so equipped. As other instances of the non-use of this apparatus may be mentioned the Central London and Glasgow equipments with high-tension feeders four or five miles in length. The object in using these gears is to prevent sudden and abnormal rises in the pressure which are said to occur under certain conditions when a feeder is switched directly on to the 'bus bars.

Cable-charging gear may be roughly divided into three divisions: (A) water resistance; (B) separate motor-generator, forming the cable charger; (C) the Partridge arrangement, involving the employment of a three-phase transformer, the primaries being connected in series with the three-core cable, and the secondaries connected up to a non-inductive resistance. Type A being the one that is probably most used, we will now consider the construction of one suitable for a 1,000-kw. three-core cable working at 10,000 volts. As shown in the sketch, this consists of a cast-iron frame, supporting three porcelain cylinder cemented to insulators (size of insulators 9in. by 8in.), the insulators being bolted to the cast-iron framework. The cylinders are 2ft. 11in. long, external diameter 6in., internal diameter 4in. To the bottom ends of the cylinders are cemented brass caps, these caps in turn being fastened to the insulators by means of a bolt and sulphur cement. To the upper ends of the cylinder are clamped brass sleeves, forming cable connectors and guides to the contact rods. These rods are mounted by means of insulators on a movable iron framework, free to slide up or down the central spindle, A, there being a keyway on the spindle to guide the framework in a straight line. The rods are raised or lowered as required by means of a thin wire rope, B, the other end of the rope going to a winch placed on the switchboard, the usual arrangement being that the charging gear is placed under the switchboard gallery and the elevating gear on the switchboard platform. The action of the apparatus is as follows: The feeder before being switched on to the 'bus bars is connected to the sleeve and guides at C by



means of a switch, the bottom contact at D being connected to the 'bus bars direct. Then when the rods are gradually lowered by means of the lowering gear, the voltage on the feeder will gradually rise as the rods approach the bottom contacts. When this occurs the main switch belonging to that feeder may be closed and the cable-charging gear disconnected.—A. V. ANDERSON.

[Other replies to Question No. 790 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

QUESTIONS.

797.—With gas at 2s. 6d. per 1,000 cubic feet and electricity at 1½d. per unit. can the electric arc system show an advantage for street-lighting over the high-pressure gas system in (*a*) initial outlay, (*b*) running costs, (*c*) distribution of light?—S. P.

ANSWERS.

Question No. 790.—Make a sketch and describe a mains-charging device suitable for a 1,000-kw. three-core power cable working at 10,000 volts. Explain fully why this apparatus is used on high-pressure alternating circuits.

Answer to No. 790 (*awarded* 7*s.* 6*d.*).—In the power station I am connected with there was originally no mains-charging device for use with the extra high-pressure long-distance cables. It was found that the cables repeatedly broke down when switching them on. Consequently a Ferranti type of cable-charging apparatus was tried with complete success. This device is shown in Fig. 1 arranged for a two-phase plant. Needless to say, it can be made suitable for single, two, or three phase working. It is simply a water resistance, the apparatus being specially designed for working at high pressures. The iron

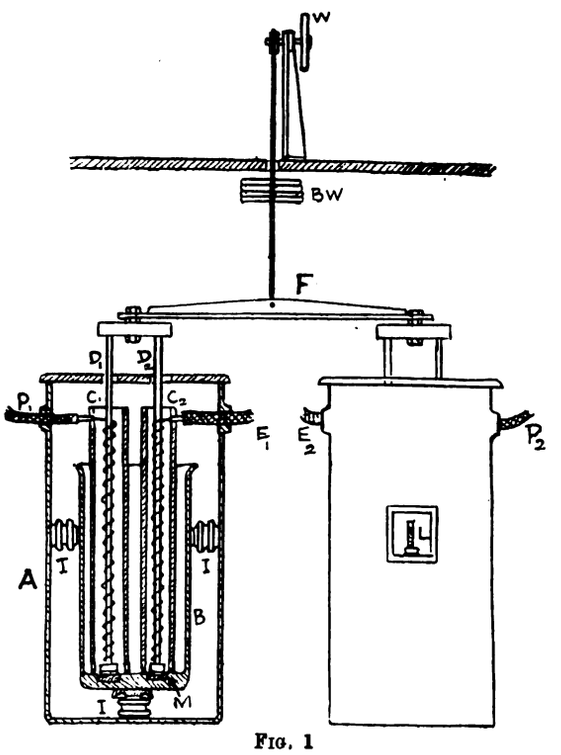

FIG. 1

case, B, contains the water, B is supported by insulators, I, from outer containing case, A, which has a small glass door, shown at L, for inspecting the level of the water. Two long porcelain tubes, C_1 C_2, are fixed vertically in B, resting immediately over two cups at the bottom of the case, containing mercury, M. Two ebonised iron rods, D_1 D_2, have metal caps attached at the bottoms, which dip into the mercury-cups. These metal caps are connected to the cables, P_1 and E_1, by means of flexible copper tapes wound round the iron rods These ebonised iron rods are connected to an insulated block at the top, which is supported by the bar, F. The apparatus is fixed beneath switchboard gallery, and a chain attached to F passes over a chain wheel fixed to a support on floor of gallery, and the weight at F is balanced by balance weight, B W, at the other end of the chain. A handwheel, W, rotates chain wheel and raises or lowers rods, D_1 D_2. The connections to the cable are shown roughly in Fig. 2. A two-way switch, S_1, in No. 1 position connects 'bus bars to cable-charging apparatus, which is connected to feeder, F. The rod, D, is gradually lowered into the liquid, thus gradually raising the pressure of the cable, F, until it is at the same pressure as the 'bus bars. The switch, S, is then put into position No. 2, connecting feeder directly to 'bus bars. To discharge the feeder see that the rod, D, is as far down as possible, put switch, S, in No. 2 position, gradually raise D to top position, and switch off. In a single-phase 2,000-volt system I had some experience with it was the rule to lower the 'bus-bar volts before switching in a feeder the fuse for which had blown. If this was not done, the low-tension volts shown by the pilot voltmeter rose considerably above the normal. At Manchester a separate motor-generator is used for charging the high-tension mains. This motor-generator is switched on to the feeder and the high-tension volts raised to the pressure of the 'bus bars, and then the feeder is synchronised and paralleled. With this method some time is taken in getting a feeder switched on the 'bus.

Another method is the Cowan-Still cable-charging system. A special transformer is used similar to the boosting transformer recently described in the *Electrical Engineer*. Messrs. Cowan and Andrews, in a paper on control of long-distance transmission lines read before the local section of the Institution at Manchester, go very fully into the question of abnormal pressure rises in cables and methods of charging them. Their explanation of the rise in pressure due to switching on a long high-tension cable is as follows: "When the switch is closed, the electrostatic energy stored in the cable may be equal to or greater than the electromagnetic energy stored in the ether surrounding the cable by the current flowing to charge it. This latter energy will be converted into electrostatic when the impressed E.M.F. of the circuit equals the back E.M.F. of the condenser, and the final pressure may consequently double the normal.

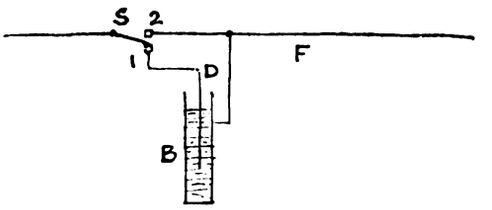

FIG. 2.

In the same way, opening an unloaded circuit may result in a rise of E.M.F. double the normal pressure. One is forced to the conclusion on reviewing the whole question, that circuits having appreciable capacity and self-induction should not be switched on or off, whether loaded or unloaded, suddenly." The system of cable charging first described is a very rapid and good method to use. In the rather unlikely event of anything going wrong with the apparatus, the generator should be run up on the cable.—RESEARCH.

Answer to No. 790 (*awarded* 7*s.* 6*d.*).—This matter of mains charging was fairly fully dealt with by Messrs. Cowan and Andrews in their paper read before the Institution of Electrical Engineers at Manchester two years ago, and I propose quoting from this source fairly fully. Speaking of abnormal rises of pressure in alternating-current circuits occasioned by the sudden opening of a loaded circuit, they go on to say: "While the opening of a circuit under load is the worst condition for causing rises of pressure, rises will also occur when an unloaded line is opened or closed. According to many authorities on this subject, the rise cannot exceed double the normal pressure under these conditions. When the switch on a dead circuit is closed, the electrostatic energy stored in the cable may be equal to or greater than the electromagnetic energy stored in the ether surrounding the cable by the current flowing to charge it. This latter energy will be converted into electrostatic when the impressed E.M.F. of the circuit equals the back E.M.F. of the condenser, the result being that a double quantity of electricity can be forced into the condenser, and the final pressure may consequently be double the normal. In the same way, opening an unloaded circuit may result in a rise of E.M.F. double the normal pressure As a matter of fact, however, a higher pressure than double the normal has been recorded when closing the switch of an unloaded line of 44 miles in length. This

Digitized by Google

increased rise is probably due to some coincidence between the crests of the impressed waves of E.M.F. and the crests of the waves of E.M.F. of high frequency, which accompany the natural oscillations in the cable." The above is the reason for the use of these cable-charging devices, so as at first to only apply a small E.M.F. to the cable on making it alive, and then increasing this until the full voltage and finally closing the main switch.

The first device of this kind I will describe is the Cowan-Still cable-charging system. This consists of a variable induction transformer, which is wound somewhat similarly to an induction motor, with the stator winding also wound half on the movable part; this may be termed the secondary

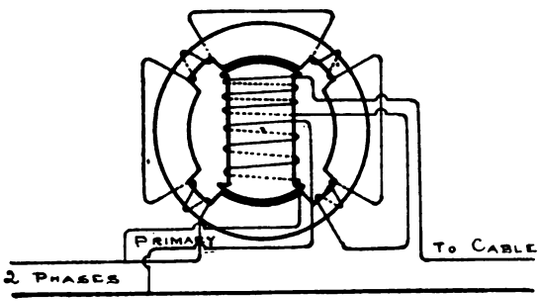

FIG. 1.

of the transformer, one terminal being connected to one 'bus bar, and the other to the cable being charged. The primary or rotor winding is on the movable portion, and is connected across two phases. The idea is that according to the position of the rotor, the pressure applied to the cable will vary from nothing to full voltage, when the cable may be switched in directly. In a certain position the flux due to the primary winding will tend to induce an E.M.F. in one direction in the secondary winding on the rotor, and an E.M.F. of similar magnitude in the other half wound on the stator, the resultant being equal to nothing, and so no charging current will enter the cable. As the rotor is slowly turned through 90deg. the magnitude of the E.M.F. induced in the half of the secondary wound on the stator falls, owing to the primary winding being in a different position relative to it, the E.M.F. induced in the half on the rotor always remaining the same. The resultant secondary E.M.F. applied to the cable hence rises. Similarly, when turned from 90deg. to 180deg., it will be seen that the two E.M.F.'s induced in the two halves of the secondary are now in the same direction, and at 180deg. the resultant is a maximum and is equal to the full supply F M.F. The cable now is switched straight on.

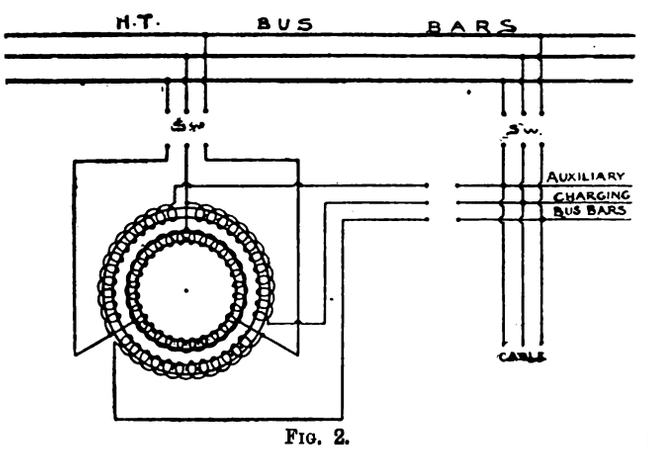

FIG. 2.

Fig. 1 is a sketch showing the idea of this arrangement for just one phase, and Fig. 2 is a diagram of connections for charging the three-phase cable mentioned. It will be seen that the cable is first connected to three auxiliary charging 'bus bars, and then when the full voltage has been applied the main switch is closed. It will likewise be seen that a device of this kind can be used for disconnecting a cable, by slowly decreasing the potential applied to it.

Another cable-charging device, due to Messrs. Ferranti, consists of a water resistance. The cable is first connected to the 'bus bars through long columns of water in tubes, about 3ft. long, in each phase. The length of this water column is then reduced by hand till the contacts at the bottoms and tops of the tubes are touching, when the main switch is closed. This may also be used for disconnecting a cable, as will readily be seen.

In a system with which I am connected, transmitting at 6,000 volts, no such cable-charging devices are in use, but each feeder is fitted with spark gaps which are connected to earth. These seem to be very satisfactory, and it is only necessary to switch the cable straight on. Any abnormal rise of pressure is dealt with by these arresters sparking to earth. They consist of a series of roughened metal cylinders placed one above another, and separated by a narrow air-gap. The top is connected to the cable and the bottom to earth.—E. R. ALEXANDER.

Question No. 791.—Between the rails of a tramway system and the adjacent water-mains pressures up to ·25 of a volt are obtained when the generating plant is shut down. What do you consider is the cause of these potentials? There is an independent combined three-wire and alternating-current supply in the town.

Best Answer to No. 791 (*awarded* 10*s.*).—Differences of potential can be found in most subterranean iron pipes, rails, etc. The currents flowing under these differences of potential are due to one or two causes, and will be found with most lighting and tramway systems with earthed conductors—in fact, since the adoption of earthed conductors made compulsory in some instances by the Board of Trade and universally used on tramways in this country, the earth can hardly be said to be entirely free of stray currents. On the tramway system I superintend, even with traffic suspended there are differences of potential of nearly two volts between the rails and water-pipes. Observations show that the currents are from a neighbouring tramway system, because when this system is shut down the readings drop to ·5 volt, the current flowing from water-pipes to rail. When this neighbouring system starts up the current is reversed—*i.e.*, flowing from rail to water-pipes. When both systems are running the pressures tend to neutralise, and readings only 25 to 50 millivolts are obtained, varying first positive and then negative from rails to water-pipes. The neighbouring system has its rails joined to ours with its fishplates, but not bonded. The difference of potential of ·5 volt obtained when both systems are suspended is probably due to our three-wire lighting system, or it may be due to battery action, which I will explain later. The readings mentioned in the question may be from the local lighting system due to a faulty cable which may be in close proximity to a water-pipe, the leakage current probably attacking the pipe on its return to the station earth-plate if the system has an earthed conductor at the station, thus raising the potential of the water-pipe, or in this case it may be due to battery action.

I have mentioned battery action above, and I will now explain more fully. If two plates of iron are buried in fairly moist earth a short distance apart, differences of potential can be read with a millivoltmeter. I have frequently taken readings of ·25 of a volt with this experiment. The same results can also be obtained between water-pipes and gas-pipes. This is termed an earth battery, and the action is somewhat similar to the ordinary primary battery. If the plates are left long enough in the ground, the action is rather peculiar. When the current leaves a metallic surface buried in the ground, it does not carry with it the decomposed metals, as in a plating bath, and deposit them on the cathode. On the contrary, the products lie adjacent to the surface acted upon, and when the metal is iron they generally form oxides. With a lead service pipe connected to an iron pipe there are two metals which, when buried in the earth, form an earth battery which will cause a current to flow between them when their ends are connected together, as in the case when a cast-iron pipe and a brass nipple are tapped together and attached to a service pipe of iron or lead. With some metals corrosion sets in early and forms a high-resistance contact, and readings cannot easily be obtained, the high resistance breaking up these local earth currents. It was found that the caulking of water or gas pipes sets up galvanic action if the lead touched the iron in any place. I found on an old horse tramway system without a local lighting supply, and miles from any other tramway system, that ·25 of a volt could be obtained between iron pipes and tramway rails, which

Digitized by Google

was undoubtedly due to battery action of the buried iron. Mr. A. B. Herrick, in his paper on "Electrolysis and Earth Returns," read before the New York Electrical Society in April, 1900, and D. H. Maury, in a similar paper read before the American Waterworks Association, May, 1900, experimented and found this battery action to be correct.—I. N. W.

Answer to No. 791 (*awarded* 5*s*).—It is evident, from considerations of the above question, that the pressures which are set up between the rails of the tramway system and the adjacent water-pipes are not caused by any other pressures acting at that time in the system, because the system is not working when the observations of these pressures are taken. Nor is it likely—though it is possible—that the continuous currents of the independent combined system are the direct cause, for faults and excessive leakage are, as far as possible, avoided. The real cause, however, appears to be a sequential cause—that is, a cause composed of a number of causes each acting in turn. When the tramway system is working, there is a drop of potential in the rails not exceeding the Board of Trade limit—the exact magnitude of the drop, however, is of little consequence here. There is, however, an equal drop in the earth from end to end of the system, and this gives rise to earth currents. Now these earth currents will take the path of least resistance, and consequently pass from the rails of the system to the *adjacent* water-pipes. If the intervening medium between the rails and the pipes is moist or wet, perhaps containing acid of some kind, then we have a very crude secondary battery, with the water-pipes and the rails constituting the two poles. This crude secondary battery will, during the running and working period, be getting charged up, perhaps not to more than one volt, and possibly to less than this. When running and working have ceased, this battery has then an opportunity of discharging itself, and hence there is an *active* difference of potential between the water-pipes and the rails. Thus the initial cause acts during the period that the generating plant is at work, and the final cause during the period of rest or "shut down."—G. W. BURLEY.

Answer to No. 791 (*awarded* 5*s*).—The difference in voltage between the tramrails and water-mains is most likely due to an earth in the middle wire of the three-wire network when that system is not in balance, or an earth on one of the outers Suppose that there is an earth on the middle wire at A (Fig. 1), and that the middle-wire current is in the direction indicated, then, as tramrails will be earthed at the station end (indirectly, being connected to earth-plate through earth-current ammeter), and as water-main will be making a more or less good earth at different points along

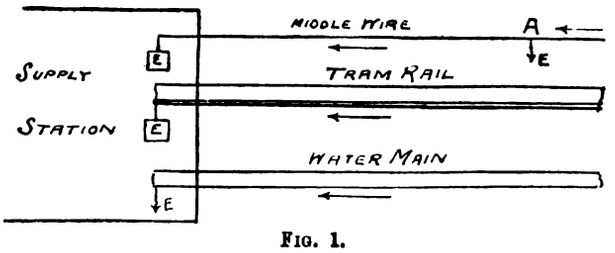

FIG. 1.

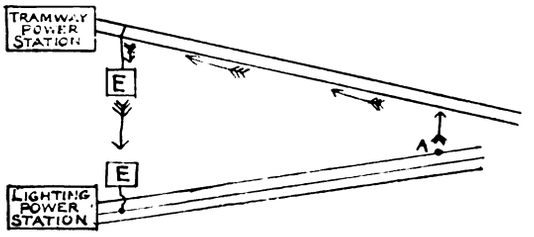
its length, it will be seen that between A and the supply station there will be three paths in parallel, along which the middle-wire current may flow to the station, the respective amounts varying inversely with the resistance to earth at each end of each circuit, together with the resistance of each circuit itself. Then, leaving out of consideration the amount of middle-wire current which returns to the station by the proper path—viz, the middle wire itself—it is more likely that more current will return by the tramrail than by the water-main, since the tramrail is making a good earth at the station end, and the water-main probably only a poor one comparatively.

Now, the potential at the same end of each circuit will be the same—*i.e*, there will be the same fall of potential in each circuit—and, as the tramrail makes perfect earth at the station end, all the fall of potential in that circuit will be due to the resistance of the rail itself, and will be uniform if all bonds are good; but since the resistance of the earth which the water-main makes at the station end probably forms a considerable portion of the total resistance of that circuit, the fall of potential along the water-main itself, although uniform, will not be so rapid as the fall of potential along the tramrail. Hence the difference of potential between these two at any point intermediate between A and the station. If the water-pipe makes good earth, then by following out a similar reasoning bad rail bonds may be shown to be a cause of differences of potential.—G. N. W.

Answer to No. 791 (*awarded* 5*s*.).—This is really the old "earth battery" effect, but under more modern circumstances. The old earth battery consisted of a plate of copper and a plate of zinc buried in the earth. A wire was attached to each, and a feeble current was obtained, generally for driving an electric clock. The E M.F. was very low, but varied with the earth in which the plates happened to be buried—*e g*., if both plates were in clean sandy soil, the E M F. would be very low, but if any acid refuse happened to find its way to the zinc plate, then, of course, the E M.F. would be increased.

In the conditions of the question we have a still more feeble E.M.F., because each "plate" of the battery is iron, one being the tramrails and the other the water-mains; but these are under different circumstances, for the water-mains are buried deep down in clean soil, whereas the tramrails are laid in a busy road soaked with the acid filth of animals, etc., which would easily attack them. There is still a further reason why the tramrails should act the part of positive plate to the water-mains, and that is due to the electrolytic action caused by the electricity used in driving the trams, for this current would, of course, flow from one part of the rail to another on its way back to the dynamo, therefore, one part of the rail would show a positive potential to another part, and, therefore, one part—viz, the negative—would be cleaned by the electric (working) current. This clean part may, for our present purpose, be considered simply pure iron, and being on the surface of the road in contact with the above-named acid filth would, when joined by a wire and galvanometer to the oxidised water-mains, naturally show a slight positive potential for a considerable time after the dynamo had been disconnected. All iron pipes are covered with a thin skin of oxide of iron before they leave the makers. It is very durable, and is not attacked by anything usually found in earth a few feet below the surface.—F. G. A.

Answer to No. 791 (*awarded* 5*s*.).—The difference of pressure observed in the question is undoubtedly due to a leakage current from the three-wire alternating-current supply. In the diagram I have endeavoured to show the



state of things. The power stations will probably be in close proximity, and the tramway rails will be connected to an earth-plate at the power station, as also will be the middle wire of the lighting supply. Now, the tramway rails will provide for the leakage current a path of lower resistance than the earth. In the diagram I have assumed the leak to be at the point A. The current will pass from A to the tramway rails, along which it will flow to the earth-plate at the tramway power station. From here it will pass to the lighting station earth-plate up to the middle-wire 'bus bar. Now, of course, as we have a current flowing between the tramway rails and earth, it follows that there must be a difference of potential between the rails and earth. The water-mains may, of course, be considered as dead earth, and, therefore, when tested with a voltmeter the differences of potential noted are obtained. Apparently the leak is rather a large one, and it is probable that the 25 volt may be measured somewhere near the leak, thus giving a large

Digitized by Google

proportion of the total drop. I mean that ·25 volt probably represents about the total pressure drop along the tramrails of the leakage current.—ERNEST P. HOLLIS.

Answer to No. 791 (*awarded* 5*s.*).—The solution of the problem I should look for in a leakage on one of the outers of the three-wire supply system, to which the tramrails are acting as a large collector, and conveying the current through to the point at which it has least resistance to the passage of the current to the water-pipes, and so by this means back to the middle wire of your lighting supply. It stands to reason that the rails, bonded as they are, will have a lower resistance to the passage of the current than the water-mains, some of the joints of which are of higher resistance. Again, the rails are not earthed right up to the station, an insulated return being run back on to the bond; on the other hand, the water-pipes enter the station itself, hence they would have a lower resistance than the rails between the point where the negative return leaves the rails and the station itself. So that the water-pipes being at earth potential and the rails slightly above would give us the reading the questioner finds to be the case in this particular instance. To determine whether this is the case or not, if your middle wire is earthed at the station only and you now connect your voltmeter between the water-pipes and the rails, on switching off your middle-wire earth at the station your voltmeter will cease to register.—W. T. S.

Question No. 792.—In the Crompton automatic cut-out for automatically placing in circuit a substitutional resistance equivalent to the resistance of the arc, and which is used with 10-ampere, open-type, continuous-current street arc lamps, 10 in series on 460 volts, there are just two coils—one thick wire and one thin wire. The latter coil is in circuit the whole of the time, and apparently does all the work. Explain clearly the necessity for the use of the thick-wire coil, and also the functions which in this particular case it performs.

Answer to No. 792 (*awarded* 7*s.* 6*d.*).—In considering the above query a brief explanation of the precise working of the cut-out will not be out of place. In the accompanying

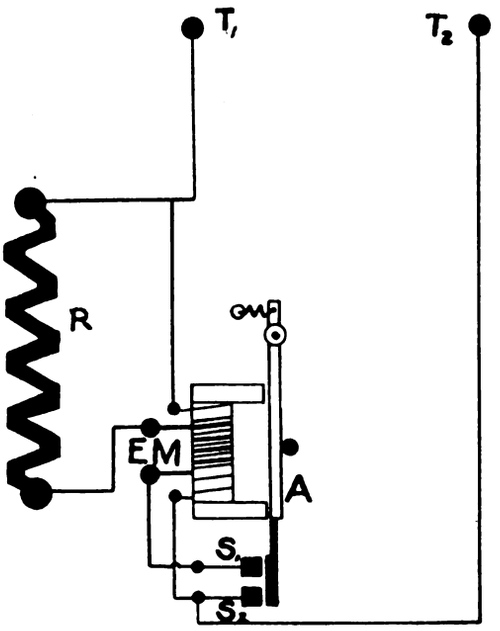


figure we have a diagrammatic sketch of the cut-out. T_1 and T_2 are the two terminals of the arc lamp, the internal mechanism of which has not been included in the sketch. E M is an electromagnet wound with the two windings—one of thick wire and the other of thin wire. These two windings act with one another and *not* against. S_1 and S_2 are two contact studs. A is the armature which, when actuated, bridges the space between S_1 and S_2. R is the substitutional resistance. When, by any means whatever, the two carbons become separated to such an extent that the arc cannot be maintained, then immediately there is an increase in the current passing round the thin wire of the electromagnet, E M. This occurs because, whereas before, when the lamp was working under normal conditions, the thin-wire winding of E M was in parallel with the carbons, now this winding is in series with the main circuit and the full lamp pressure is impressed upon it. This necessarily results in an increase of the current passing through it. This increase in the current results in an increase in the attraction between the electromagnet and its armature, and the spring of the armature holding it back is so adjusted that the armature yields to the new attraction between the electromagnet and itself. S_1 and S_2 are thus brought into contact, and the substitutional resistance circuit is closed. In this new circuit the thick-wire winding is placed. Naturally, now, the current passing through the thin wire will have been reduced in magnitude to its original value. Consequently, the attraction between the electromagnet, E M, and the armature, A, will decrease if the thick-wire winding does not help the thin-wire winding. Therefore, the cut-out will work erratically and unreliably if the thick-wire coils are excluded from the cut-out. The *function* of these coils is to augment the attractive power of the thin-wire coils in order to keep A in contact with S_1 and S_2 until the carbons come into contact again. When the carbons of the lamp are brought once more into contact, the current passing through R, and, therefore, round the thick-wire coils, will decrease, and the attraction between the electromagnet and the armature will also fall off, until, when it has reached a certain value, the spring acts and the armature is released. This release opens the substitutional resistance circuit at S_1 and S_2, and the lamp then works normally.—G. W. BURLEY.

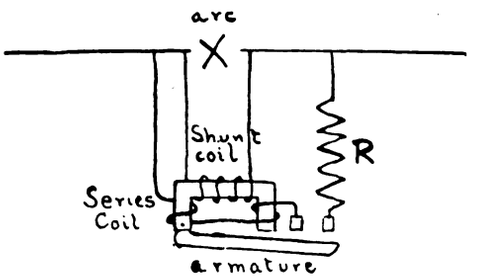
Answer to No. 792 (*awarded* 7*s.* 6*d.*).—Where there are a number of arc lamps in series across 460-volt mains, it is important that the failure of one arc lamp should not cause the rest of the lamps in series with the defective arc to go out. To prevent this, an automatic arrangement is fixed in the case of the lamp to cut it out if it becomes faulty. A fine-wire coil is connected across the two carbons, forming a shunt across the arc itself. It is evident that if the carbons became too short in one lamp, the mechanism would be unable to feed the carbons any closer together, and thus the arc would get longer and longer. The potential difference across the arc would rise, more current would pass round this fine-wire coil until it became strong enough to raise the armature and insert the substitutional resistance. There would be the same pressure drop in this resistance as there would have been if the arc had been working; consequently



the other lamp would be unaffected. The potential difference across the terminals of the fine-wire coil will now fall to normal, and the armature would be released if it were not for the thick-wire winding, which is now carrying all the current, and, therefore, keeps the armature up in position. This thick-wire winding is generally dispensed with in constant-potential circuits, as the voltage drop across the substitutional resistance can be arranged high enough to send sufficient current round the shunt winding to keep armature of magnet in position. The series winding is necessary for arc lamps working on constant-current circuits, because in that case no resistance is substituted, but the arc simply short-circuited. The carbons will thus have no potential difference across them, and there will be no current flowing through the shunt, and if it were not for the series turns the armature would fall, switching off all the arcs in series with the faulty one, and as the pressure would no doubt be high, a continuous arc would be set up, burning away the metal contacts.—RESEARCH.

[Other replies to Question No. 792 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

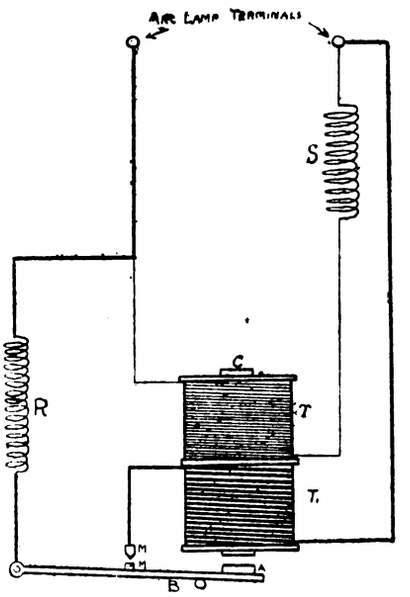
798. A short-circuit occurred across two of the terminals of a 50-h.p. three-phase motor when running at full load. The motor-house is connected to the power-house by an overhead line consisting of three bare copper wires No. 4 S.W.G., placed one above the other, with a spacing of about 10in. between them. The line consists of two short spans, the intermediate support being an iron bracket on the corner of the power-house, which bracket is also situate much higher than the support on the motor-house, this span having an inclination of about 30deg. to the horizontal. Concurrently with the short-circuit on the motor several flashes were seen between the top and middle lines of the motor-house span. The wires were badly burnt and pitted on *both spans*. A distance of several feet, however, on either side of the intermediate support showed no signs of burning. A main 300-ampere fuse in the power-house was blown, while the 120-ampere motor fuse was overheated only. The weather was fine and calm. We have had a similar occurrence before when using a different make of generator, both generators being of the revolving-field type, 330 volts, 42 ~, and of modern construction, motor and generator A wound. Can any of your readers furnish an explanation of the arcing on the line.—F. E. H.

799. An electrostatic extra high-tension voltmeter is continually giving trouble through the metal parts corroding. What is the reason of this?—P. D.

ANSWERS.

Question No. 792.—In the Crompton automatic cut-out for automatically placing in circuit a substitutional resistance equivalent to the resistance of the arc, and which is used with 10-ampere, open-type, continuous-current street arc lamps, 10 in series on 460 volts, there are just two coils—one thick wire and one thin wire. The latter coil is in circuit the whole of the time, and apparently does all the work. Explain clearly the necessity for the use of the thick-wire coil, and also the functions which in this particular case it performs.

Answer to No. 792 (*awarded* 5*s.*).—The accompanying diagram shows the connections for a cut-out used in connection with continuous-current arc lamps connected in series with one another. It will be seen that the thin-wire winding, T, of the cut-out is in series with the shunt winding, S, of the arc lamp, and that both are connected across the arc lamp terminals. When the carbons burn away, or stick apart in any way, the whole of the current, still of the same strength, has to pass through the shunt circuit and would soon destroy it, but the coil T is so adjusted that this increased current passing through it magnetises the core sufficiently to raise the armature, A, and with it the lever, B. This lever, B, carries with it a small contact stud, M, which, when it is raised, comes in contact with another stud, M_1, connected to one end of the thick coil, T_1, on the cut-out. R is a resistance coil equal in value to the resistance of the arc, and when the above action takes place it becomes connected in series with the thick coil, T_1, on the cut-out, and also in series with the other arc lamps in the circuit. This thick coil, T_1, and resistance coil, R, now carry the current which formerly traversed the carbons, so that the shunt circuit again carries only its normal current. The heavy current through the thick coil of the cut-out still keeps the core, C, magnetised sufficiently to keep the lever, B, in position, and thus maintains connection between M and M_1. The insertion of this resistance after any arc lamp has burned out maintains the correct potential drop



across the other arc lamps in the circuit, so that they burn under the same conditions as before.—B. W.

Answer to No. 792 (*awarded* 5*s.*).—The necessity of the thick-wire coil will, I think, be obvious on inspecting Fig. 1. The functions which it performs are as follows: When the lamp is burning steadily the whole current flows from the positive terminal through the series coil, S, then part passes through the carbons and part through the shunt coil, T, which has in circuit the fine-wire coil on the cut-out, C, to the negative terminal. Now, when the main

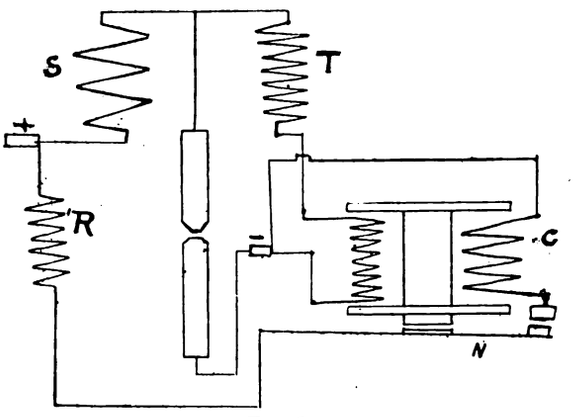


FIG. 1.

circuit is broken, the whole current strength has to pass through the shunt circuit, and might soon destroy it; but the fine-wire coil on C is so adjusted that when this increased current passes through it its core becomes sufficiently magnetised to attract the lever, N, closing the circuit through the substitutional resistance, R, and the thick-wire coil on C, which is wound to assist the fine-wire coil on C; because the latter coil will now have its current diminished, and the circuit would be repeatedly made and broken were it not for the thick-wire coil on C. The current will also be diminished through the series coil, S; the brake will therefore be free, and if only a portion of the carbon has broken off the arc will be re-established, when the current flowing through the thick-wire coil on C will be reduced, and the cut-out circuit disconnected.—H. M.

Question No. 793.—A battery working in conjunction with a reversible booster on a traction load has recently been overhauled and all sediment removed from bottoms of cells. Since then it has been

Digitized by Google

noticed that large lead trees have been forming on a lot of the negative plates, causing a lot of trouble by short-circuiting cells. Would the fact of using acid out of an old battery, that has been idle for months, to top up the cells after overhaul cause the trouble, and could some reader give a remedy for same; also explain the cause of trees forming?

Answer to No. 793 (*awarded 7s. 6d.*).—It seems curious that many engineers find so much mystery surrounding the cause of defects which develop in storage batteries. It seems pretty certain to the writer that most troubles can be traced to the failure of battery attendants neglecting to give the battery the treatment which is generally acknowledged to be essential for its proper maintenance. One of the most important conditions for satisfactory results, and one which probably receives the least attention, is that the electrolyte must be pure. "A. B. C." should have the acid tested, and if it is found to contain impurities, then the acid should not be used. There are two main causes which the writer believes will bring about the formation of so-called lead trees: (1) impure electrolyte, (2) battery being worked at too low an efficiency.

1. Let us examine No. 1 cause. It is well known that impurities in the electrolyte causes clogging of the pores in the active material, and in some cases this takes place in patches. In other words, this clogging may be said to be analogical to corrosion in a boiler, inasmuch as sometimes corrosion is general and sometimes local, the local corrosion being generally distinguished from the general corrosion by being called "pitting"; so, too, the clogging of the pores in the active material of a battery is sometimes general and sometimes local, or in patches. Now examine the effect of these patches. They vary in size from that of a threepenny to a sixpenny piece. They are composed of impurities which have been deposited on the plates, and which produce with the active material on which they become deposited, a couple, which causes local action. The result of this local action is that the active material in close proximity becomes n time disintegrated. As the paste gradually becomes loosened in powder form it falls from the sides and bottom of the patch to the bottom of the cell, but that from the top of the patch comes in contact with the impurities, and is held there; this increases the action, and so the process continues until the loosened paste and impurities accumulate, and so form a ledge, or what is sometimes incorrectly called a growth. As soon as this so-called growth or lead tree assumes appreciable size, they increase in size rapidly. The distance, and consequently the resistance between the plates at this point is reduced, and this again increases the amount of current passing until local or internal discharge results. If allowed to remain, these lead trees soon bridge across the plates and causes short-circuiting. All so-called growths should be removed by means of a thin piece of wood as soon as possible.

2. If the efficiency of a battery be kept low, it follows that the amount of current put into a battery is much more than the amount given out. During charge the current flows from the so-called positive to negative plates, and the direction of current causes the impurities to be deposited on the plate to which the current flows. That is to say, the impurities during charge would be in contact with the negative plates, and during discharge in contact with the positive plates. When, therefore, the efficiency of a battery working in conjunction with a reversible booster is kept low, it usually infers a greater time is taken for charges than discharges. It will, therefore, be seen that under such conditions the impurities will be against the negative plates for longer periods than they would be against the positive plates, and, consequently, they are more likely to become permanently deposited on the negative plate, and this is one reason why so-called growths or lead trees are almost invariably found on the negative plates.

From the above it will be obvious that a combination of 1 and 2 would have a very serious effect on a battery. Another cause which might partly arise out of No. 2 is imperfect circulation. Hence these lead trees are frequently found quite close to the glass separators where the electrolyte is, in some cases, somewhat stagnant.—C.

Answer to No. 793 (*awarded 7s. 6d.*).—It is probable that "A. B. C.'s" trouble is caused, as surmised, by using the acid from an old battery to top up the cells. After standing so long unused this acid probably contains some lead sulphate, or possibly also nitrate, and oxides in solution or suspension. The sulphate, although insoluble in pure water, is slightly soluble in sulphuric acid, while the oxide is slightly soluble in even pure water when air is present. Possibly also dust settling in the disused cells has caused the formation of small quantities of other soluble organic salts of lead, such as the acetate. Similar troubles are caused by ordinary impure commercial sulphuric acid, which often contains lead sulphate, nitrate, or other salts in solution. The action of the lead trees forming is probably purely an electrolytic one. The efficiency of a battery being below unity (perhaps 70 per cent.) it will receive more charging than discharging: therefore, the balance of current will be through the liquid to the negative plates, and the lead will, therefore, be deposited from the salts in solution on these plates, forming the lead trees. So long as any lead *remains* in solution in the acid there does not appear to be any remedy for the trouble. If "A. B. C." wishes to save the acid, he might try *with caution* the addition of a small quantity of sodium sulphate (Na_2SO_4), or, better still, of sodium carbonate (common washing soda), not exceeding one ounce to the gallon of acid solution. Both of these have been used as a cure for "sulphating" in cells, but in the present case their action would be to precipitate as insoluble sulphate or carbonate any soluble lead salts in solution. If practicable, it is preferable that the cells should be cut out one or more at a time (care being taken not to "short" them), the acid siphoned off, and the sodium salt completely dissolved in it before pouring it back into the cell. This should be done in a reasonably short time, to prevent the spongy lead negative plates oxidising much in the air, although some time should be allowed for precipitate formed (if any) to settle to the bottom of the acid before it is returned to the cells. If "A. B. C." can arrange for a supply of sulphuretted hydrogen gas and can put up with the "stink," he can test for the presence of any serious quantity of lead in solution by passing this through the acid, and can remove the lead as a black precipitate of lead sulphide, which should be allowed to settle before returning the acid to the cells.—X. Y. Z.

Answer to No. 793 (*awarded 5s.*).—It was quite a wise and proper thing to remove the sediment and to clean the battery cells, and if the acid from the idle battery was in good order no objection could be urged against using it. The first thing to consider now is whether the acid is of the proper strength—viz., 1,200deg.—when the battery is fully charged. If not, make it so, and push down all the "lead trees" by means of a wooden or ebonite lath. Then continue the charging for half an hour after all the plates give off gas in order that any nitric acid and any hydrochloric acid in the electrolyte may be decomposed and eliminated as gas. These two acids, if present, would make soluble salts of lead, and so enable the lead trees to form when the battery is charging and also when standing idle. Repeat this treatment three or four times, each time pushing down all the "lead trees" and making certain that no cell is short-circuited. I have known this simple treatment quite successful. The lead trees may be formed by some impurity in the lead plates, and, if so, they are difficult to get rid of; but this is not probable, because all makers know that impurities in the plates are fatal to the efficiency of the battery, and, again, it is not easy to see how the trees could form without some soluble salt of lead actually dissolved in the electrolyte. The only remedy for this would be to discharge the battery slowly and to throw away the whole of the electrolyte as useless. The plates should be well washed with clean cold water, brushed, rinsed, and replaced in the cells. Best brimstone sulphuric acid should then be carefully poured into clean rain, or, better still, cold distilled water, with great care and constant stirring. This must then be left for some hours until quite cold, when its specific gravity should be adjusted to 1,190deg., and it may be poured into the cells and charging started, which will bring the gravity of the electrolyte up to 1,200deg., and no more trouble would be likely, because during discharge any metal soluble in the electrolyte, such as zinc or iron, would be removed from the grey plates

Digitized by Google

and dissolved by the electrolyte, and this would have been thrown away. I, however, omitted to mention above that possibly, though improbably, the electrolyte of the recently cleaned cells might be very much too strong. If so, its gravity would be greater than 1,200deg., and it would require water adding, but it would have to be much too strong, probably 1,700deg., to cause "lead trees." Lead is slightly soluble in very strong oil of vitriol. The "trees" are formed by electrolytic action, which may be in the charging current or it may be due to local action on the plates, caused by some such metal as zinc or iron acting in the presence of some soluble salt of lead, as the nitrate or chloride dissolved in the liquid. Common oil of vitriol often contains nitric and nitrous acids as impurities, but they would be decomposed by the hydrogen set free during charging and discharging. However, it is always best to use the purest brimstone sulphuric acid for accumulator work. It gives the best results, and often saves a lot of trouble. The cost is not great, and it is only once—*i.e.*, at starting.—F. G. A.

Answer to No. 793 (*awarded* 5*s.*).—It would be advisable to carefully examine the cells before taking extreme measures; when cells have been overhauled it is quite a common occurrence for them to scale badly for a time, therefore the trouble may not be very serious. Going round the cells and pushing a slip of wood between the plates should remove the abnormal growths; if simply due to fresh setting up, the trouble will soon disappear. In case the growths should persist, the cause may be attributable to faulty electrolyte. Should sulphuric acid used for accumulators contain chlorides, the chlorine is almost certain to be given off during the time the cells are in use, and will inevitably show itself by growths on the plates. There are, however, several other causes that may be looked for. Have the cells been thoroughly charged before being put on discharge? Cells that are charged very slowly, particularly when nearly run down, are apt to throw off shoots between the plates. On the other hand, the battery may have been subject to sudden and heavy demands for current, this may have caused the paste to swell and fall out. This is a frequent source of trouble with an old battery. The remedy appears to be, make sure that the conditions of working are all right, and, if this is so, test the electrolyte. Faulty working can easily be remedied if the electrolyte is unsatisfactory; the only thing to do is to refill the cells. Doctoring accumulators generally ends in the resulting "cure" being worse than the disease.—M. M.

Answer to No. 793 (*awarded* 5*s.*).—The lead trees are due to a chemical lead compound which the acid liquor now contains in solution in sufficient quantity to give trouble. On charging the battery this soluble lead compound is decomposed by electrolysis, and the lead is deposited on the negative plate as lead trees. The bottom edges of the plates, or along the edges of the separators, are the surfaces where deposition generally occurs. This is probably because there is a more rapid circulation of the liquor along those parts, but wherever deposition begins it continues at that point instead of coating the plate evenly, and eventually produces a "short." The acid from an old unused battery, if otherwise normal, could not do any harm. The pure acid of our accuumulators—that is, acid free from injurious impurities—always contains a small quantity of lead in solution, and this is deposited on the negative plate during charging, but it is a fine uniform deposit, only noticeable after long periods of work. It gives no trouble, but is rather an advantage. One cannot say how the soluble lead compound has got into the liquor without knowing all the facts relating to the removal of the sediment, but it is probably a "salt" of some mineral acid, such as hydrochloric. Soluble chlorides of lead would eventually be formed if either acid or plates came in contact with common salt, sal-ammoniac, soldering solution, urine, or any other substance containing a chloride. Perhaps the compound may be nitrate of lead, which would result from contact with nitre or any other nitrate or from nitric acid.

As to the remedy. I know no other than the regular working of the battery. If the compound be a chloride then the characteristic smell of chlorine may possibly be detected, especially on beginning to charge the battery after discharge. Fortunately, the compounds sulphuric acid and a peroxide (necessary for generating chlorine gas from a chloride) occur in the battery, and it will be found that the combined effect of electrolysis and chemical action will be to clear the liquor of any chlorides it may contain by expelling the chlorine as a gas. In the same way the liquor will be cleared of nitrates, the nitrogen being expelled as a gaseous oxide, so that unless the amount of impurity is so great as to render working impossible through "shorts" there is hope for the battery.

It may not be out of place to draw attention to evidence given at the enquiry into the A 8 submarine catastrophe. The battery of a sister boat was flooded with sea-water and chlorine gas was given off as a result of it. Possibly the "lead trees" are not lead, but some other metal, such as iron or zinc, which has been dissolved from galvanised-iron pails or other iron articles. If this be the case, the shorts may gradually disappear, probably from the deposited particles which are shoved off the plate and fall to the bottom amongst the mud from the positive plates, becoming oxidised to Fe_2O_3, in which case the battery acid would have no further action on them.

In justice to the person responsible for the battery, the battery-room ought to be locked or well guarded. It is quire easy for a viciously-disposed person to introduce in two minutes a common substance which would spoil the battery.—F. P. S.

Question No. 794.—Describe the method of arranging the stator windings of two or three phase motors with a view to speed regulation. Is it possible to arrange a 12-pole winding so as to reduce to eight poles?

Best Answer to No. 794 (*awarded* 10*s.*).—The principal methods adopted for varying the speed of polyphase induction motors may be classed under three heads—viz.: (1) by the insertion of non-inductive resistances in the rotor circuit; (2) by changing the number of poles; and (3) by tandem control, or, as it is sometimes termed, the "cascade connection." The first method may be suitable where the speed is only to be varied within small limits, but even then the regulation is obtained only by a sacrifice in the efficiency. This method is equivalent in principle to varying the speed of a shunt motor by inserting resistance in the armature circuit. The third method involves the use of two separate motors, and is similar in principle to the series-parallel control of continuous-current motors. It possesses many advantages for traction work, but up to the present has not found much use for stationary work.

The second method is one which is the most practicable for workshop and stationary work, and is dealt with below, polyphase motors only being considered. The synchronous speed of an induction motor is given by

$$s = \frac{\sim}{p} \times 120;$$

where s = synchronous speed in revolutions per minute
$\sim$ = frequency of supply; and
p = number of stator poles.

Thus, by reducing the number of poles by one-half, the synchronous speed is doubled. We will briefly investigate the relations existing in an induction motor before discussing the stator connections for pole changing. The relation existing between voltage and flux is (for a three-phase motor) given by

$$E = 4{\cdot}2\ T\ N\ M \times 10$$

where E is the "internal" E.M.F. per phase, T the number of turns in series per phase, M the flux per pole linked with the turns, T, and N the frequency in cycles per second.

Consider the case of an ordinary three-phase induction motor with squirrel-cage rotor, and suppose the motor is wound for four poles. We will investigate briefly the alterations required in order to enable motor to run with four and with two poles. We will suppose, for the purpose of this investigation, that the motor is wound for 200 volts and 50 ~. The stator has 36 slots, and there are 22 conductors per slot, the connection of phases being Y. Thus from the above formula we find the flux per pole, M, to be ·407 megaline. Now, in converting this motor into one with two poles it is desirable to keep the gap density the

Digitized by Google

same, and consequently the flux, M, will have twice the value found for the case with four poles. Therefore, since the voltage is the same, the number of turns in series per phase must be one-half of that for the four-pole motor. Thus this motor can very simply be converted from four to two poles by taking a tapping from a point midway in the winding of each of the phases. These three additional leads are connected on to the line in place of the three original terminals, which are now connected together, and we have a two-pole motor. Fig. 1 will serve to make this point clear. When the double-throw switch is thrown "down" the motor has four poles, and when thrown "up" the motor has two poles, the connections made by the switch being shown by the small sketches to the right in the diagram.

It will be observed that the turns in *series* per phase are, for the two-pole connection, one half of that for the four-pole connection. Let us now investigate the operation of the motor for each of these cases. The magnetising current of an induction motor may be obtained from the expression,*

$$i_e = \frac{B \cdot 1{\cdot}6\,\Delta}{t\sqrt{2}};$$

where i_e is the magnetising current, Δ is the radial depth of air-gap in centimetres, and t is the number of turns in series per pole per phase. A brief inspection of this equation will show that the magnetising current is the same for both the four-pole and two-pole connection. It should, however, be pointed out that the magnetising current will be probably greater with the two-pole connection than with the four-pole. This difference will be

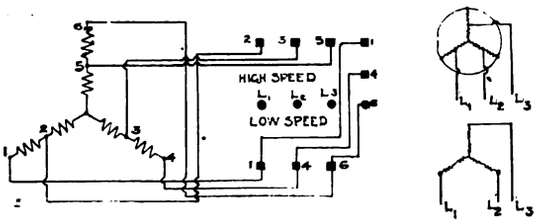

FIG. 1.

marked if the motor is originally designed for four poles, as with the two-pole connection the density in the iron at the back of the slots will be increased considerably, and incidently it may be mentioned that the core loss may be increased so much as to lead to excessive heating.

Adopting Behrend's expression for the leakage factor,†

$$\sigma = \frac{c\,\Delta}{\tau},$$

where σ is the leakage factor, τ the pole-pitch in centimetres, Δ the depth of air-gap in centimetres, and c a factor which, according to Behrend, is "dependent on the shape and size of the slots and upon a great many other conditions of which we are still profoundly ignorant." Now, for the motor under consideration, c and Δ are constant, and τ is increased for the two-pole connection to double its value for the four-pole connection. Now, σ is defined as the ratio of

$$\frac{\text{magnetising current}}{(\text{ideal short-circuit current} - \text{magnetising current})},$$

and as the diameter of the circle in Heyland's diagram is given by (ideal short-circuit current – magnetising current), we see that for the two-pole connection the circle has twice the diameter of that for the four-pole connection. As the diameter of the circle is proportional to the output from the motor, it is apparent that the output of the motor will be doubled when connections are changed from four to two poles.

Fig. 2 and 3 show further diagrams of connections for changeable pole motors similar to the one discussed above.

* "The Induction Motor," B. A. Behrend, p. 15.
† "The Induction Motor," B. A. Behrend, p. 36.

Fig. 2 is a somewhat modified form of connection to that shown in Fig. 1, while Fig. 3 shows the connection when the stator windings are delta connected. In Figs. 2 and 3 the motor runs on the "low speed"—*i.e.*, with the larger number of poles—when the double-throw switch is thrown "up." Throwing this switch "down" connects the stator windings (as shown in the small sketch to the right) and the motor runs on the "high speed."

In connection with speed regulation of induction motors, attention must be drawn to the work done by Mr. C. Wüss (of the firm of Wüst and Co., Seebach-Zurich) in developing what he terms a "multi-speed" induction motor. The motor was described in an article on "The Speed

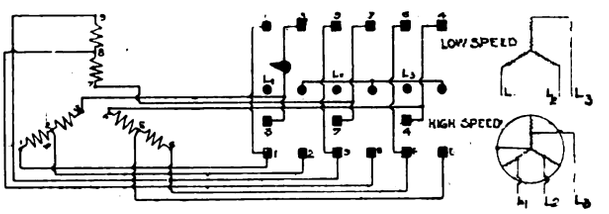

FIG. 2.

Regulation of Three-Phase Motors," which appeared in the *Electrical Engineer* for Nov. 13, 1903. This article should be read by all those interested in the polyphase induction motor, as not only is a description given of this multi-speed motor, but numerous curves showing the operation of induction motors for changeable pole work are included, which in themselves are worth studying.

It may be mentioned that the multi-speed motor consists of a number of stators—two, three, or four, according to speed variation required—arranged in one common housing. Rotors corresponding to these stators are arranged along a common shaft. As an example, we may take the case of what is termed a "three-step" motor. One of the stators is wound, say, for four poles, another for six poles, and another for eight poles, the rotors being wound to correspond. By means of a suitable controller one or other stator is put into circuit, and also various combinations of the individual stators can be made enabling a great variety of speeds to be obtained. In the above-mentioned article some interesting data are given of a three-step, 3-h.p., 50 ~ motor, having the individual stators (or elements) wound for four, six, and eight poles. With various combinations of the elements, speeds from 670 r.p.m. to 1,500 r.p.m. were obtained, the maximum output at the lowest speed (670 r.p.m.) being 6·7 h.p. This multi-speed motor possesses many advantages

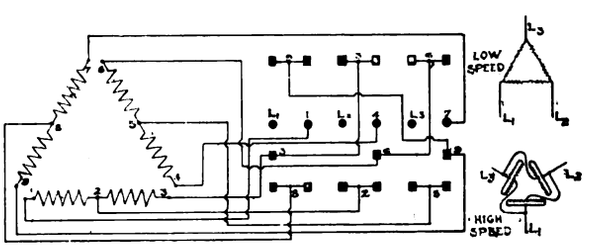

FIG. 3.

(especially where a greater horse-power is required at the lowest speed), and the power factor and efficiency is maintained high at all speeds.

The point raised in the question, *re* arranging a 12-pole winding to reduce to eight poles, would be impracticable in the ordinary form of induction motor on account of the great number of connections that would have to be brought out from the winding. Assuming that the stator has the "rectangular" type of winding, and that for eight poles this winding is arranged with 100 per cent. pitch, then to convert this into a 12-pole winding the coils would have to be reconnected to give a pitch of 66·6 per cent., which would be impracticable.—MONOPHASE.

[Other replies to Question No. 794 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

800. Will a Kelvin multicellular voltmeter give the R.M.S. volts when connected across the secondary of a pressure transformer? The high-tension pressure is 2,000, and the transformer ratio 20 : 1.—H. C. H.

801. Show how to calculate the ampere-turns needed to balance the armature reaction of a polyphase alternator working at power factor cos ϕ.—X. X.

ANSWERS.

Question No. 794.—Describe the method of arranging the stator windings of two or three phase motors with a view to speed regulation. Is it possible to arrange a 12-pole winding so as to reduce to eight poles?

Answer to No. 794 (*awarded* 7*s.* 6*d.*).—The method of speed regulation by pole changing has often been employed where continuous running at two or more speeds is involved. Owing to the complication of the switchgear, as well as to the unsatisfactory conditions under which the machine would be running at the lowest speed, more than two speeds are seldom attempted by this method, and these speeds are usually in the ratio of 1 : 2. The rotors of such motors would generally be of the squirrel-cage type, as these are equally suitable for all numbers of poles. If, however, a wound rotor is essential from torque considerations, two independent windings would have to be put on it—one for each number of poles. In most cases these two windings would not involve any additional slip-rings, as both could be connected to the usual three slip-rings, one or the other winding alone being active according to the number of stator poles in use. With this rotor arrangement the starting current is increased owing to the partial short-circuiting of the active winding by the inactive one; but, unless a comparatively large starting torque is required, this is not of much importance. When running normally, the rings are in any case short-circuited so that the running conditions would not be affected.

With regard to the stator, the same plan of two independent windings can, of course, be employed, and though this involves the use of slots of practically twice the normal size, the switchgear is simple (merely a three-pole main throw-over switch putting one or the other winding into circuit), and the working conditions are better than if a single winding is recoupled to suit both speeds. For the sake of economy in material and space, however, the latter arrangement of a single stator winding is usually employed. This winding is arranged exactly as in a standard motor, except that additional ends must be brought out to enable alternate coils to be reversed. The span of the coils and the width of the coil side would usually be those corresponding to the larger number of poles—*i.e.*, they would be exactly the same as in a normal motor wound for the larger number of poles alone. In some cases, however, especially when the machine is intended to run most of the time with the smaller number of poles, it will be more satisfactory to make the span of the coils and the width of the coil sides something between those corresponding to the larger and those corresponding to the smaller number of poles—*e.g.*, a span of $1\frac{1}{3}$ times the normal span corresponding to the larger number of poles. The case of a four-to-two pole, three-phase, star-connected stator winding with one coil per phase per pair of poles (of the larger number of poles) is represented in Figs. 1 and 2.

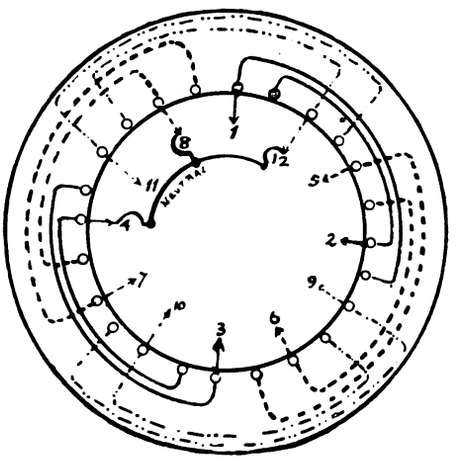

FIG. 1.

Fig. 1 shows the arrangement of the coils, and the ends are numbered to correspond with the diagram of connections and switchgear given in Fig 2. It will be seen that nine leads are required between the stator and the change-over switch in this three-phase case. When the switch is on one side the coils form four poles (alternately north and south), whilst on the other side the reversal of one coil per phase is accomplished, and the motor becomes a two-pole one. In the latter case there are twice as many magnetising turns looped with each magnetic circuit than in the former case, and since the total flux per pole remains unchanged (provided the terminal voltage and the total turns per phase in series remain unchanged) the magnetising current becomes approximately halved. The leakage flux per ampere is much the same in the two cases, so that

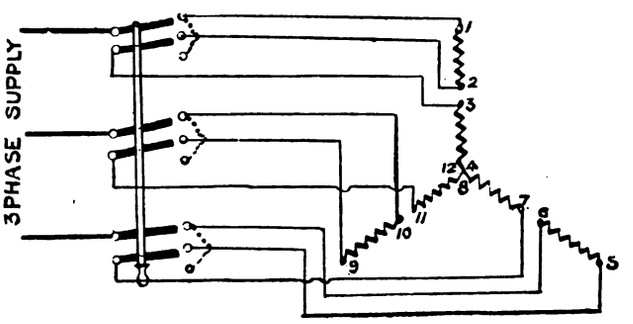

FIG. 2.

the short-circuit or standstill current remains about the same whichever number of poles is in use. This short-circuit current is a measure of the maximum possible horse-power which the machine can develop, so that this maximum horse-power remains unchanged, and since maximum torque $\propto \frac{\text{maximum horse-power}}{\text{speed}}$, the maximum torque is about double as great with the low-speed connection than with the high-speed one. If the larger torque is required also at the high speed, it will be necessary to couple the two sets of coils per phase in parallel at this speed so as to double the flux. This will, however, usually involve an increase in the iron section at the back of the slots, both on the rotor and the stator. When the stator winding is arranged with as many coils per phase as poles (which is unusual in three-phase motors, but general with two-phase ones), it becomes necessary to reverse each alternate *pair* of coils per phase in order to change from the full number of poles to half that number. The change from 12 poles to eight poles mentioned at the end of the question can

Digitized by Google

only be carried out by having two quite independent stator windings—one for each number of poles—arranged either in the same slots or in separate ones.—Q.

Question No. 795.—It is required to transmit overhead 1,000 kw. at a pressure of 50,000 volts for 40 miles. Three-phase alternating current will be used. What is the best method of calculating the sectional area of cable to use? State clearly the losses in the line, and how they are calculated.

Answer to No. 795 (*awarded* 7*s.* 6*d.*).—The problem presented here is similar to one which has been previously discussed in these columns—*i e*, in Question 753, Jan. 27, 1905. The real problem is to design the most economical transmission line operating under the given conditions. Now, in any transmission line we have two factors which bear upon the design of the line. If we have the conductor of a large cross-sectional area, the heating losses will be low, but the capital expenditure will be high. Conversely, if the cross-sectional area of the conductor be small, the heating losses will be high and the capital cost low. It is obvious that we must effect a compromise between these opposing factors. This has been done by Lord Kelvin, who enunciated the law that the total cost of a transmission line and wasted energy per annum is a minimum when the cost of the wasted energy per annum is equal to the interest on and the depreciation of the cable. I have proved this law by the aid of the calculus in the answer which I submitted to Question 753, and therefore I do not think it is necessary to repeat it here.

The current per phase in the transmission line $= \frac{1,000 \times 1,000}{50,000 \times \sqrt{3}} = 11{\cdot}6$ amperes. This, of course, is very small, and it is obvious that the cross-sectional area of the conductor will be small. Let A be the cross-sectional area of the cable in square inches. We can now obtain the resistance of the cable, R, in terms of A. We know that $R = K\frac{L}{A}$, where L = the length of the cable in inches, and K = the specific resistance of copper (assuming copper to be the conductor used) in microhms per cubic inch; K can be taken as $\cdot 66 \times 10^{-6}$ ohms.

I would, however, point out that the current is an alternating one, and the well-known skin effect of the alternating current might enter in if the conductors were thick ones or if the frequency (which is not mentioned) were high. This, of course, would have the effect of increasing K and R. As neither of the two above conditions have any prospect of being fulfilled, we may safely take K at the value given.

$$\therefore R = \frac{\cdot 66}{10^6} \times \frac{40 \times 1,760 \times 36}{A} = \frac{1{\cdot}673}{A} \text{ ohms.}$$

Now, the watts wasted in heating W are given by $W = C^2 R$, where C is the current in amperes.

$$W = \frac{(11{\cdot}6)^2 \times 1{\cdot}673}{A} = \frac{225{\cdot}12}{A}.$$

This is, of course, the waste of energy by heating per phase, and we shall obtain the total by multiplying by 3—*i e*, $\frac{675{\cdot}4}{A}$ watts.

The cost of the waste of energy has now to be determined. We do not know anything about the cost of the power generated. Only a small amount, 1,000 kw., is being transmitted; this may or may not be the whole of the power generated. However, we will take the price of the power as ·5d. per unit. Therefore, the cost of the waste of energy per hour

$$= \frac{675{\cdot}4 \times \cdot 5}{A \times 1,000} = \frac{\cdot 3377}{A} \text{ £,}$$

and the cost per year

$$= \frac{\cdot 3377 \times 168 \times 52}{A \times 240} \text{ £} = \frac{12{\cdot}3}{A} \text{ £.}$$

Now we have the cost of the energy wasted per year we have to obtain the capital cost of the line. Overhead lines, especially in this country, are in their infancy, and very little practical data as regards their cost are available. It must be remembered that the cost of the copper in an overhead line of this description is only a small proportion—may be 10 per cent.—of the total cost of the line, the numerous poles, both ordinary and corner poles, and the insulators taking a large amount of capital. The most recent data on this subject are given in a paper on "The Value of Overhead Mains for Electrical Distribution," by Mr. G. L. Addenbrooke, read before the Institution of Electrical Engineers on Feb. 9, 1905. In this paper is included a table giving the capital cost of a complete transmission line at different voltages. It is found that the cost of the line increases only very slightly with the voltage, which increase is probably due to the increase in size of the insulators and height of the poles. Table A gives particulars of four standard conductors, the capital cost of the transmission line at 50,000 volts. These capital costs are based on those given by Mr. Addenbrooke, and which I may say are not theoretical costs, but are the results of tenders for high-class work. The interest on the capital cost and depreciation, which are taken as 8 per cent. of the total capital cost, are shown, and also the cost of the waste of energy.

TABLE A.

Number and size of cables.	Number, and section of cables in square inches.	Cost of line per mile at 50,000 volts.	Total cost of 40 miles.	Interest and depreciation per annum.	Cost of waste of energy per year given by formula £ $\frac{12{\cdot}3}{A}$.
3	3	£	£	£	£
$^7/_{18}$	·01292	300	12,000	960	945
$^7/_{16}$	·02299	340	13,600	1,088	470
$^7/_{14}$	·03588	390	15 600	1,248	435
$^{19}/_{16}$	·06247	490	19,600	1,568	313

Now, as I have said before, we must choose the cable according to Lord Kelvin's rule. It will be seen that the first cable in the table satisfies the rule nearest—*i e.*, the interest and depreciation per annum equal the cost of waste of energy per annum. In the case of the first cable the equality is very close, indeed, and, therefore, we must choose this cable—*i e.*, three cables of $^7/_{18}$ each—as the one for our transmission line. Of course, we must choose a standard gauge.

As regards the second part of the question, which asks for the losses in the line and their calculation, the chief and only losses of any magnitude are, of course, heating losses. There may be a small amount of leakage, which, of course, will be larger in wet weather. We can easily calculate the heating losses from the formula we have obtained—*i e.*,

$$W = \frac{3 \times 225{\cdot}12}{A} = \frac{225{\cdot}12 \times 3}{\cdot 01292}$$

$$= 52{,}200 \text{ watts.}$$

$$= 52{\cdot}2 \text{ kw.}$$

This is 5 22 per cent. of the total energy (1,000 kw.) transmitted.—ERNEST P. HOLLIS.

Answer to No. 795 (*awarded* 7*s.* 6*d.*).—The quantity that fixes the sectional area of the conductors in a transmission scheme is the amount of power that may be lost in the line. By increasing the sectional area of the conductors we increase the weight of copper employed, but at the same time we decrease the line losses. To find the amount of the line losses that will give a minimum yearly cost, we proceed as follows:

Let T = hours per year during which power is supplied;

x_1 = cost per watt-hour at generating station (pence);
W = line losses;
W_1 = power output from station;
W_2 = power supplied at end of line;
V_1 = voltage at generator end;
V_2 = voltage at receiving end;
C = current in each lead;
q = sectional area of each lead;
R = resistance of each lead;
L = length of transmission;
ρ = specific resistance of copper.

It is found that the cost per mile of installing a transmission line is approximately a linear function of the

Digitized by Google

sectional—*i.e.*, cost = $(a + b\,q)\,L$, where a and b are constants obtained by plotting values for the particular type of construction to be employed. If we allow p per cent. on this principal for interest, depreciation, and upkeep, we have the yearly cost of the line = $(a + b\,q)\,L\,p$. The yearly cost of the line losses will be $W\,T\,x_1$. Hence the total yearly cost of transmission in pence will be $W\,T\,x_1 + (a + b\,q)\,L\,p$.

$$\text{But} \quad W = \frac{C^2 \times 2\,L\,\rho}{q} \quad \text{and} \quad C = \frac{W_1}{V_1} = \frac{W_2 + W}{V_1}.$$

$$\therefore\ q = \frac{(W_2 + W)^2}{V_1^2} \times \frac{2\,L\,\rho}{W}.$$

That is, total yearly cost

$$= T\,x_1\,W + a\,L\,p + 2\,b\,L^2\,p\,\rho\,\frac{(W_2 + W)^2}{W\,V_1^2} = K.$$

Differentiating and equating to zero to find the minimum value of K we get

$$0 = T\,x_1 + 2\,b\,L^2\,p\,\rho\left[\frac{V_1^2\,W2\,(W_2 + W) - (W_2 - W)^2\,V_1^2}{(W\,V_1^2)^2}\right]$$

$$T\,x_1 = -\frac{2\,b\,L^2\,p\,\rho\,W_2^2}{V_1^2\,W^2} - \frac{2\,b\,L^2\,\rho\,p}{V_1^2}$$

whence

$$T\,x_1 = \frac{2\,b\,L^2\,p\,\rho}{V_1^2}\left[\frac{W_2^2}{W_2} - 1\right]$$

$$\therefore\ \frac{T\,x_1\,V_1^2}{2\,b\,L^2\,p\,\rho} + 1 = \frac{W_2^2}{W^2} \quad \therefore\ W = W_2\sqrt{\frac{2\,b\,L^2\,p\,\rho}{2\,L^2\,b\,p\,\rho + T\,x_1\,V_1^2}}.$$

Using this equation we can find the value of the line losses that will give us a minimum yearly cost of transmission. As in the question sufficient data are not given to determine W, we must assume a value to complete the calculation; let W = 5 per cent. of the total power transmitted.

To find the power lost in a three-phase system we proceed as follows: We have power output of line = $C\,V_2\,\sqrt{3}\cos\phi$ watts. As no power factor is stated, we will assume an arbitary value, say ·9. Then in this case

$$C \times 50{,}000 \times 1{\cdot}73 \times {\cdot}9 = 1{,}000 \times 1{,}000,$$

whence

$$C = 12{\cdot}8 \text{ amperes.}$$

Then loss in one lead = $C^2\,R$, but $R = \frac{L\,\rho}{q}$ Hence loss in one lead

$$= \frac{C^2\,L\,\rho}{q} = \frac{12{\cdot}8 \times 12{\cdot}8 \times 40 \times 5{,}280 \times 12 \times {\cdot}00000066}{q}$$

$$= \frac{50 \times 1{,}000}{3},$$

whence

$$q = {\cdot}0165 \text{ square inch.}$$

No. 9 S.W.G. has a sectional area ·01629, which would probably do.—H. E. H.

Answer to No. 795 (*awarded* 7*s.* 6*d.*).—Several factors have to be considered in the calculation of overhead transmission lines, the most important of which are the pressure loss and the financial point of view. If the conductors are small the cost of copper will be small, but the loss of power due to the heating of the wires will be great. The reverse will take place with large conductors. There is a *most economical conductor* for which the sum of the annual cost of generating the lost energy and the charge of interest and depreciation on the copper is a medium. However, it frequently happens, in polyphase systems especially, that the most economical conductor would give too great a pressure loss, and the size of the wire is then determined by this last factor. The usual pressure losses are: for light, 2 to 4 per cent., and more; for power, 5 to 7 per cent, and more. In this particular case it seems as though the most economical conductor would give a moderate pressure loss, as will be shown later.

If we call R the resistance of one conductor in ohms, C the current in each conductor in amperes, the *pressure loss* in volts will be 2 C R. For hard-drawn copper, the resistance in ohms at 60deg. F. will be

$$R = {\cdot}04317 \times \frac{\text{length in miles}}{\text{area in square inches}}$$

So that

$$\text{pressure loss} = {\cdot}08634\,\frac{C \times L}{A},$$

or,

$$A = {\cdot}08634\,\frac{C \times L}{\text{pressure loss}}.$$

This equation will give us the section of the wire if we assume the pressure loss. In our case L = 40, and if we suppose the power factor to be 1, C = 11·55 amperes.

The *energy loss* in the three wires will be in watts 3 C^2 R.

The relation between pressure loss and energy loss is: energy loss = 1·5 × C × pressure loss.

Table B gives the cross-sectional area of each conductor, the energy loss, and approximate weight of copper for different pressure losses, worked out for this particular case. The losses are given in per cent. of the total voltage and output.

TABLE B.

Pressure loss. Per cent.	Energy loss. Per cent.	Cross-section. Square inches.	Weight of copper in tons.
1	·87	·07980	87·1
2	1·74	·03990	43·6
3	2·60	·02660	29·0
4	3 47	·01995	21·8
5	4·33	·01596	17·4
6	5·20	·01330	14·5
7	6·06	·01140	12·4
8	6·93	·00998	10·9
9	7 80	·00887	9·7
10	8·66	·00798	8·7

Financial Considerations.—It is difficult to determine the most economical conductor with accuracy, as it depends on many factors which cannot be known exactly before the undertaking has been running for some time, such as the cost of generating one unit, the load factor, etc. Each case must be dealt with separately, according to circumstances. The output is proportional to the current, and the lost energy to the square of the current. It follows, therefore, that the lost energy will be proportional to the square of the load factor. With an energy loss of 5 per cent., for instance (50 kw. in our case), the total number of Board of Trade units lost per year would be: 8,760 × 50 = 438,000 kilowatt-hours if the full load was maintained without intermission. If we assume an average annual load factor of 30 per cent., this number will be reduced to 438,000 × ·09 = 39,420 kilowatt-hours.

Let us further assume that the cost of generating one unit is 1d., the interest and depreciation on copper 10 per cent., and its price £65 per ton. We obtain the result in Table C.

TABLE C.

Energy loss. Per cent.	Annual cost of lost energy. £	Annual cost of copper. £	Total. £
·87	28	566	594
1·74	57	283	340
2·60	85	188	273
3 47	114	142	256
4·33	143	113	256
5·20	171	94	265
6·06	199	81	280
6 93	228	71	299
7 80	256	63	319
8·96	285	57	342

With the above assumptions it will be seen that the total cost is practically constant, and a minimum for pressure losses of 4 to 6 per cent., so that the most economical conductor would be quite compatible with a moderate pressure loss.

Other Losses of Energy.—At such a high voltage as 50,000 volts a silent discharge will take place between the wires, and unless these are placed very far apart, the loss due to this fact may become important. There will also be some leakage over the insulators, specially in wet weather. These losses are independent of the size of wire used, but as the pressure drop will be increased by them they might have to be taken into account in determining the cross-sectional area.—ALTERNATOR.

Answer to No. 795 (*awarded* 5*s.*).—The best section of conductor is the one which, taking everything into account, will give the best results financially, this test being the

Digitized by Google

ultimate one for the solution of all engineering problems. In the above case, since the power to be transmitted is a fixed quantity, the revenue is also presumably a constant, so that the best section is that on which the total average annual expenditure is least.

The annual expenditure can be divided into two main sections: (1) the amount paid in interest on capital, repairs, depreciation; and (2) the cost of the energy wasted in the conductor; and we can prove mathematically that when costs under heading (1) equal those under (2) the total is a minimum. Under heading (1) the capital expenditure depends entirely on the weight of copper, since the small differences in section permissible would not affect the size of insulators, posts, or labour, and as long as the section is a reasonable one depreciation and repairs will also be constant for a given weight of copper. Hence the weight of copper is the only variable. Under heading (2) the loss in the line depending on the sectional area ($C^2 R$) is all that is practically affected by any variation in its size, but, of course, the generating plant is involved, since if the line loss were unduly large the capacity of the generating plant would have to be increased to give the same power at the far end, thus requiring extra capital at the station, extra labour, extra repairs, etc. The simplest and fairest way to deal with this is to find or estimate the *total* cost of a unit to the producer and charge the energy wasted in the line at this rate.

Before the annual energy loss can be even approximated it is necessary to assume a load factor, and, of course, to do this moderately accurately a knowledge of the local conditions such as number and nature of the probable consumers. It will be seen from the above that a number of points in each individual case must be carefully considered before any calculations can be done. To show the methods the following figures and assumptions are given. Power to be transmitted = 1,000 kw.; voltage (assumed at distant end of line), 50,000 volts virtual; power factor (dependent on plant installed), assumed, 80 per cent. Let C = amperes required

$$= \frac{1{,}000 \times 1{,}000}{50{,}000 \times \sqrt{3}} \times \frac{100}{80} = 14\,5 \text{ virtual amperes.}$$

Now take a trial section of wire, say No. 9 S.W.G., = ·0163 square inch. Let R = resistance of 40 miles. (tables)

$$= 1{\cdot}502 \times 40 \times \frac{1{,}760}{1{,}000} = 106 \text{ ohms approximately.}$$

Loss in the line $= 3\ C^2 R = 3 \times 14{\cdot}5^2 \times 106 = 67{,}000$ watts.

Assume load factor 25 per cent. Units wasted per annum

$$= 67 \times 24 \times 365 \times \frac{25}{100} = 144{,}000 \text{ approximately.}$$

Assume cost of unit = ·75d. Annual loss heading (2)

$$= \frac{144{,}000}{240} \times {\cdot}75 = £450.$$

Weight of 120 miles of No. 9 S.W.G.

$$= 188 \times 120 \times \frac{1{,}760}{1{,}000} = 39{,}800 \text{lb.}$$

Take cost of copper at 10d. per lb. Capital expended on copper

$$= 144{,}000 \times \frac{10}{240} = £1{,}650.$$

Assume that interest, depreciation, and repairs on copper = 10 per cent. per annum. Costs under heading (1)

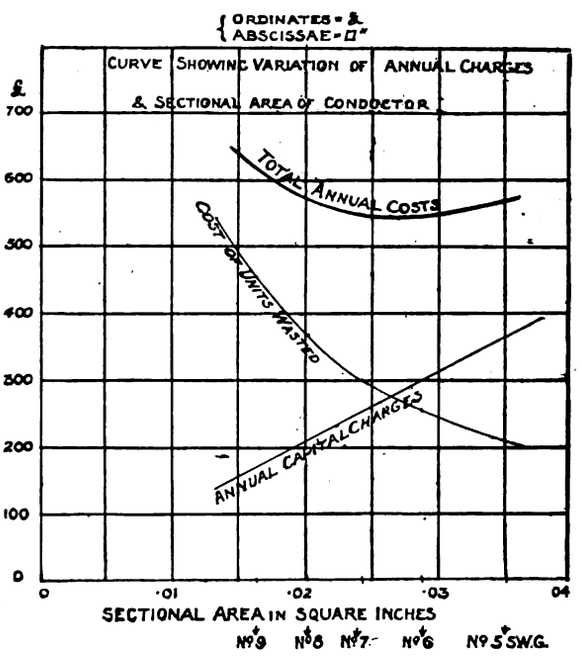
$$= 1{,}650 \times \frac{10}{100} = £165.$$

We see, therefore, that loss under head (2) is much larger than that under (1), so that the sectional area is too small.

On trying another size, No. 6 S.W.G. = ·0289 square inch, the costs work out: heading (1) £292, and heading (2) £252. In this case the total cost per annum only = £544, against £165 + 450 = £615 in the former case.

The curves given show very clearly how the costs vary. The capital charges follow a straight line law within limits being proportional to the area, while the power costs follow a curve proportional to the resistance which is proportional to $\frac{1}{\text{area}}$.

In the above examples the voltage at the distant end has been assumed 50,000 volts, so that at the station it must



be higher. Supposing No. 8 S.W.G. to be chosen (this would give a margin for extensions), the total loss in the line is

$$3\ C^2 R = 3 \times 14{\cdot}5^2 \times 59{\cdot}5 = 24{\cdot}9 \text{ kw.}$$

$$\text{This} = \frac{24{\cdot}9 \times 100}{1{,}000} = \text{say } 2{\cdot}5 \text{ per cent. of output.}$$

The lost volts $= C R \sqrt{3} = 14{\cdot}5 \times 59{\cdot}5 \times \sqrt{3} = 1{,}490$, so that the generating end volts must be about 51,500. The capacity current has been covered by the assumption of a power factor, and will depend on the distance the wires are apart, etc.

It will be seen that the best section has a density of only about 500 amperes per square inch, but that a fairly wide variation from this can be made without very seriously affecting the economical working. If the voltage had been 50,000 at the generating end, then the current would have been slightly increased and the losses a little greater, each area would have a slightly different sized current, which could be easily approximated within ½ per cent., and since so many assumptions must be made it is useless to work too accurately. All the necessary calculations can be worked on a 5in. slide rule.—NEWCASTLE.

[Other replies to Question No. 795 will be given in our next issue.—ED. *E. E.*]

Rain and Speed.—A gentleman has been writing to the Press opining that when the horse-drawn conveyance has been entirely superseded by the motor we shall still be without any quicker means of locomotion as soon as the roads become wet. He asks: "Now that the motor has arrived are we not faced with a new traffic problem, associated with new dangers? I refer to the peril of the slide-slip when the wood or asphalt are 'slithery.' After yesterday's rain I noticed that the motor 'buses seemed to be running much slower than usual—in fact, little or no faster than horse-drawn vehicles." This is where the vehicles running on rails comes in. On a slippery road the motor 'bus has to proceed somewhat gingerly, while the electric car remains comparatively unaffected. It is true that rain occasionally exerts the opposite effect, and results in an undue acceleration upon declines, causing the car now and then to become derailed, but improved braking appliances have reduced this risk to a minimum.

Supplement to "The Electrical Engineer,"
AUGUST 11, 1905.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

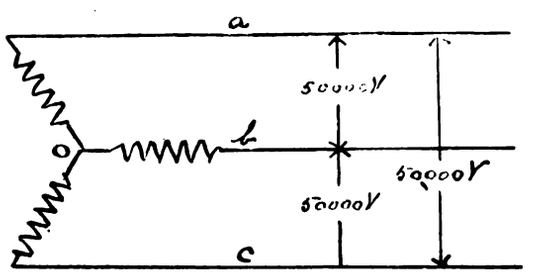
802. Two rotary converters (three phase) are running in parallel on alternate-current side. They are connected on direct-current side with only positive of one and negative of the other closed. Explain how it is possible for a load to be taken off direct-current bus bars.—A. G. H.

803. A Parsons two-phase alternator, 25 kw., is excited from a small exciter carried on an extension of the main shaft. The alternator field is connected directly across the exciter brushes through a Weston type of ammeter placed on the switchboard. There is a switch and regulating resistance in the exciter field. When the machine was started up, the current was in, say, the positive direction round the alternator field, as shown by the ammeter, which read properly. When the exciter field switch was opened and closed again, the current round the alternator field was reversed, as shown by the ammeter reading the wrong way. On testing it was found that every time the exciter switch was opened the current round the alternator field was reversed, the ammeter reading first right, then wrong, and so on apparently indefinitely. What is the cause of this?—TURBO.

ANSWERS.

Question No. 795.—It is required to transmit overhead 1,000 kw. at a pressure of 50 000 volts for 40 miles. Three-phase alternating current will be used. What is the best method of calculating the sectional area of cable to use? State clearly the losses in the line, and how they are calculated.

Answer to No. 795 (*awarded* 5*s.*).—Suppose the system to be star connected, as in sketch, and that *a*, *b*, and *c*



represent the line wires. The voltage between any of the line wires and the neutral point, 0, will be $50{,}000/\sqrt{3}$; if, then, the combination is in a balanced condition, such as would be the case when supplying nothing but motors, the current, C, in any one of these three lines may be obtained from

$$C \times \frac{50{,}000}{\sqrt{3}} = \frac{1{,}000{,}000}{3}$$

$$\therefore C = \frac{1{,}000{,}000}{3} \times \frac{\sqrt{3}}{50{,}000}$$

$$= \frac{20\sqrt{3}}{3} = 11{\cdot}546, \text{ say 12 amperes.}$$

At 1,000 amperes per square inch this would mean a No. 10 gauge wire, but although the wire would be large enough for this current, the loss might, perhaps, be too great. The drop between generator and end of line would be 3,200 volts (approx.). Suppose a No. 3 S.W.G. was employed for the lines, this has a resistance of about ·49 ohm per 1,000 yards. The drop would then be

$$\frac{40 \times 2 \times 1{,}760}{1{,}000} \times \frac{49}{100} \times 12 = 828 \text{ volts (approx.)}$$

As to which size cable for the line would be most suitable, this must be decided by a reference to Kelvin's law. Much would depend on the cost of generation, local conditions, etc. There is a point with regard to the employment of a larger size wire, and that is, that, other things being equal, the losses by atmospheric discharge will be less as the diameter of the wire is increased. Losses due to this discharge are considered to vary directly as the potential, and with such a voltage as 50,000 this would be by no means a small matter. With such a high potential it would be necessary to keep the line wires about 10ft. apart. Good quality of insulators about 12in. in diameter would be required. There is also the permission to be obtained to erect such a line, wayleaves, etc. to be secured. In similar cases, instead of ordinary wooden poles, it has been found advisable to employ steel supports. By suitably running the lines so that, while still the normal distance apart, they formed a sort of cable, mutual induction would be considerably reduced. So far all is fairly easy, but we have yet to tackle a most difficult problem—viz., the effects of capacity and inductance—and not only these phenomena as regards the line itself, but also the various pieces of apparatus the system has to supply with electrical energy. The idle current in the lines must be allowed for, and at the best this idle current can only be approximately calculated. The periodicity of the supply is not stated in the question, and this is a factor to be reckoned with. The charging current will increase with the periodicity; also the higher the periodicity the greater the drop due to impedance. For a complete treatment of this question the querist should study some of the advanced works on the subject, but the whole matter is one little understood and of extreme difficulty.—M. M.

Question No. 796.—Is it necessary to clean the tubes of the superheaters of Babcock water-tube boilers? If so, what is the best method of doing so, and how long may such superheaters be run without cleaning?

Answer to No. 796 (*awarded* 7*s.* 6*d.*).—Internal cleaning of the superheater tubes of Babcock boilers is, so far as the writer's personal experience goes, not necessary. An installation of 12 Babcock boilers with superheaters—the evaporation totalling 200,000lb. per hour at a temperature of 580deg. F.—has been working for over four years, and recent examination shows very little incrustation in the tubes. From each of four superheaters a tube was taken and cut at the bend; the deposit was in no case measurable, although the water used in the boilers was far from good. Deposits from steam would naturally be negligible, and it is the water used in flooding the superheaters that causes what scale is found. As, however, this water is drawn from the steam and water drum of the boiler, it is, perforce, free from most of its scale-forming constituents; being heated to temperatures of the order of 350deg. to 385deg. F., incrustation is thus but slow. The tubes being small, the steam velocity is high, and the superheater, not being subject to the direct impact of the flames, is maintained at a fairly uniform temperature; there is thus little predisposition to deposit at particular points. Probably by the time incrustation serious enough to call for attention results, it would be wiser economy to replace the tubes altogether. The smallness of the tubes, 1½in. diameter, and the U bend will render cleaning thoroughly a costly matter, and it will probably be cheaper to replace the tubes. The manifolds and ends of the tubes should be examined regularly, and it is advisable to, if deposit be suspected, to take out a tube and cut it at the bend. Externally the tubes should be freed from dust, and this is done by the use of steam jets directed through the openings left in the settings for the purpose. Once a week for this operation should suffice.—S. E. T.

Answer to No. 796 (*awarded* 7*s.* 6*d.*).—The greater part of the steam generated in a Babcock boiler comes up the front headers, comparatively little being generated in the drum. The tee pieces, A A (Fig. 1), which form the head of the down pipes to the superheater, are near the back end of drum. This causes the steam to flow some distance before entering the tee pieces, therefore very little wet steam or solid matter is carried down into the superheater. This being the case, it is practically unnecessary to clean the tubes of the superheater or superheater boxes, although, of course, it is advisable to examine them periodically, say once every four months. Fig. 1 is a diagram of the pipes connecting the superheater to the boiler, looking at the boiler from the back end. I remember coming in contact with the following case: The valves connecting the superheater uptakes and the saturated steam outlet to the steam range were both left open in order to reduce the temperature of the superheated steam. The flooding and draining cock was also partly open to flood. The result was that some of the water from the bottom of the drum flowed down the pipe, B, and up C into the superheater bottom box, and the superheater acted partly as a boiler in parallel with the main tubes and drum.

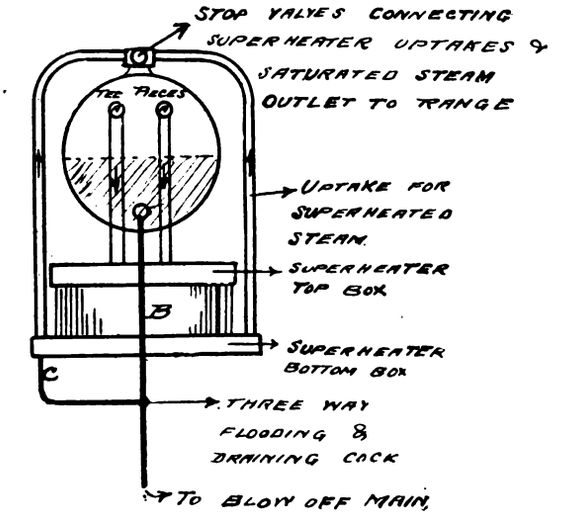

FIG. 1.

Under these conditions and with bad water the superheater bottom box and ends of the tubes were soon choked up: therefore the circulation was stopped, and superheater tubes became red hot and burnt away, and new superheater had to be fitted. Particular care should be taken to blow down thoroughly before putting boiler on range; also keep three-way flooding and draining cock in good repair.—SUPERHEAT.

Answer to No. 796 (*awarded* 5*s.*).—The *exterior* of the tubes of Babcock and Wilcox superheaters should, of course, be cleaned when the boiler is laid off for the periodical cleaning. The writer has never found, during many years' experience of this type of boiler, any necessity for cleaning the interior of the superheater tubes. If the water used be impregnated with much scale-forming matter, and the boiler is only steamed intermittently, and the superheater "flooded" each time the fires are banked (or if the boiler be allowed to stand with slow fires in for long periods), then it would be possible for scale to be formed on the inside of the tubes, as, when steam is being raised, the superheater becomes, in fact, part of the boiler heating surface. It is not a wise plan to fill the boiler with cold water, especially if containing much scale-forming matter when standing at little or no pressure. There is one point in connection with the working of Babcock and Wilcox superheaters—namely, the draining of same before opening boiler to range. It is always advisable to make quite sure that all water is cleared before closing the drain cock—the writer considers the class of cock provided with sight-glass by far the best of the several patterns in use—as any loose sediment, etc., which may be present in the tubes is thus blown out during the draining operation, also the risk of passing water over to range, with its attendant dangers, is minimised by spending half a minute or so longer over the operation. The interior of the superheater manifolds, particularly round the tube joints, should be carefully examined when the boiler is laid off for cleaning. At a large station in the Midlands with which the writer was connected, it was held a strict rule that no boiler superheater (B. and W.) was to be "flooded" unless intended to be shut off the range for not less than 24 hours. In addition, steam was to be passed through the superheater even when the engine-room plant was standing. To effect this a steam-pump would usually be run to fill up a water-storage tank. A special tool, similar to the turbine type, would be necessary for cleaning the interior of B. and W. superheater tubes. This tube cleaner consists of a turbine operated by water power, or air pressure, which works in ball bearings, and to which is attached four arms having steel cutter wheels at their extremities. The water which passes through the turbine has the effect of washing out the tubes.—S. L.

Answer to No. 796 (*awarded* 5*s.*).—It is not usual to clean out the superheater tubes of a Babcock boiler, but this can be done by removing the caps on the header end of the tubes, when you can use a wire brush from the top and bottom headers. Scale is not likely to form on these tubes if your boiler feed water is free from impurities; if this is not the case, it can be treated before entering the boiler. It would have to be in a fairly bad state, however, to affect the tubes, since the tubes are only flooded before getting up steam and drained as soon as the boiler is put on the range. The cock which floods these tubes is taken from the lower half of the boiler, so that impurities which might collect on the surface do not enter the tubes. The writer has been in some four stations using Babcock boilers, and has never had the slightest trouble with the superheaters extending over a period of four years. In some instances these tubes are regularly examined when the boiler is down for cleaning. The method of draining the superheater should remove any loose scale that may form inside the tubes, and even if you use the air-pump discharge water, which may contain oil, this would not interfere with these tubes, as the oil would rise to the surface when the boiler is at rest. The trouble is caused by the circulation of the water in the boiler at high temperatures when at work. The best plan for ascertaining if scale is forming is to remove one of the caps, when this can easily be judged.—W. F. S.

Answer to No. 796 (*awarded* 5*s*).—Considering the fact that in superheated steam there is no water or water vapour, it is not difficult to see that the same actions of corrosion and incrustation of foreign matter in the water on the shell and tubes of the boiler will not occur in the tubes of the superheater. There is, however, just the possibility that the steam as it leaves the boiler, before reaching the superheater, is not *dry saturated* steam, but that it contains a percentage of moisture. Then, of course, water is carried into superheater entrance, and with the water there is probably some of the impurity of the water as originally fed to the boiler. This would lead to a mild incrustation on the inside of the entrance tubes of the superheater, but it would not make very great progress in development. Where pure or purified feed water is used this tendency is diminished considerably. There is, therefore, no necessity whatever, except in extreme and exceptional cases, to clean the tubes of the superheater after the manner in which the tubes of the boiler are cleaned. But, as is the case with every good machine, unless there is a periodical inspection of the internal and external surfaces of the tubes of the superheater, the superheater is liable to become a little erratic at times. The inspection should be made about five times a year, whilst the cleaning will probably not be required more than once a year. All that need be done in the way of cleaning is scraping. Attention should be paid to the fact that the condition of one or two tubes does not afford a reliable criterion of the remainder, therefore *each* separate tube should be inspected. As well as the above, superheaters should, as a general rule, be tested hydraulically at intervals of two or three years, the object of such tests being to find out any mechanical weaknesses in the tubes themselves or their fastenings.—G. W. BURLEY.

Question No. 797.—With gas at 2s. 6d. per 1,000 cubic feet and electricity at 1½d. per unit, can the electric arc system show an advantage for street-lighting over the high-pressure gas system in (*a*) initial outlay, (*b*) running costs, (*c*) distribution of light?

Answer to No. 797 (*awarded* 10s.).—There are few questions in connection with lighting round which so much controversy has raged as that of gas *versus* electricity for street illumination. When we come to consider the photometric values of the two systems we meet with great difficulties; for instance, where should we find two individuals who would agree as to the candle-power of an arc lamp; and then again, given that the electric arc far outshines its rival, there are many who object to the cold glare and deep shadows of the arc lamp. Let us consider the points as formulated in the query.

(*a*) The initial outlay will be but little different in either case. The ground has to be opened up for pipes as well as for cables, and the cost of the cables themselves will just about balance that of the piping. With regard to posts, lanterns, and lamps, electricity will undoubtedly exceed the cost of gas, although if the gas lamps are of anything like the light-giving power of the arcs, and are mounted on high ornamental columns with good lanterns, the difference will not be so great as might be supposed.

(*b*) If we consider each system per candle-power, the electric arc has a great advantage. A fair average estimate is that an expenditure of 500 watts of electrical energy will give 1,000 c.p.; for such a light with gas we should require about 100 cubic feet per hour. On the basis of 2s. 6d. per 1,000 cubic feet this would mean 3d. per hour, and with electrical energy at 1½d. per unit ·75d. per hour for a lamp giving 1,000 c.p. It must be remembered, however, that the arc will keep its brilliancy unimpaired, while the mantles rapidly fall off in efficiency; therefore, although the arcs will cost more for attendance, carbons, etc., if the gas mantles are kept in good condition no small outlay will be necessary on that account. The running cost per candle-power will be very much less in the case of electricity, but if the running cost per lamp is the basis of calculation, no doubt gas will have the advantage. In several places known to the writer the mantles require changing much more frequently than is the case. Thus we may have the running cost kept down, but at the price of a lowered efficiency.

(*c*) Distribution is a point where the arc lamp is somewhat at a disadvantage. While for main thoroughfares it is pre-eminently suitable, for the general lighting of side streets it can hardly be deemed satisfactory. The arc light is too concentrated for this purpose, and the gas mantle has an advantage over the arc for detailed distribution. Where street-lighting by electricity is in vogue, the Nernst lamp has been found to give satisfaction for side-street work, and now the tantalum lamp running at two watts per candle-power will put a new weapon in the hands of the electrical engineer. For distribution in large open spaces or main roads the elevated electric arc lights its surroundings with a well-diffused illumination unapproached by any gas lamp on the market. That this is a fact is pretty evident from the various powerful gas lamps that have been placed on the market during the last few years. Imitation is the most sincere form of flattery.

Generally, at the prices quoted, electricity should be able to more than hold its own against gas, but, in order to obtain the appreciation it deserves, every care is necessary in its installation. The idea of ground globes for diffusion of the light, so much the fashion some years ago, has not met with general public approval. Clear globes are better appreciated. The average man in the street likes to see the light itself; he is, as a rule, not so much concerned with the illumination. There is also another point that may have to be considered. If a station engineer were to erect arc lamps in one street, inhabitants of less favoured thoroughfares might feel aggrieved. It may be safely affirmed that having once enjoyed the electric light as a street illuminant, the average individual would hardly care to return to gas lighting.—M. M.

Question No 798.—A short-circuit occurred across two of the terminals of a 50-h.p. three-phase motor when running at full load. The motor-house is connected to the power-house by an overhead line consisting of three bare copper wires No. 4 S.W.G., placed one above the other, with a spacing of about 10in. between them. The line consists of two short spans, the intermediate support being an iron bracket on the corner of the power-house, which bracket is also situate much higher than the support on the motor-house, this span having an inclination of about 30deg. to the horizontal. Concurrently with the short-circuit on the motor several flashes were seen between the top and middle lines of the motor-house span. The wires were badly burnt and pitted on *both spans*. A distance of several feet, however, on either side of the intermediate support showed no signs of burning. A main 300-ampere fuse in the power-house was blown, while the 120-ampere motor fuse was overheated only. The weather was fine and calm. We have had a similar occurrence before when using a different make of generator, both generators being of the revolving-field type, 330 volts, 42 ~, and of modern construction, motor and generator A wound. Can any of your readers furnish an explanation of the arcing on the line.

Answer to No. 798 (*awarded* 7*s.* 6*d.*).—The arcing, and consequent trouble, is due to the fact that when bare conductors in fairly close proximity to one another are carrying abnormally heavy currents, as in the case under consideration, attractions and repulsions due to electromagnetic action are set up, which cause swinging and may cause actual contact and welding together of the conductors. A very interesting example of a short between two bare conductors, caused by this swinging, and which finally welded the conductors together, is given in the chapter devoted to "testing of mains" in Mr. C. H. Wordingham's "Central Electric Stations." In the case under consideration most of the damage has been done in and about the motor-house, and for the following reasons. The actual short took place in the motor-house, as did also the flashing and arcing. The motor-house will probably be somewhat confined, and will not give the conductors as good an opportunity of getting rid of the heat generated in them due to the passage of heavy currents as the conductors in the neighbourhood of the intermediate support will probably have, which support, besides being in a less confined situation than that in the motor-house, may possibly be subjected to a current of cold air due to draughts.

The sequence of events will probably be as follows: The conductors are stated to be *about* 10in. apart, and it is very likely that in the motor-house they may be (due to sagging or careless putting up) somewhat nearer together. Now, on the short occurring between the two terminals heavy currents will at once flow in the two leads attached to these terminals, with the result as indicated above—viz, that swinging due to electromagnetic attractions and repulsions has taken place, and once or twice the conductors have swung near enough together to just start an arc, which is, however, at once broken by the conductors swinging away again. This accounts for the flashing seen previous to the main 300-ampere fuse blowing, which has been caused by the conductors at last coming so near together that the resistance to the passage of a current between them is so much diminished that still heavier currents are set up, an arc is started, and the main 300-ampere fuse blows. That this fuse blows while the motor fuse is simply overheated seems to point out that the 300-ampere fuse is in circuit with a conductor feeding several other motors, and that the overload caused by the short on this particular motor, together with the other loads, has blown the fuse. It would, therefore, be advisable to somewhat strengthen the main and weaken the motor fuse, thus ensuring that in case of other similar occurrences the motor will be cut out at once, the main fuse remaining intact and the shut down being confined to the one motor. The obvious course to be taken is to at once effectually insulate the two terminals from each other, and thus prevent other similar disasters.—W. T. W.

Answer to No. 798 (*awarded* 7*s* 6*d.*).—The voltage used on the transmission line mentioned in the question being only 330 volts, it is obvious that the phenomena noted cannot be due in any way to any sudden rises of pressure in the system, also the distance apart of the lines—*i e*, 10in.—is much too great to allow any arcing due to the above cause, even had the line pressure been 10 times as high. The real cause of the arcing across the lines is due, in my opinion, to the sagging of the top wire caused by its superheating with the current supplying the short-circuit across the terminals of the motor. The sag has been so great as to bring it into contact with the second wire which

Digitized by Google

is underneath it. It is my purpose to explain why the top wire should sag more than the second wire.

In the first place, it is well known that when a current passes through a wire, the wire is heated according to the law given below.

$$J \cdot H = C^2 R t \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where J = Joule's equivalent;
H = the amount of heat generated;
C = the current strength;
R = the resistance of the wire;
t = the time for which the current passes.

I would ask readers to note particularly that the amount of heat generated varies as the *square* of the current. It is also well known that when a wire is heated it expands in all directions. However, the linear expansion alone concerns us here. The amount of expansion (linear) per inch length is given by the formula

$$L = kT \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where L = the increase in length;
k = the coefficient of expansion;
T = the rise in temperature of the wire.

In Fig. 1, T_1, T_2, and T_3 are intended to represent the terminals of the motor. Their connections to the respective lines are also shown. Now the short-circuit has occurred between T_1 and T_3. From this it will be seen

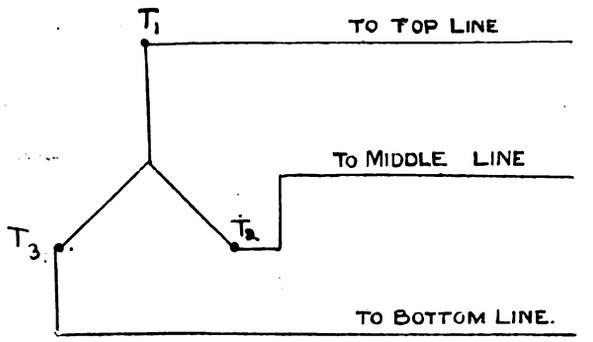

FIG. 1.

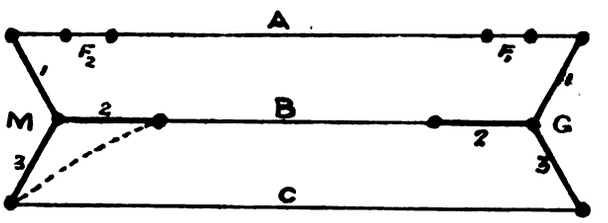
that the system is not now in balance, and there will be a very large current flowing in at T_1 and T_3 in order to supply the short-circuit. Thus the top and bottom lines will be carrying a large current and the middle wire very little. In the question it is stated that the motor fuses are overheated only, the fuses being 120 ampere fuses. Now, of course, the fuse would not blow at a sudden rush of current of the above value, and it is quite possible that the value of the short-circuit current will be greater than this. As I have pointed out, since the heating of the wire varies as the square of the current strength, the increase in temperature of the wire, and, therefore, the lateral expansion, will increase correspondingly.

FIG. 2.

In Fig. 2 I have shown a diagram of the wires. The full line shows the normal position of the wires. There will, of course, be a slight sag due to their own weight. This I have not shown. The broken lines indicate the position taken up by the wires during the short-circuit. The inclination of the wires would cause the point of maximum sag to be very near to the lowest point in the wires. The procedure has probably been as follows: The short-circuit has occurred at the terminals of the motor, causing, for the reasons explained, the top and bottom wires to sag very much and the middle wire very little. The current has probably been one of about 120 amperes, and may have been on for rather a long time, or may have been a larger one for a short interval. Anyhow, the current has heated the wires to such an extent that the top one has come into contact with the middle one. The arc has run along the wires, and apparently has not had time to run along to the intermediate support, or it has burnt out before it has got there. This current has been large enough to blow the 600-ampere fuse in the power station. I think that the above probably represents what has occurred in the question.—ERNEST P. HOLLIS

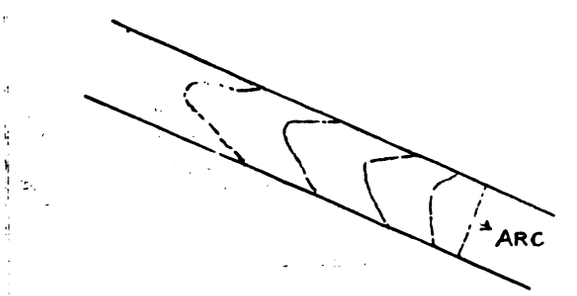
Answer to No. 798 (*awarded* 7*s.* 6*d.*).—There are several probable causes of the arcing or flashing referred to in the



above question, but the writer will only touch upon what he regards as being the cause of it. In the accompanying figure we have a diagrammatic representation of the circuit. G is the star-wound generator, M is the motor, and A, B, and C are the three mains from the generator to the motor. Under ordinary circumstances the currents in A, B, and C are practically equal and of normal value. But suppose that the terminals of the windings 2 and 3 of the motor are connected together so as to produce the condition of short-circuit referred to in the question. Then abnormal currents will traverse the conductors B and C, currents of approximately the same value, and these will traverse the windings 2 and 3 of the generator. This will result in the immediate propagation of a magnetic flux of an enormous value through the windings of the remaining limb of the star. This magnetic flux will be alternating in character, and, hence, it will set up an induced E M F. in the winding 1 of the generator. The magnitude of this E M F. will be many times greater than the normal E M F. of supply; it is, in fact, sufficient to break down the insulation of the large air-space between the two conductors, A and B, and to cause a spark to pass from one conductor to the other.

The explanation of the peculiarity of the larger fuse—*i e*, the 300-ampere fuse—blowing, whilst the smaller fuse was only overheated, appears to the writer to be as follows: Although a greater current has evidently been caused to traverse the coils 1 of the generator and also the wire A, yet all the current has not passed from end to end of A, but some of it has taken a short path—viz, that of the spark or arc. Since, however, the smaller fuse is overheated, it follows that the current through it has been increased, but not to the same extent that the current through the larger fuse has been increased, and certainly not sufficiently to blow it.—G. W. BURLEY.

Answer to No. 798 (*awarded* 5*s.*).—Immediately after the short on the 50-h.p. motor, the voltage of the line would rise and flash across from one wire to the other.



This arcing due to the inclination of the line would gradually rise and run along in an arched form, the wires acting as horns, until it got too long to maintain itself, and so would break, as shown in the figure. Due to this arc, or second short, the voltage would rise and the same arcing occur again, and so on until the main fuse blew. In the case I have in mind no less than seven distinct shorts were observed on the generator meters.—H. E. T.

Supplement to "The Electrical Engineer,"
AUGUST 18, 1905.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

804. I am employed at a paper mill, and frequently receive complaints from the printers about electricity being in the paper. I have tried several experiments with it, but without success. What is the best method of reducing or preventing the effects complained of?—J. W.

805. Show by comparative figures the advantage of using laminated poles compared with solid ones for direct-current machines. Is there any real gain in the use of the former, when air-gap is not less than half the width of slot?—A. G. S.

806. At a power station they use several alternating arc lamps, B.T.H. enclosed type in parallel on a 220-volt circuit, with a choking coil in series. The carbons used are not consumed equally unless one of them is cored and the other solid. What is the reason they do not burn in equal quantities?—H. W. C.

807. In a continuous-current central station it is believed a consumer is using his current to earth. Describe the best method of detecting and locating this consumer.—H. W. N.

ANSWERS.

Question No. 799.—An electrostatic voltmeter is continually giving trouble through the metal parts corroding. What is the reason of this?

Best Answer to No. 799 (*awarded* 10*s.*).—Several electrostatic voltmeters under my care used to give considerable trouble, owing to the corrosion of metal parts, until I discovered the cause of it. A Kelvin electrostatic voltmeter for reading extra high pressure is shown in Fig. 1. The high-pressure terminal 1 is connected through a water fuse to A-phase 'bus bar. Metal cages 3 and 4, completely encased in mica and connected together by wire 2, are connected to the terminal 1. Two aluminium paddles, 5, are free to rotate on knife edges, 6, within cages 3 and 4. The aluminium pointer attached to the spindle of the paddles, 5, has the lower end flattened out and dipping in a metal box, 7, containing oil, thus damping the occasional violent movements of the pointer.

Having already traced the high-pressure connections, I will now trace the connections to earth. The brass stud 10, shown in the other view of the meter, is connected to the back knife edge, and so to the paddles, and is also connected to strip of tinfoil pasted on to the glass front of the meter. The metal-box, 7, is connected to the front knife edge by a wire or piece of tinfoil, and the metal dial, 8, is also connected to the knife edge. So it will be seen that all metal work in the meter is connected to earth, except the metal cages 3 and 4. I found that after the meters had been in use two or three months there was a white deposit on case close to lower edges of cages 11, all brass or copper objects were corroded with a green substance, steelwork (knife edges, etc.) very rusty, and the face of the dial destroyed. The aluminium parts were unaffected. When it was dark I could see tiny sparks passing at points indicated 11, from box 7 to supporting piece 9, made of some compressed insulating material and all round knife edges. I therefore came to the conclusion that nitrous oxide was formed inside the meter case by the passage of these sparks, and this gas attacked the metal work. The nitrous oxide would attack the copper or brass, forming copper nitrate, and thus accounting for the blue colour.

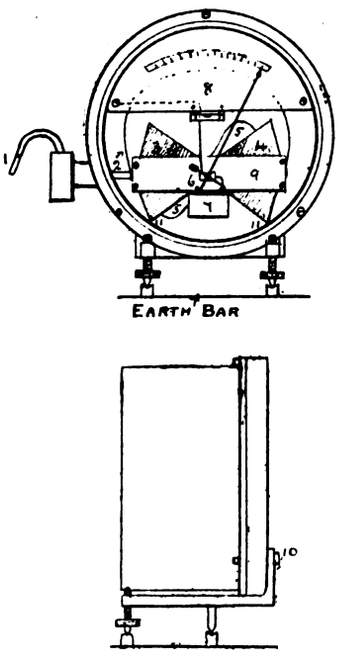

FIG. 1.

The whole bother lies with this sparking, which is apparently caused by different parts of the meter being charged at slightly different potentials, and the remedy is to keep all the earth connections spotlessly cleaned, and ensure that all parts are efficiently earthed. If this is not done, the meter will quickly want many parts renewed, and the needle will occasionally stick, and read inaccurately.—W. A. T.

Answer to No. 799 (*awarded* 7*s.* 6*d.*).—The chief cause of this trouble is moisture settling on the neighbourhood of the terminals and places which get corroded. This moisture holds particles of dust, some of which are partly composed of soluble mineral matter, and it also dissolves the gases such as carbonic and sulphurous acids, often present in the atmosphere of towns and factories. These make a conducting film for the electricity across the surface of the ebonite, etc., plates, and so electrolysis is set up, the result of which is the corrosion of any positively electrified metal, and, of course, if a thin wire is attacked it is soon eaten through, and the instrument fails to act. Any smoke from the furnaces or ashpits getting to the voltmeter would be particularly apt to cause the trouble. If a wire is not actually broken by the corrosion, probably a thin layer of non-conducting matter will be found between the terminal and the ebonite or other base to which it is fastened. If the terminal is brass this non-conducting layer will be green; if lead, then the layer will be white. It is caused by the action of the current, which dissolves a little of the metal of the terminal during the time the current passes, and then carbonic acid gas attacks the metal in solution and forms a salt such as carbonate of copper (green) or carbonate of lead (white). There are also other salts which might be formed, but their action would be to the same effect—*i.e.*, they would force the metallic face of one conductor from another and so insulate, when the instrument would refuse to act.

It is, moreover, just possible that circumstances might admit a more insidious and deceptive fault—viz.: the films

Digitized by Google

of moisture, etc., to act as a varying shunt across the terminals of the instrument, and so cause inaccurate readings. The best remedy would be to thoroughly clean and re-lacquer the instrument, and then to put it in a good dust-proof case, and place it in a warm, dry situation. If a dry situation cannot be found then put a saucer holding a few fragments of chloride of calcium in the bottom of the case. All the while these appear dry the air in the case will be dry, as they absorb moisture very rapidly. When they appear very wet or a solution accumulates in the saucer, take it out and put it in an oven to dry. It will then be fit for use again, and may be put in the case as before. The chloride of calcium should not be fused every time it is dried. If, however, it does get fused it should be broken up into rough pieces, so as to expose as much of its surface as possible. It is quite easily broken when cold, and the operation may be repeated many times. Chloride of calcium absorbs moisture when cold, and parts with it when heated.—F. G. A.

Answer to No. 799 (*awarded* 5*s.*).—Due to insufficient wording, it is very difficult to say what precisely is *the* requirement of the questioner. To the writer there appears to be two possible renderings of the questions: first, as regards the reason or cause of the corrosion; and, second, as regards the reason why there should be any trouble consequent upon the corrosion occurring. Also, the information in the question would have been greatly enhanced if the querist had been a little specific as to what he means by "the metal parts"—that is, as to whether this phrase refers to the internal fittings or to the external case. If the former is the case, then it is very difficult to see exactly why corrosion should take place, unless the meter is not hermetically sealed, and it has been placed in a humid atmosphere or an acid-laden atmosphere. Then, if moisture—either water or acid—found its way into the meter, corrosion would, as a consequence, occur. This applies also, of course, to the case of the corrosion of any metal parts that may be fixed on the case, and also of the corrosion of the case itself.

Concerning the question of the trouble which arises, very little can be said, because the question does not state what the trouble is. If it is due to leakage, then it is clear that it is due to the provision of a leakage path or paths by the acid or water settling on or in the instrument. If such is the case, then it is not correct to say that the trouble is due to the corrosion of the metal parts.—G. W. Burley.

Question No. 800.—Will a Kelvin multicellular voltmeter give the R.M.S. volts when connected across the secondary of a pressure transformer? The high-tension pressure is 2,000, and the transformer ratio 20 : 1.

Answer to No. 800 (*awarded* 7*s.* 6*d.*).—For the purposes of deciding this question I will first consider the law of a multicellular voltmeter which is, of course, that of a quadrant electrometer. Let V_1 and V_2 be the potentials of the two parts of quadrants, and V_3 the potential of the needle. Then the deflection of the needle, d, is given by the formula

$$d = k\,(V_1 - V_2)\left(V_3 - \frac{V_1 + V_2}{2}\right). \quad . \quad . \quad (1)$$

k being a constant depending upon the instrument. The above voltages are supposed to be steady. Now, if, as in the question, the current is alternating the voltage at any instant is given by V sin pt where V is the maximum voltage. We can now substitute this value for each of the voltages in equation (1)

$$d = k\,(V_1 \sin pt - V_2 \sin pt)\left(V_3 \sin pt - \frac{V_1 \sin pt + V_2 \sin pt}{2}\right)$$

$$= k \sin^2 pt\,(V_1 - V_2)\left(V_3 - \frac{V_1 + V_2}{2}\right) \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Now, it will be seen that we may replace, for the purposes of simplification, the last two terms of equation (2) by a term, E^2, since V_1, V_2, and V_3 are constants. This equation now becomes reduced to

$$d = k\,E^2 \sin^2 pt;$$
$$= k\,(E \sin pt)^2 \quad . \quad . \quad . \quad . \quad . \quad (3)$$

From the above it will be seen that the needle is being subjected to a succession of impulses, and, of course, it will not vibrate, but will take up a steady position. Now, the real point in this question is to find the voltage which, if produced continuously, would give the same deflection of the needle as the one above, which is alternating. This will be, perhaps, better explained by aid of Fig. 1. The

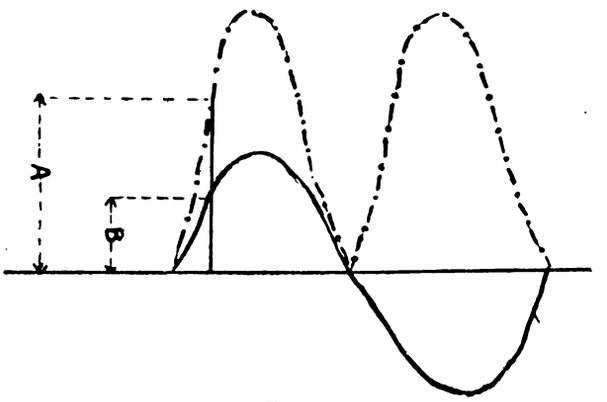

Fig. 1.

full line represents the pressure, and the broken line represents the impulse on the needle, which, as shown above, is proportional to the square of the pressure. Now, the needle will take such a position as if it were actuated by a continuous impulse represented by the mean ordinate of the impulse curve. The height of this ordinate is represented in the diagram by A. Now, this impulse is produced by the voltage represented by B, and it is the voltage that we have to find. To find this we must obtain the area of the impulse curve, and divide it by its length, which will give us the mean ordinate. The area of the curve is given by

$$\int_0^{\frac{\pi}{2}} k\,E^2 \sin^2 pt = k\,E^2\,\frac{\pi}{4}.$$

Its length is $\frac{\pi}{2}$.

Therefore its mean ordinate is $\dfrac{k\,E^2\frac{\pi}{4}}{\frac{\pi}{2}} = \dfrac{k\,E^2}{2}$.

This gives us the mean impulse. The voltage producing the impulse is given by

$$\sqrt{\frac{E^2}{2}} = \frac{E}{\sqrt{2}}.$$

Thus $\frac{E}{\sqrt{2}}$ will easily be recognised as the root mean square of the voltage. I think, therefore, that I have shown that a multicellular voltmeter will give the R.M.S. of the applied voltage.—Ernest P. Hollis.

Answer to No. 800 (*awarded* 7*s.* 6*d.*).—The Kelvin multicellular voltmeter is a perfectly suitable instrument for any alternate-current work, if it be remembered that this type of instrument possesses a very small but definite capacity, and hence forms a condenser. A minute charge and discharge current is set up when connected to an alternating circuit, and if the voltmeter be shunted across some part of a circuit carrying current, this current must be sensibly large compared with the voltmeter current, say ·25 to ·5 ampere, or an error is introduced by the lowering of the P.D. between the points on the circuit to which the voltmeter is connected. This drop in the voltmeter is clearly only worth considering when small readings are taken, but reference to it may be useful if small portions of the secondary winding be tested.

Even if calibrated with direct current, the voltmeter reads correctly the R.M.S. voltage, for since the couple tending to move the suspended vanes is proportional to the square of the P.D. applied the deflection produced by an alternating P.D., the R.M.S. value of which is E, will be the same as that produced by a continuous P.D. of value E, for the mean value of both couples is the same, or

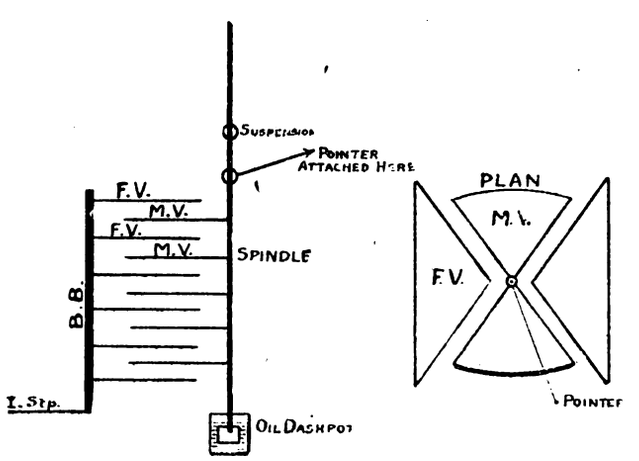
(continuous P.D.)^2 = mean square of alternating P.D.).

Digitized by Google

The instrument reads *absolutely correctly* R.M.S. volts, whereas an error of about one-fifth of a volt is introduced with direct current, owing to the fact that the movable part of the instrument is usually of aluminium, and the fixed part brass. As aluminium is electro-positive to brass, if the positive pole be connected to the needle the instrument will read ·2 volt below the correct value, and the same amount too high if the connections be reversed.—A. M. L.

Answer to No. 800 (*awarded* 7*s.* 6*d.*).—The Kelvin electrostatic voltmeters are based upon the well-known elementary fact that two adjacent bodies at different potentials mutually attract one another. The force of attraction is proportional to the square of the potential difference. A short description of the instrument and its working will make it evident that it will give the R.M.S. volts when connected as described, or between any two conductors carrying an alternating or direct current.

The multicellular instrument was designed in order to obtain a sufficiently great attractive force to give a distinct movement of the indicating pointer when measuring comparatively low differences of potential. A number of aluminium vanes are fixed on a vertical spindle horizontally, and are all equidistant from each other, and also metallically connected to one another. The spindle is supported by platinum iridium wire, the spindle also carrying the indicating pointer. There are also a number of fixed conductors, between which the aluminium conductors on the spindle are free to move, but owing to suitably



placed stops the fixed and the moving conductors can never come into actual metallic contact. These fixed conductors consist of triangular brass plates fixed into vertical brass back plates, and these plates, like the moving plates, are fixed equidistant from one another, and are all in metallic contact, but insulated from the outer brass case of the instrument, and are connected to an insulated terminal on the side of the case, the spindle carrying the movable aluminium vanes being connected to the case through the platinum iridium suspending wire. When a difference of potential is set up between the fixed and moving vanes, the attractive force urges the moving vanes to come inside the fixed vanes. A special vane, carried on an extension of the spindle, and immersed in an oil bath, acts as a dashpot, and steadies the movements of the moving vanes. The force of attraction between the fixed and moving vanes varies as the square of the potential difference between them, and thus directly indicates the value of the square root of the mean squares of the potential difference between the plates, or the R.M.S. as generally written; the instrument is also, through being electrostatic, quite free from any self-induction effects, and is thus correct for any periodicity. The accompanying sketch shows diagrammatically the working of the instrument. B B. represents the brass backs, F.V. the fixed and M.V. the moving vanes, whilst I.stp. represents the insulated brass strip connecting B.B and the fixed vanes to the insulated terminal on the outside of the case. The view-marked plan will also give a good idea of the working and construction of the instrument.

There are, it will be noted, two sets of moving and two of fixed vanes, the object being to obtain a fair deflection with ordinary pressures, the original instrument with only one pair of fixed and one pair of moving vanes being unable to give suitable deflections under about 1,500 volts. With the multicellular instrument, by using a small transformer whose primary is connected across the high-tension bars and the secondary to the instrument, as in this case, the voltmeter can be calibrated to give accurate readings of the difference of potential between the high-tension bars, and thus obviate the necessity for carrying high pressures on the instrument itself.—W. T. W.

Answer to No. 800 (*awarded* 5*s.*).—The Kelvin multicellular voltmeter reads R.M.S. volts when connected to an alternating-current circuit. In the case mentioned by "H. C. H." the voltmeter would read 100 volts when connected to the secondary circuit of the potential transformer having a 20 : 1 ratio, the primary volts being 2,000. With an electrostatic voltmeter (such as the one mentioned above) there is, of course, no voltage drop on the secondary of the transformer due to its resistance, since there is no current flowing in the voltmeter. With a well-designed potential transformer there is no appreciable drop on the secondary when a current-consuming voltmeter is connected to it. There is a point to be noted in connection with the Kelvin multicellular voltmeter, and that is the contact potential difference due to the use of different metals in it. The makers state in their pamphlet what this contact P.D. amounts to. In the old type vertical multicellular voltmeter, when one terminal, say A, was connected to the positive main, and the other terminal, B, to the negative main, the voltmeter would read 0·2 volt low. With the connections reversed—*i.e.*, A negative and B positive—the instrument would read 0·2 volt high. On an alternating-current circuit the instrument read correctly. If "H. C. H." is using his instrument with a reflecting mirror these small P.D.'s will be easily readable. If he is making a new scale, a direct-current potentiometer will be necessary, and he will find it convenient to make, say, A positive in the test and mark off his scale. Then the instrument connected with A positive has no error, but with alternating current it will read 0·2 volt high. With A negative the voltmeter would read 0·4 volt high, so that care must be taken to see that the polarity of the instrument is correct, as when first tested with potentiometer.—L. S.

Answer to No. 800 (*awarded* 5*s.*).—The electrostatic voltmeter will give the root mean square value of the volts whether the voltage be represented by a peaky, a flat-topped, or by a sine curve. It is only in the case of the rising and falling E.M.F. taking the form of a sine curve that the apparent volts multiplied by $\sqrt{2}$ gives the maximum voltage. If the potential be taken on the primary side and also on the secondary side of the transformer, the readings, allowing, of course, for ratio of transformation, will give the root mean square of the voltages. Should the voltage curve of the energy supplied to the transformer be peaky, that on the secondary side will be peaky also, if flat-topped the secondary will be flat-topped, or if the primary voltage may be represented by a sine curve the secondary voltage will also take the form of a sine curve. Generally the curve of potential on the secondary side is but a reproduction of that on the primary.

The question as to whether a peaked or a flat-topped curve is the better is, of course, another matter. For arc lighting a flat-topped curve is considered to give the best results, while a sine curve is generally preferred for motors. For a given amount of energy a peaked curve will give a minimum loss in the iron of a transformer. With a peaky curve the insulation must be of a higher order than when the E.M.F. is represented by a curve of the flat-topped variety. "H. C. H." will get the R.M.S. voltage by means of his multicellular voltmeter, but only in the case of a sine curve will this multiplied by $\sqrt{2}$ give the maximum potential. Even supposing the generator supplying the transformer to give a sine curve under normal conditions, the load may be such as to alter its potential very considerably from a simple sine curve. Thus a generator supplying a bank of unloaded transformers will give a different curve to that which it will give when the trans-

Digitized by Google

formers are all fully loaded. The form taken by the voltage curve is of considerable importance when machines or transformers are to be coupled up in parallel.—M. M.

Question No. 801.—Show how to calculate the ampere-turns needed to balance the armature reaction of a polyphase alternator working at power factor cos ϕ.

Answer to No. 801 (*awarded 7s. 6d.*).—Before we can make this calculation it is necessary that we should obtain certain data from the polyphase alternator under consideration. To do this two distinct tests have to be made on the machine. The first of these is a no-lead excitation test, which enables us to plot a curve connecting the exciting current with the open-circuit voltage per phase. In making this test, the alternator is belted to a motor of sufficient capacity to run the alternator light, and then run at its normal speed. The open-circuit voltage corresponding to various values of the exciting current is measured, the exciting current being varied between such limits as to give a range of voltage from 0 to 20 per cent. over the full-load voltage of the alternator. From these readings a curve can be plotted similar to that shown in Fig. 1.

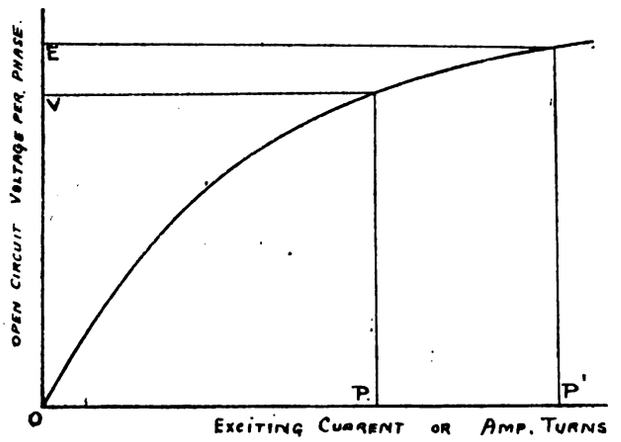


FIG. 1.

The second test is an impedance test, from which we can calculate the armature reactance per phase. As before, the machine is run at its normal speed, but with the phases short-circuited through three ammeters sufficiently large to carry the full-load current. These ammeters are connected either in star or mesh, to correspond with the winding of the alternator. A small exciting current is then put on, and adjusted so as to give the full-load current as indicated by the ammeters. Two or three check readings should be taken with smaller exciting currents, the ammeter readings (which should be equal) corresponding to the different exciting currents being in each case noted. Now, suppose that with an exciting current of *a . amps.* the reading on each of the ammeters was *C*. By a reference to the curve plotted from the no-load excitation test, we find that corresponding to an exciting current of *a . amps.* the open-circuit voltage per phase is *E*.

We can then put

$$C = \frac{E}{\sqrt{R^2 + L^2 p^2}}$$

or

$$L p = \frac{\sqrt{E^2 - R^2 C^2}}{C},$$

where $L p$ = armature reactance per phase,

R = resistance per phase (which can readily be determined).

We are now in a position to make the calculation required. In Fig. 2 a vector diagram is drawn, which shows the state of affairs when the alternator is loaded with a current of *I . amps.* lagging by an angle, ϕ. Here we have

O I = current per phase.

ϕ = angle of lag.

O V = line voltage per phase.

The reactance voltage per phase is found by vectorially compounding O C and O A, where

O C = ohmic drop per phase = I R.

O A = reactance drop per phase = $L p I$ (at 90deg. to O C).

Then O B = reactance voltage per phase.

The resultant of O V and O B gives us O E, which represents the actual voltage which has to be induced in each phase to give us a line voltage of O V, when the alternator is loaded with a lagging current of O I working at a power factor cos ϕ.

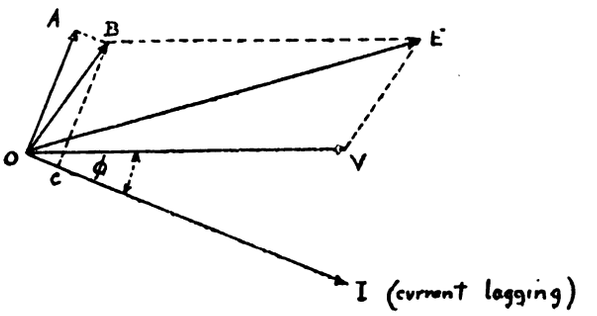

FIG. 2.

From Fig. 1 we find that the ampere-turns (which are equal to the exciting current × total turns on field-magnet system) corresponding to a line voltage O V, are O P, and the number required to give an induced voltage per phase of O E is O P'. The difference O P' − O P = P P' gives the ampere-turns required to balance the armature reaction corresponding to a line current, O I. In the case where the current leads by an angle, ϕ, exactly the same procedure is followed as previous. Fig. 3 represents this case,

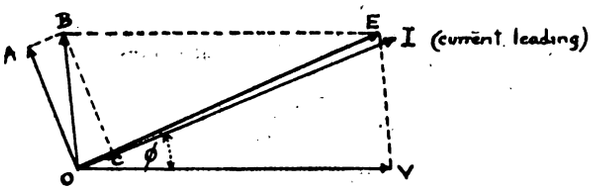

FIG. 3.

exactly the same lettering being used as in Fig. 2, O V representing the line voltage, and O E being the actual induced voltage per phase. By comparing with Fig. 2, it is readily seen that for the same current, O I, O E in Fig. 3 is much less than O E in Fig. 2. This means that the ampere-turns, for this particular power factor, required to balance the armature reaction is less for a leading current than what it is for a lagging current. In fact, with a leading current it is seen that there is a certain value of ϕ which gives O E = O V—*i.e*, for this particular lead the armature reactance has been exactly neutralised.—A. P. YOUNG.

Testing of Rubber-Insulated Wire.—The Wire Inspection Bureau affiliated to the Underwriters' Laboratories of Chicago and New York, recently held a conference for the purpose of devising ways and means of testing all rubber-insulated wire manufactured under the rules of the National Board of Fire Underwriters, and to prevent the introduction into commercial use of any such wire which would prove inferior to the standard demanded by the National Board of Fire Underwriters. It was decided to appoint electrical inspectors, three being considered sufficient at present, who shall from time to time visit the testing laboratories of any factories making rubber-insulated wire, and make, supervise, and verify tests specified by the bureau. The expenses of these inspectors is to be paid by fees collected from the manufacturing companies whose product is tested, each company paying its share in proportion to the amount of wire manufactured. This will be collected as payment for labels for each coil of wire, specifying that the standard tests have been applied.

AUGUST 25, 1905.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

808. Can any of your readers give any information as to the costs of working of petrol or petrol-electric motorcars on rails, either in this country or abroad?—R. G.

809. In a station having water-tube boilers working at 200lb. per square inch, and using salt water for condensing, what is the best and quickest method of detecting small quantities of salt in the feed water? The presence of the salt being due to a leaky condenser. As it is desired to avoid "blowing down" as much as possible, to what density may the water in boilers be allowed to rise to before forming a dangerous scale? What percentage of the feed water should be "blown down" daily to maintain the density at a safe value?—PRACTICAL.

ANSWERS.

Question No. 801.—Show how to calculate the ampere-turns needed to balance the armature reaction of a polyphase alternator working at power factor cos ϕ.

Answer to No. 801 (*awarded* 10*s.*).—The armature reaction in an alternator for a given load is dependent on the power factor of that load. Consider the hypothetical case of an alternator, the armature of which is non-inductive, working on a non-inductive external load. The current in the armature conductors will reach its maximum value at the same instant as the maximum value of the E.M.F. occurs, and the position of the armature coil for this condition is shown in Fig. 1A, where the coil is shown in "mid-pole-face" position. The demagnetising effect of the armature current, when the maximum value of the current corresponds to this position, is evidently a minimum. In modern alternators the maximum value of the armature current, when working on a non-inductive load, occurs somewhat later than the mid-pole-face position, due to the reactance of armature coils.

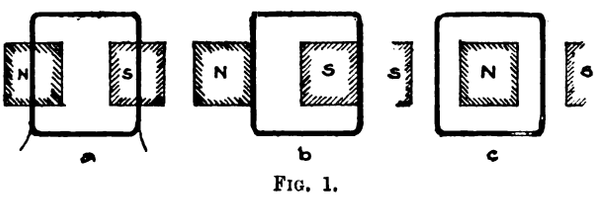

FIG. 1.

If, however, the external load possesses considerable inductance, the maximum value of armature current may occur when the coil is opposite the pole corners, as in Fig. 1B. When the maximum value of the current occurs with the coil in the position shown in Fig. 1C (corresponding to a power factor of 0), the demagnetising effect of the armature is a maximum. From the position shown in Fig. 1A to that in Fig. 1B the demagnetising effect increases very rapidly, and after this position it increases much more slowly, the maximum value occurring for the position shown in Fig. 1C. It is sufficiently accurate for calculations of armature reaction to consider that the demagnetising effect of the armature increases in proportion to the sine of the angle of lag between mid-pole-face position and positon of armature coils when carrying maximum current.

It is customary in designing three-phase alternators to consider the resultant magnetomotive force of the armature winding to be equal to twice the magnetomotive force of one phase. This convenient rule calls for the armature winding to be so arranged that the phase difference of the E.M.F.'s generated in each of the three windings is 60deg. (see Fig. 2A). By reversing the connections of the intermediate phase, the voltages between the terminals become 120deg. apart in phase, as shown in Fig. 2B. From Fig. 2A it will be observed that the resultant of the three vectors shown has a value of 2, each vector being assumed to have a value of unity. It should be noted that the calculations on alternators are generally made on the assumption of the machine giving a sine wave.

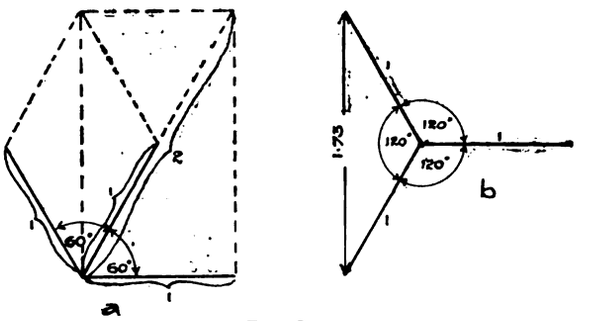

FIG. 2.

A three-phase machine will now be examined, and the armature reaction calculated for various power factors. The example below is taken from a three-phase machine of the revolving-field type, the leading particulars of which are given in the following specification*: rated output, 850 kw.; speed, 94 r.p.m.; periodicity, 25 ~; number of poles, 32; terminal voltage, 5,000 volts; voltage per phase, 2,880 volts; full-load current per phase, 98·5 amperes. The stator has 192 slots of the "open" type, and each slot contains 14 conductors, hence there are 14 turns per pole per phase.

The average value of the reactance for all positions is 9·6 ohms at 25 ~. We will now calculate the ampere-turns necessary to maintain a constant terminal voltage of 5,000 volts with full-load current at various power factors.

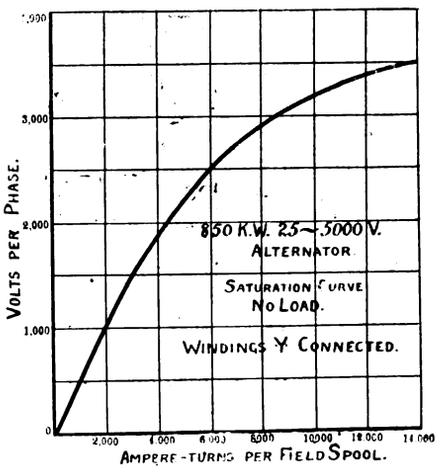

FIG. 3.

1. *Unity Power Factor.*—The reactance voltage at a load of 98·5 amperes = 9·6 × 98·5 = 945 volts per phase. Now, when the external load is non-inductive, the angle of lag of

*A description of this machine is given in "Traction and Transmission," vol. x., p. 28, by Messrs. Parshall and Hobart.

Digitized by Google

the maximum value of the armature current behind the mid-pole-face position is given by :

$$\tan^{-1}\frac{\text{reactance voltage per phase}}{\text{terminal voltage per phase}}=\frac{945}{2,880}=\cdot328.$$

$\tan^{-1}\cdot328=18^\circ\ 10'$. $\sin 10^\circ\ 18'=\cdot312$.

Assuming a sine wave current curve, the maximum resultant armature turns per pole at full load are :

$$14\times98\cdot5\times\sqrt{2}\times2=3,900 \text{ ampere-turns.}$$

Hence the demagnetising effect of the armature when working on an external non-inductive load of 98·5 amperes is

$$3,900\times\cdot312=1,215 \text{ ampere-turns.}$$

Therefore, when this machine is working at full load, with a power factor of unity, there is required 1,215 additional ampere-turns above that required at no load, in order to maintain a constant voltage of 5,000 volts between terminals at a constant speed of 94 r.p.m. The no-load saturation curve for this machine is given in Fig. 3, from which the no-load excitation for 2,880 volts per phase (corresponding to 5,000 volts between terminals) is found to be 7,650 ampere-turns per field spool. As the resistance per phase is ·405 ohm, the volts drop at full load = 30 volts per phase, and internal E.M.F. to be generated at full load in order to give 2,880 terminal volts per phase = 2,910 volts. The field excitation to give this voltage at no load is found to be 7,670 ampere-turns. Hence the field excitation when the machine is working at full load and unity power factor is 7,670 + 1,215 = 8,885 ampere-turns per field spool.

2. *Eighty per Cent. Power Factor.*—For a power factor of ·8 in the external circuit, the construction shown in Fig. 4 may be adopted. Lay off the angle $a\ c\ b\ (\theta)=18^\circ\ 10'$, the tangent of which is $\frac{\text{reactance voltage}}{\text{terminal voltage}}$. From a lay off the angle $c\ a\ d\ (\phi)$ to equal $\cos^{-1}\cdot8=37$deg., making $a\ d$ equal to $a\ c$. Join $b\ d$ and draw $d\ e$ at right angles to $a\ c$.

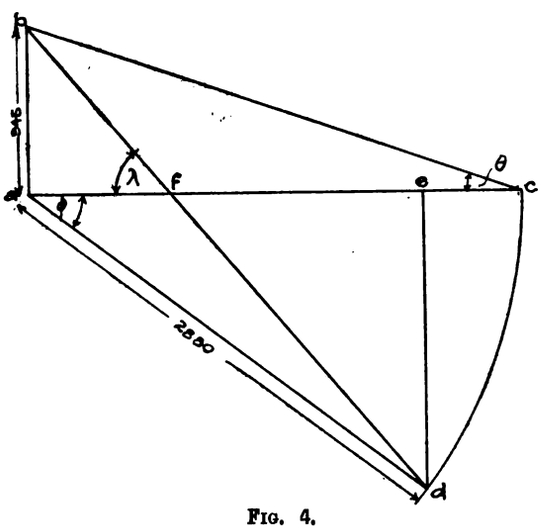

FIG. 4.

The angle of lag between mid-pole-face position and position of maximum current is now given by angle $a\ f\ b\ (\lambda)$.

$$\text{Now, } \tan\lambda=\frac{a\,b}{a\,f}=\frac{a\,b+c\,d}{a\,c}$$

$$=\frac{945+a\,d\sin 37\text{deg.}}{a\,d\cos.\ 37\text{deg.}}$$

$$=\frac{945+(2,880\times\cdot6)}{(2,880\times\cdot8}=1\cdot16.$$

Hence $\lambda=49\cdot2$deg.

and $\sin\lambda=\cdot735$.

Therefore, demagnetising component of total armature strength = 3,900 × ·755 = 2,950 ampere-turns.

Therefore, to maintain 5,000 volts between terminals with a load of 98·5 amperes at a power factor of 80 per cent., an excitation of 7,670 + 2,950 = 10,620 ampere-turns per field spool will be required. A similar construction will give the excitation required for other power factors.

3. *Zero Power Factor.* — In this case the armature demagnetisation will approach it maximum value as the maximum value of the current occurs when the armature coil is in the position shown in Fig. 1C. Hence the armature demagnetising effect is, in this case, equal to 3,900 ampere-turns, and the excitation required to maintain 5,000 terminal volts with a load of 98·5 amperes at a power factor of 0 will be 7,670 + 3,900 = 11,570 ampere-turns per field spool.

TABLE I.

Power factor of external load.	Ampere-turns per field spool required to maintain a constant potential of 5,000 volts between terminals at 94 r.p.m. for various power factors.		
	Full load.	Half load.	Quarter load.
Unity	8,885	7,940	7,735
95%	9,850	8,535	8,030
90%	10,200	8,740	8,145
80%	10,620	9,000	8,285
60%	11,110	9,310	8,460
20%	11,520	9,580	8,615
0	11,570	9,610	8,630

Table I. has been calculated out for three different loads

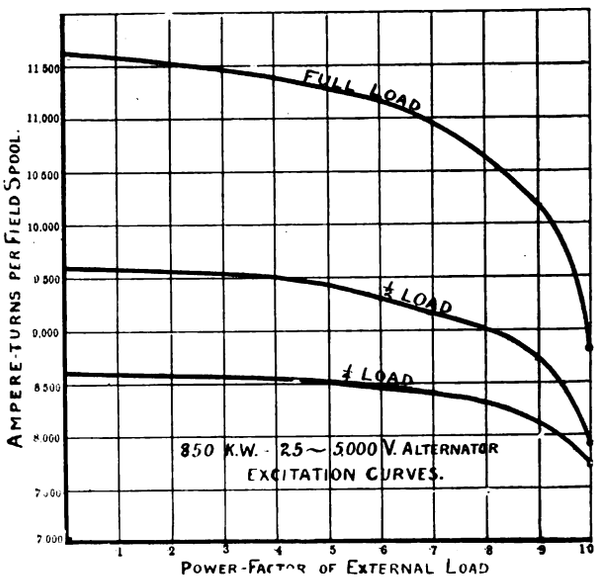

FIG. 5.

and various power factors, the results being plotted in Fig. 5.—MONOPHASE.

Answer to No. 801 (*awarded 7s. 6d.*).—There are four main considerations governing the pressure drop in any alternating-current generator. By pressure drop is meant the rise in voltage that will occur when full load is thrown off the machine and speed and excitation are kept normal. These factors are (1) armature reaction; (2) armature leakage; (3) increasing field leakage with load; (4) ohmic losses in armature and eddy currents in pole-pieces. We are considering the first of these, and, since corrections may afterwards be applied for the rest, we may leave them out of count for the present. In order that we may be in a position to calculate the effect of reactions under all conditions of load and power factor, we need to know both the no-load characteristic and the short-circuit current curves for the machine in question, which we will assume is built. To obtain the first, run the machine at its rated speed and plot the relation between terminal potential difference and field ampere-turns. The second curve is obtained by short-circuiting the terminals of the machine—inserting an ammeter in one phase—and while running it at a convenient speed plotting the relation between field ampere-turns and short-circuit current as given by the ammeter. In cases of original design the designer must rely on his own experience to guide him in constructing hypothetical curves.

Now the resultant reactive ampere-turns of a three-phase armature can be shown to be one and a-half times the maximum value of the current wave (in the case of a three-phase machine) multiplied by the number of turns per phase in the armature winding—k_1, C_a, S_a, where C_a and S_a are armature current and turns per phase respectively, and k_1 is a constant depending on the shape of the E.M.F. wave and the number of phases in the machine—being

Digitized by Google

equal to about 2·25 with average three-phase machines, and 1·5 to 1·6 for two-phase machines (see A. C. Eborall's "Polyphase Electric Working"). Let O P (Fig. 1) represent the phase of the current in a short-circuited armature. Now the armature leakage flux being in phase with this,

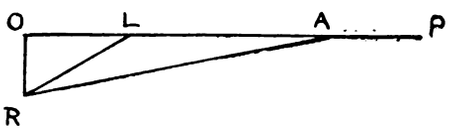

FIG. 1.

may be represented by O L in magnitude. But the E.M.F. generated in the armature by the main flux is in phase with this current, also, since the circuit is made up of the ohmic resistance of the armature. Hence O R will give the magnitude and phase of the armature flux (in quadrature with E.M.F.), R L, the resultant is the field excitation necessary to generate the E M F. The resultant reactive armature ampere-turns being in phase with the current, may be represented by L A, whence the total field ampere-turns are R A. Note that the angle O A R will be small in well-designed machines, so the R A approximately equals A L+O L.

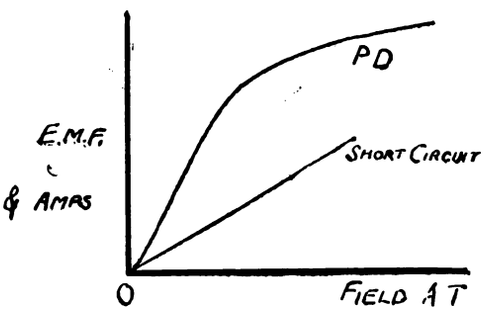

FIG. 2.

Fig. 2 gives the no-load characteristic and short-circuit curves of an alternator. Let E represent the terminal E M F. per phase in a load of C amperes where cos $\phi = 1$. Let O E in Fig. 3 represent the E.M.F. in magnitude and phase. Then O N gives the phase of the main flux produced by the ampere-turns, T_1 (see Fig. 2). Let O T_1 represent these. The reactive ampere-turns of the armature, or rather the field, A T, needed to counteract them, is given from the short-circuit curve as T_s (Fig. 2). These are practically in phase with the load current, O C, as shown above, so that we may represent them by O T_s. Then, T_1 T_s gives the ampere-turns needed on the field to give a load current of C amperes at a terminal pressure of E volts per phase. In cases where cos ϕ is not equal to unity it is merely necessary to plot O T_s, the armature reaction vector making

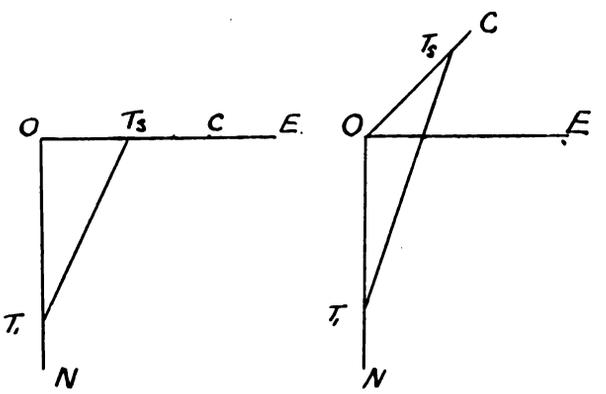

FIG. 3.

an angle ϕ (lag or lead) with O E (as shown in Fig. 3A) where cos $\phi = \cdot 7$, current lagging. A study of the figures will show that a leading current will reduce the pressure drop, while a lagging current has the opposite effect. The explanation of this is as follows: When the power factor is unity, the position of those coils carrying maximum current is such that their axes in each case lie midway between the field poles (the most active conductors lying in the densest field). This results in a *distortion* of the flux, but seeing that the reaction in both north and south poles is equal owing to position, the net *reaction* is nil. Now, a lagging current causes these same active conductors to take a position, relative to the maximum flux, in the rear of the previous one, with the result of a reduced flux in the armature (see

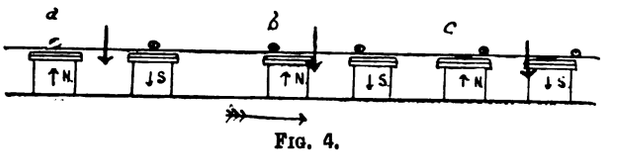

FIG. 4.

Fig. 4). A leading current has, of course, a similar but opposite action.—PERPLEX.

Answer to No. 801 (*awarded 7s. 6d.*).—One of the simplest methods of calculating the armature reaction effect in alternators, and one which at the same time is probably quite as reliable as any of the more elaborate rules, is that based on a consideration of the short-circuit current. When an alternator armature is short-circuited and run at approximately normal speed, there is a certain definite small number of exciting ampere-turns which will cause the normal full-load current to flow in the armature. This number of ampere-turns corresponds to a certain open-circuit terminal voltage, v, and this voltage may, without appreciable error, be taken as equal to the inductive, or armature reaction, drop due to the normal full-load current. When v is known it is easy to arrive at the volts which must be produced at the terminals on open circuit in order to obtain without change of excitation any required voltage at full load with any given power factor. Now v can be predetermined from the fact that, for modern alternators of a given type and number of phases, a fairly fixed relationship exists between the field excitation ampere-turns and the ampere-turns produced in the armature on short-circuit. This relationship can be stated as—

$$\text{Field exciting ampere-turns per pair of poles} = \text{Armature turns per phase per pair of poles} \times \text{Armature current per phase on short-circuit with the given field ampere-turns} \times C \qquad (1)$$

where C has the following approximate values for ordinary slotted alternators with rotating radial pole magnets, alternately north and south:

C = 1·5 for single or two phase alternators;

C = 2·7 for three-phase alternators.

A more exact value for C can always be obtained by making a short-circuit test on an alternator of the same, or nearly the same, type and proportions as the one under consideration. Inserting the correct values in equation (1), the number of field ampere-turns per pair of poles required to produce normal full-load current on short-circuit is obtained. By calculation with the air-gap and iron dimensions of the alternator in the ordinary way, the value of the flux, and, therefore, of the voltage per phase produced by this excitation at normal speed and with no current in the armature, is arrived at = v.

The resultant of this inductive or armature reaction drop, v (which is in quadrature with the armature current), and the required terminal voltage, V (which is at a phase angle ϕ to the armature current), gives the voltage, E, which must be induced in the armature on open circuit if the terminal voltage at full load and with power factor = cos ϕ is to attain the required value, V, assuming armature reaction alone and no resistance drop to be present. It is then only necessary to carry out the ampere-turn calculation (by means of the air-gap and iron dimensions) for the fluxes corresponding to the no-load voltages of V and E respectively, and the difference between these two numbers of ampere-turns is the number of ampere-turns required to compensate for armature reaction. The value of E for a given value of V, and of v on a load of any given cos ϕ, is obtainable by means of the simple vector diagram shown in Fig. 1. Let A C represent the phase of the armature current. Draw A B at an angle ϕ to A C, and of such a

Digitized by Google

length as to represent the required full-load voltage, V, to any scale. From B draw B D at right angles to A C and equal to the armature reaction drop, v, to the same scale. Then A D is the resultant of V and v, and is, therefore, equal to E. It will be seen that this method of obtaining the armature reaction ampere-turns simply consists in

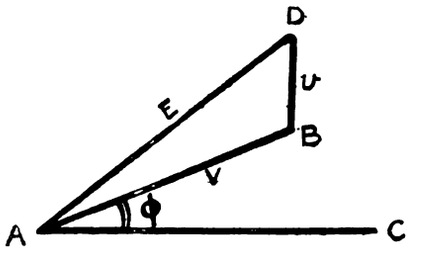

Fig. 1.

finding two points on the no-load characteristic (Curve I., Fig. 2) of the alternator. The first point, V, is the voltage required at full load, and the second point, E, is the no-load voltage produced by the ampere-turns which give the required voltage, V, at full load, and with the given power factor cos ϕ, the effect of resistance drop being omitted. Curve II. (Fig. 2) represents the full-load characteristic (omitting resistance drop) at the given power factor of cos ϕ. The horizontal distance, a, between the two points V and E gives the number of ampere-turns required to compensate for armature reaction.

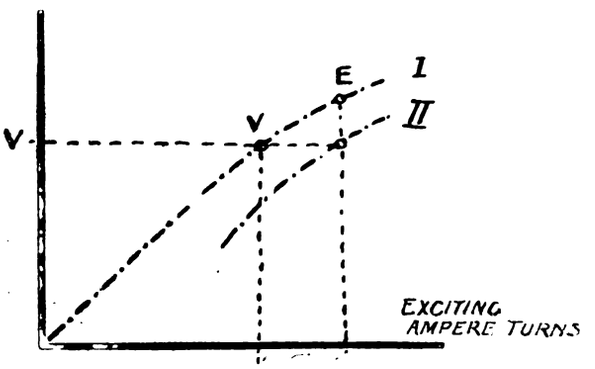

Fig. 2.

It may be mentioned that, owing to some of the assumptions involved, this method is found to give rather more importance to the armature reaction than is usually justified by the test results.—Q.

Answer to No. 801 (*awarded* 5*s.*).—The ampere-turns with which the stator acts on the field of the alternator are given by the expression

$$\text{ampere-turns} = -S \sin \phi,$$

where S = the back ampere-turns of the stator per pair of poles. The angle ϕ is considered positive when the current lags behind the voltage. When ϕ is positive the back ampere-turns have demagnetising effect on the field, and when ϕ is negative they have a magnetising effect on the field. The value of S can be found from the following expression:

$$S = Z\, i\, \frac{k}{m} \sin m \frac{\pi}{2},$$

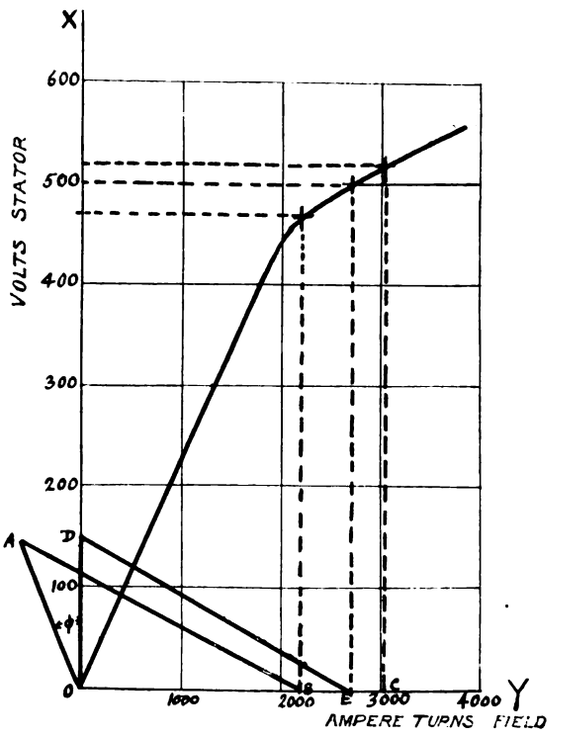
where Z = number of effective conductors per slot × number of slots per pole and phase;

i = current per phase stator;

m = the ratio of pole arc to pole pitch—this should not exceed two-thirds, or 66 per cent.;

k is a constant having the following values: for single-phase, $k = 0.57$; for two-phase, $k = 1.13$; for three-phase, $k = 1.68$.

The ampere-turns required by the other parts of the machine are found in the usual way by getting the densities, length of path, and ampere-turns required at that density per unit of length. Adding the back ampere-turns on to these, we get the total ampere-turns required for any particular load at any particular power factor and voltage. If we have obtained a "saturation curve" of the machine, either by test or calculation, it can be seen graphically what takes place in the machine. The saturation curve is a curve plotted between the volts (line) stator and the ampere-turns field. Referring to the accompanying sketch, it will be seen that at no load and 3,050 effective ampere-turns on the field we get 517 volts on the stator. Now, if $\phi = 0$, then the back ampere-turns of the stator would act along O X. Now, at a certain load let the back ampere-turns be O D, ϕ being O. Supposing that the field ampere-turns have remained the same, then, since the back ampere-turns act at right angles to the field ampere-turns, the resultant ampere-turns must, therefore, be less than O C. We really get a right-angled triangle, of which the hypothenuse is equal to O C. So the effective ampere-turns of the field are now only = $\sqrt{O\,C^2 - O\,D^2}$, or, graphically, from centre, D, and radius, O C, strike an arc, cutting the line O Y at E, then O E equal the effective ampere-turns field, which in this case correspond to 500-volt stator. If ϕ has some value, then the back ampere-turn stator must be drawn at an angle ϕ from O X, like A O, ϕ being taken as positive. Again, assuming that the field excitation



still remains the same, and striking an arc of radius equal to O C from centre A, we get the point B, so that our effective ampere-turns of the field are now only O B, which correspond to a voltage of 470 volts. Here the voltage drop due to the resistance and self-induction of the stator winding has been neglected.—F. L.

Large Turbines.—In our issue of the 11th inst. we referred to the order which the New York Edison Company had placed with the American Westinghouse Company for two 7,500-kw. turbo-generator units. It appears that simultaneously with this the New York Edison Company placed an order with the General Electric Company of Schenectady for two Curtis vertical turbines of the like capacity, from which it is evident that they intend making an all-round trial with this form of large prime mover. It may be mentioned that an aggregate of 500,000 kw. in Curtis turbines has been supplied or is on order in America and Europe, which, considering the comparatively short period they have been in the market, is a notable record.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

QUESTIONS.

810. Discuss means of speed regulation of alternating-current low-voltage motors, and state why the cost of variable-speed alternating-current motors exceeds that of constant-speed motors by a relatively high amount. What would be the best method for obtaining electrically a speed variation of 25 per cent. with a 1-h.p. alternating-current motor?—H. A. N.

811. It is desired to instal a motor-generator of 50 kw. capacity for interconnecting an alternating-current 2,000-volt 75 ~ system with a direct-current 460-volt system. The alternators are of the ironless core type, and the dynamos are compound wound. Describe the controlling arrangements for the set to be started up as a motor from the direct-current side, but to run either as an alternating-current or direct-current generator in parallel with the existing plant. Give a diagram of the necessary connections.—H. A. N.

ANSWERS.

Question No. 802.—Two rotary converters (three phase) are running in parallel on alternate-current side. They are connected on direct-current side with only positive of one and negative of the other closed. Explain how it is possible for a load to be taken off direct-current 'bus bars.

Answer to No. 802 (*awarded 7s. 6d.*).—The best way to deal with this question is to trace out the windings on a diagrammatic sketch of two two-pole rotaries with ring windings, and treat the rotaries as being generators. As the two machines must always run in synchronism, their armature angular positions will remain the same (under equal conditions). Following the paths through the armatures from positive to negative 'bus bars (Fig. 1): (1) part

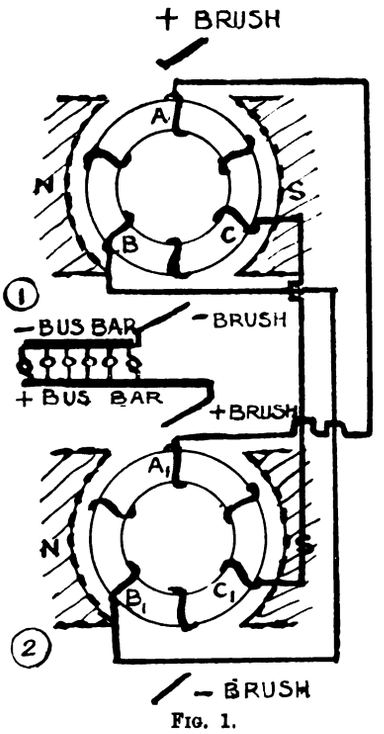

Fig. 1.

of current would flow from + brush (2) to A_1, by paralleling connection to A, thence through armature to – brush (1); (2) another part would flow from + brush (2), through armature (2) to C_1, by paralleling connection to C, through armature (1) to – brush (1); (3) the third part would flow from + brush (2) to B_1, thence to B and through armature (1) to – brush (1).

Summing up the E.M.F.'s in these paths it is readily seen that—

(1) E.M.F. (+ brush (2) to – brush (1)) = E;
(2) E.M.F. (+ brush (2) to C_1) + E.M.F. (C to – brush (1)) = E;
(3) E.M.F. (+ brush (2) to B_1) + E.M.F. (B to – brush (1)) = E;

where E = E.M.F. across rotary brushes.

It will be seen that for all armature angular positions these E.M.F.'s will always sum up equal to E. Hence, from + brush of one machine to – brush of the other there will be a continuous E.M.F. equal to that across brushes of one machine. It will be found that the E.M.F. between + brush (2) and A_1 will vary as Curve 1 in Fig. 2. Curve 2, half a period later in phase relation,

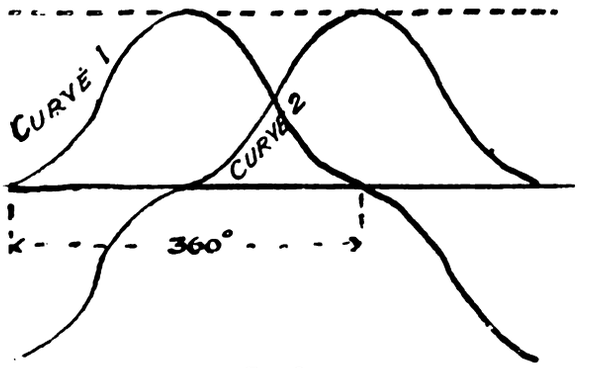

Fig. 2.

shows E.M.F. between A and – brush (1). Adding these two, we get a straight line + E.M.F. whose value is equal to that of the peak ordinate. Referring to Fig. 1, we find that when this peak E.M.F. is being generated, A_1 is in contact with – brush (2). Therefore, this continuous E.M.F. we get is equal to that across brushes of one rotary. In this method of connection nearly the same load could be taken from rotaries with same heating as when they are running in parallel on direct-current side, both on full load. This load would be about 75 per cent. of output of both rotaries.—J. R. S.

Answer to No. 802 (*awarded 7s. 6d.*).—By connecting the rotary converters on the direct-current side in the manner indicated the working of the machines has been very little altered, in so far that the load can be taken from the direct-current brushes, and, in general, the machines may be made to give an output equivalent to that of the two machines, although this would be undesirable owing to the undue heating of the armature which would result.

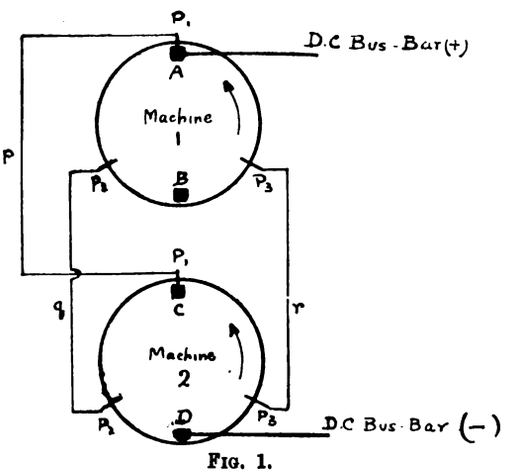

Fig. 1.

Fig 1 shows a diagrammatic view of the arrangement, the two machines being joined in parallel on the alternate-current side. The supply leads are taken off from P_1, P_2, and P_3, and as they do not concern us, for simplicity they are not shown. It is assumed that the machines are bipolar, as this supplies the simplest case. A and C are the positive and B and D the negative brushes of each machine, the

Digitized by Google

load 'bus bars being connected to A and D. P_1, P_2, and P_3 are the three points on the winding of each machine, each 120deg. apart, which are connected to the three slip rings. The winding, together with these three points, is supposed to rotate in the direction indicated by the arrow. For the position of the armatures here represented, the positive brush of each machine coincides with the point P_1. This means that for this particular moment the direct-current 'bus bars are connected directly across C and D—*i.e.*, the brushes of the second machine—and the 'bus-bar voltage will be equal to that across the brushes of either machine. Now, when the machines have advanced by one-sixth of a revolution from this point, it can readily be seen that each of the negative brushes will coincide with point P_2. That is, for this particular moment the direct-current 'bus bars will be connected across machine 1, and the 'bus-bar voltage will equal the voltage across the brushes of either machine. This will occur six times for each revolution, each machine being alternately connected for an instant directly across the 'bus bars. Not only will the 'bus-bar voltage equal the direct-current voltage of either machine at these six particular instants, but for any position of the armatures. Fig. 2 represents an intermediate position, and denoting for any instant the voltages between the positive brushes of either machine and the points P_1, P_2, and P_3 by V_1, V_2, and V_3 respectively, and the voltages between the

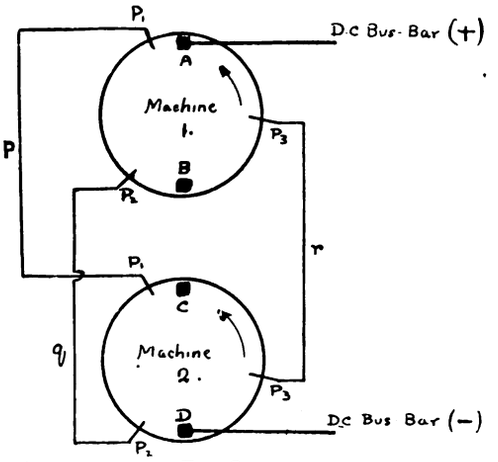

FIG. 2.

negative brushes and points P_1, P_2, and P_3 by V_4, V_5, and V_6, respectively, then we have

$$\left.\begin{aligned} V_1 + V_4 &= V \\ V_2 + V_5 &= V \\ V_3 + V_6 &= V \end{aligned}\right\} \text{'bus-bar volts.}$$

where V = direct-current voltage of either machine. That is, the voltage across the 'bus bars will be a direct-current voltage equal to that obtained across the brushes of either machine. The current taken from the direct-current 'bus bars will distribute itself unequally between the lines *p*, *q*, and *r*, and the load taken from the direct-current 'bus bars will share itself between the two machines, there being an alternate interchange of load between the machines, first one and then the other doing the bigger share. This interchange will occur six times for every revolution of the armature in the case we are considering, or, generally, six times per cycle.—A. P. Y.

Answer to No. 802 (*awarded* 5*s.*).—Suppose, for simplicity, that the two rotary converters are exactly similar machines, with the same number of poles and the same number of turns of wire on each armature. Let Fig. 1 represent one of these rotary converters, and suppose they are bipolar; the commutator is shown outside the armature, which is ring type, whilst the three slip-rings are represented as being internal to the armature winding, and are connected to three equidistant points in the armature winding. Since both machines are run off the same source of supply, and are run in synchronism with the generators, the currents in the coils of one armature will be in phase with the currents in the corresponding coils of the other armature both in magnitude and direction, so that at any instant the electrical state of every coil in one armature is exactly similar to that in the other.

Referring to Fig. 1, it will be seen that at the instant the commutator segment which is connected to slip-ring, A, is under the positive brush, the current in phase A will be a maximum and have a positive direction, so that at this particular instant the positive brush of the rotary converter is being supplied direct from the alternating line wire. This

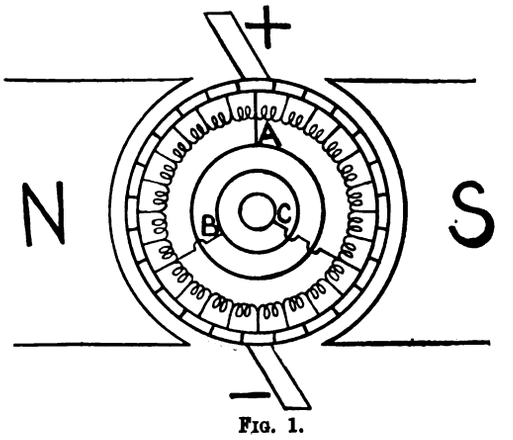

FIG. 1.

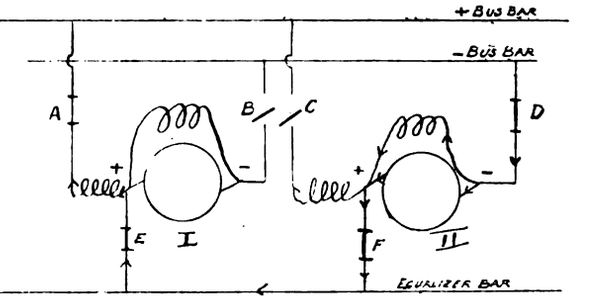
also occurs at the same instant in the other rotary converter, and is exactly the same as supplying the positive 'bus bar with two wires in parallel from one generator. This also occurs when the commutator segments connected to slip-ring B and C respectively are under the positive brush, and in the intermediate stages the conditions may be considered similar, because, though not being fed by one particular phase, the positive brush is collecting current which is the resultant of two phases, and equal to the maximum supplied by one. At the negative brush the same action takes place but in the opposite direction, so that the direct-current 'bus-bars may be considered as being supplied from one source with two positive and two negative leads in parallel. Now by cutting out one of each of these leads, it matters not which one, a load may be taken off the 'bus bars as before, so that in the case of the two rotary converters the positive of one and the negative of the other may easily supply the load.—B. W.

Answer to No. 802 (*awarded* 5*s.*).—The result stated in this query is, at first sight, rather astonishing, but after a slight inspection the cause at once appears. The accompanying sketch shows the direct-current side of the rotary converts as they would be connected up. It will be noticed that each converter has a series and a shunt field. In addition to closing the + switch, A, of one rotary and the negative, D, of the other, the equalising switches are also



closed; if they were open, *no* load would be taken by the rotaries. An electric circuit can now be traced from the − 'bus bar to the +, as shown by the arrows, through the armature and shunt of No. II. rotary, equalising switch, F, through the equaliser bar to switch, E, thence through series winding of rotary No. I., through + switch A to the + 'bus bar. It will be seen that rotary No. II. only delivers current as a shunt machine, its series coil being cut out. No. I. rotary is driven from the alternating side, but does not at all contribute to the (load) power of the 'bus bars.—N.

Question No. 803.—A Parsons two-phase alternator, 25 kw., is excited from a small exciter carried on an extension of the main shaft. The alternator field is connected directly across the exciter brushes through a Weston type of ammeter placed on the switchboard. There is a switch and regulating resistance in the exciter field. When the machine was started up, the current was in, say, the positive

Digitized by Google

direction round the alternator field, as shown by the ammeter, which read properly. When the exciter field switch was opened and closed again, the current round the alternator field was reversed, as shown by the ammeter reading the wrong way. On testing it was found that every time the exciter switch was opened the current round the alternator field was reversed, the ammeter reading first right, then wrong, and so on apparently indefinitely. What is the cause of this?

Answer to No. 803 (*awarded 7s. 6d.*).—The effect noticed is due to the combined action of the self-induction of the alternator field winding and the armature reaction of the exciter. As soon as the exciter field switch is opened the voltage generated at the exciter brushes rapidly falls to zero as the exciter flux dies down, but this does not involve the equally rapid falling off of the alternator exciting current, for as soon as the alternator flux begins to drop a voltage of self-induction is set up in the alternator exciting winding owing to the unlooping of some of the flux looped with this winding. This voltage, in accordance with Lenz's law, is always in a direction tending to oppose the change to which it is due—*i.e.*, in this case the self-induction voltage tends to maintain the alternator exciting current at its original value. The net result is that the alternator exciting current and the alternator flux do fall off, but much less rapidly than if no self-induction were present, so that by the time the flux of the exciter has died down to zero there is still a large proportion of the alternator exciting current passing through the exciter armature and the alternator field winding.

Now, the tendency of the armature reaction of a dynamo armature with the usual forward brush lead is to reverse the polarity of the magnets. In normal work this tendency is, of course, overpowered by the field excitation, but in the case in question the exciter field excitation is zero at a time when there is still a considerable current in the exciter armature, so that the armature back ampere-turns are in a position to reverse the exciter polarity during the few seconds which elapse between the breaking of the exciter field circuit and the dying down of the exciter armature current to zero.

The reversed poles produced are probably quite weak, but, since the polarity with which a self-exciting dynamo excites itself simply depends on the polarity of the residual magnetism, however small, existing in the magnets when the exciting circuit is closed, it is easy to see that the next time the exciter is used the brush which was positive will become the negative one, and *vice versâ*, just as described. The reversal can be avoided (1) by giving the exciter brushes a slight *backward* lead for a few minutes immediately after breaking the exciter field circuit; or (2) by breaking the alternator field winding in place of the exciter field winding. This latter method would necessitate the employment of a field-breaking resistance, across which the alternator field would be connected just before connection with the exciter is

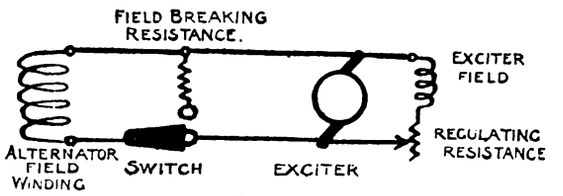


FIG. 1.

broken (see Fig. 1), in order to avoid an excessive rise of voltage due to the self-induction of the alternator field. Thus, if the field-breaking resistance were made equal to the resistance of the alternator field winding, the voltage could never rise to more than double the normal, however suddenly the switch might be opened.—Q.

Answer to No. 803 (*awarded 7s. 6d.*).—The cause of the main alternator field reversing is owing to the exciter field being reversed in the following way. Fig. 1 will show the polarity of the magnetic field due to the armature when running in the given direction, and it will be seen that part of the armature field tends to induce opposite polarity in the field magnets, as shown by the small letters on field magnet, whilst the other part has practically no direct effect on the poles. These first are within the two vertical lines, and are known as the demagnetising or back ampere turns, and are what we shall have to consider. From first principles we know that when a current is stopped in an inductive circuit, a current is induced that will tend to help the current to continue flowing. The effect of breaking the exciter field is to stop the current flowing round the alternator field, and, therefore, a sudden heavy current will be set up in the same direction as the generated current through the exciter armature. When the exciter field drops to zero there will be a fairly strong magnetic field due to this current flowing through the armature, which will induce opposite polarity in the exciter field magnets,

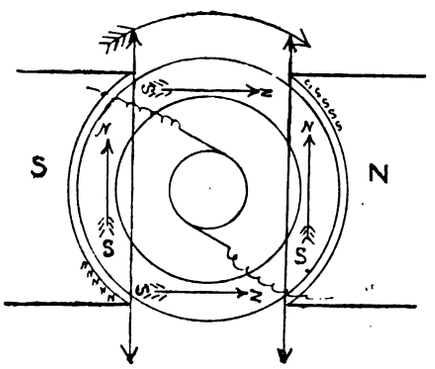

FIG. 1.

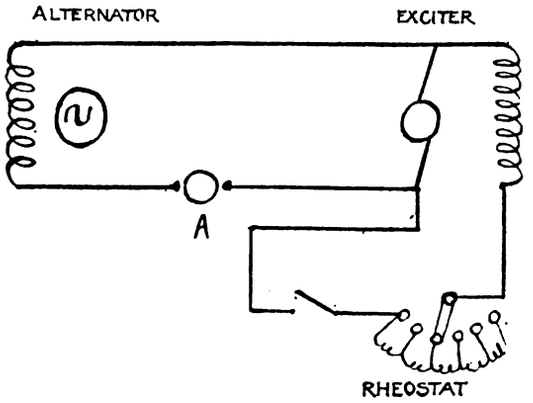
as shown in Fig. 1. Therefore, when the exciter is again started, the direction of current through the ammeter will be reversed.—A. W.

Answer to No 803 (*awarded 5s.*).—In this case it is evident that the trouble is caused by the reversal of the polarity of the small exciter. Referring to the diagram, suppose the



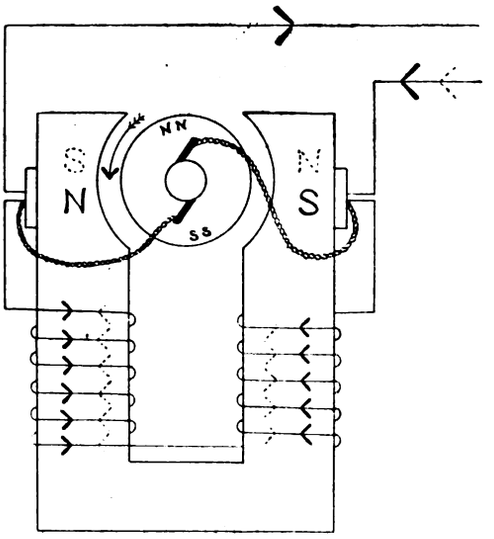
alternator to be running fully excited, and the exciter field switch to be suddenly opened. The current flowing round the field coils of the alternator cannot be instantly stopped, owing to the inductive nature of the circuit, but will tend to rise momentarily above its former value, according to the well-known principles of self-induction. Thus a current will continue to flow round the alternator field and through the exciter armature for some seconds, depending on the time constant of the field coils, and gradually falling to zero value. This current, it should be noted, will be in the same direction as before, and will produce a field in the exciter which will oppose that due to its own field coils. But since these coils are now unexcited, there remain only the residual magnetism in the iron, and this will be overpowered and its polarity reversed, with the result that when the field switch is again closed the machine will commence to build up in the opposite direction, and its poles will have changed, so that current will now flow round the alternator field in the opposite direction, as stated in the question, and the process will be repeated every time the exciter switch is opened.

The remedy, if one is needed, is to place a switch in the alternator field circuit, and to open this before the exciter field switch. The current may first be reduced as low as possible by means of the rheostat in the exciter field, and the switch should preferably be of the type which places a non-inductive resistance in circuit at the moment of breaking. A case somewhat similar to the above which came before the writer's notice, where current

Digitized by Google

was led in at the brushes of a dynamo in order to test the armature, and on afterwards starting up the machine and proceeding to parallel it with others, it was found to have had its polarity reversed. It is also quite a common occurrence with all self-exciting shunt dynamos after a heavy short-circuit.—S.

Answer to No. 803 (*awarded* 5*s.*).—The polarity of the exciting dynamo is reversed each time the magnetising circuit is opened. When a current is flowing in a circuit and the circuit is suddenly opened, a temporary rush of current tends to flow in the same direction as that of the original current before the circuit was broken. This is an instance of Lenz's law. With a shunt dynamo a current returning in the opposite direction to the normal flow *strengthens* the field, but in this case, on breaking, the current tends to flow in the same direction as the normal; the result is, therefore, that the field is *weakened* while the armature polarity is strengthened. The effect of this two-fold action on the magnetic system of the exciting dynamo is then a reversal of its polarity. This will naturally take place each time the switch is opened when on load. A remedy would be to let the exciting current fall off before breaking the circuit; for instance, the speed should be considerably reduced before the switch is opened. It may also be possible to introduce sufficient resistance in the field circuit of the exciting dynamo before opening the switch, and thus prevent reversal. A few experiments will soon show how much resistance must be in circuit to



prevent this change of polarity. In the figure the full letters and arrows are intended to represent polarity and direction of current *before*, the dotted letters and arrows the polarity and direction of current *after* switch is opened. If the exciting dynamo is given much lead to the brushes, the polarity will be the more easily reversed.—M. M.

Answer to No. 803 (*awarded* 5*s.*).—In considering this question, first take the case of an alternator having a relatively large number of ampere-turns in the field circuit. If the field is fully excited and the circuit afterwards broken sharply, there would be a rise of pressure across the terminals of the magnet windings. This is caused by the lines of force falling and cutting the windings on the fields, the resultant E.M.F. being in the same direction as that previously applied, but of much greater magnitude; in some cases it may rise to millions of volts, and where no non-inductive resistance has been installed to take up the discharge a breakdown of the insulation has resulted. As the alternator field windings of the turbine set are connected directly across the exciter brushes, the armature being of very low resistance, and having comparatively few turns, it would take up the discharge from the alternator field after the exciter field circuit had been broken, but being of *too low a resistance* for that purpose, an enormous rush of current from the alternator fields to the exciter armature would be the result. This current being in the same direction as that previously supplied by the exciter, the armature would momentarily develop a field opposed to and more powerful than the residual field retained by the exciter magnets, the result being a reversal of the residual field, which would account for the alternator field current being alternately in opposite directions. If the turbine set was shut down before the exciter field switch was opened, it would allow the fields of the two machines to die down gradually, and the alternator field current would in all probability be found to be in the same direction when next the set was started up.—CLAUDE H. KLYNE.

Question No. 804.—I am employed at a paper mill, and frequently receive complaints from the printers about electricity in the paper. I have tried several experiments with it, but without success. What is the best method of reducing or preventing the effects complained of?

Answer to No. 804 (*awarded* 7*s.* 6*d.*).—Undoubtedly frictional electricity is the cause of the trouble. I was installing a dynamo several years ago, and it was driven by means of a leather belt from a wooden driving wheel. Passing close to the belt whilst the machine was running one day I was astonished to see a spark quite two or three inches long jump from the belt into my arm. The length of the spark showed that it was not a case of leakage from the machine, so I concluded that it was frictional electricity generated by the slipping of the belt on the wooden pulley above. I noticed that the portion of belt coming from the wooden pulley down on to the iron pulley of the machine was highly charged, but that the ascending portion of the belt had no charge whatever, showing that the electricity had escaped to earth through the iron pulley. Since then I have several times come across similar cases.

In the case mentioned by "J. W." the electricity is caused by the friction of the paper on a roller, or set of rollers. The annoyance to the men may be stopped in this way. Get a long strip of sheet tin, the width of the paper, and cut notches in it right along one edge so as to form a series of sharp points. Place this close to the paper, and connect the tin by a wire to earth. After the paper has passed these metal points, it will be found to have no charge left in it. To find the best place to fix this arrangement start where the paper leaves the machine, and test whether it is charged by holding the knuckle close to the paper. Work backwards until the spot where the electricity originates is located, and put the row of points just after the paper has left this spot. If the sparks cause discomfort, make the test by means of an electroscope, where the gold leaves fall together will be the point required. It would be an advantage to connect the framework of the machine to earth also. If "J. W." follows out these suggestions, I am confident that no more trouble will be experienced.—RESEARCH.

Answer to No. 804 (*awarded* 5*s.*).—Some years ago the writer had a similar experience, although it did not cause any trouble, with rolls of cloth intended for waterproofing. The cloth appeared to get charged, like one occasionally finds machine belts that are in a dry situation. "J. W." might try touching the paper with a series of metallic brushes just before folding or rolling, these brushes being connected to earth. Paper being an insulator, the brushes should, if possible, make contact with the whole surface in order to completely discharge the paper. It will sometimes be found that the paper patterns supplied with periodicals devoted to the art of dressmaking are charged sufficiently to be rather troublesome. If these patterns are held in the hand and stroked with an earthed knife blade, they will become completely discharged, and thus lose the tendency to stick together. Had there been more data given in the question, more explicit suggestions might have been offered as to the arrangement of an earthing device or devices. The effect of a static charge of electricity causes trouble in various cases—take, for instance, the wet-plate process of photography. After polishing a glass plate preparatory to coating it with collodion, it is as well to discharge the plate before pouring on the collodion. Evidently, the querist will have to prevent friction on the paper as much as possible, and devise some arrangement by which if the paper becomes charged it may be neutralised.—M. M.

[Other replies to Question No. 804 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

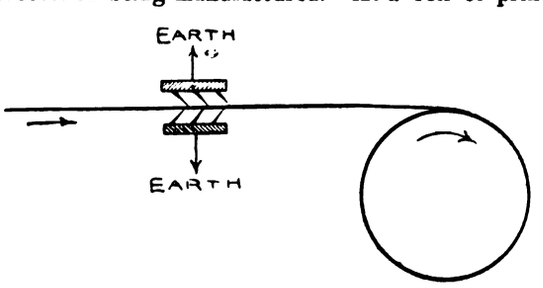
812. The owners of an isolated low-tension direct-current lighting and power installation in the colonies, supplying current to about 50 110-volt motors, varying in power from 1 h.p. to 55 h.p., are anxious to establish a repair shop on the premises, equipped with the necessary plant to effectually carry out all winding and repairs due to breakdowns and ordinary wear and tear. The motors are all of the four-pole type by various British manufacturers. Describe the most modern appliances for this class of work, with special reference to the possibility of manufacturing commutators at a reasonable outlay.—G. F.

813. A works is supplied with current from a power station with continuous current on the three-wire system, with 500 volts between the outers. It is required to split this up further at the works, for the purpose of speed regulation of the motors driving the various machines, by means of "shunt" or "shunt" and "armature" regulation combined. The voltages proposed are as follows: between outers 500 volts, between outer and middle wire 250 volts, between middle and intermediates 60 volts, between intermediates and outers 180 volts, which would enable the motors to be supplied with voltages of 500, 310, 250, 180, and 60. Show clearly how this could best be done. Further, would it be to the advantage of the company owning the works to put down their own generating plant for lighting and power, and, if so, what arrangement of generator would be best to adopt, without the use of balancers?—MOTOR-CONTROL.

ANSWERS.

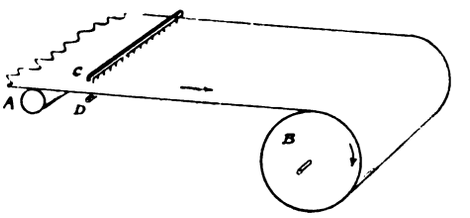
Question No. 804.—I am employed at a paper mill, and frequently receive complaints from the printers about electricity in the paper. I have tried several experiments with it, but without success. What is the best method of reducing or preventing the effects complained of?

Answer to No. 804 (*awarded 7s. 6d.*).—What I understand by the printers finding electricity in the paper is that they find the paper has an electrostatic charge of electricity, which, no doubt, is due to the tremendous friction which the surface of the paper is subjected to in the process of being manufactured. As a roll of printer's



paper is of a considerable length, it acts as a condenser of large capacity, and, therefore, takes a heavy charge, and being a very good insulator will retain the charge for a considerable period. The action of points on an electrostatically-charged body is well known, and I think a good method of discharging the paper would be to have, both above and below the paper before running on to the roll, two metallic bars, into which are fixed a large number of points or needles, these, of course, extending the whole breadth of the paper, and having each of these connected to earth, as shown in the accompanying sketch. The points would require to be sloped slightly in the direction in which the paper is travelling, to keep from tearing it.—B. W.

Answer to No. 804 (*awarded 7s. 6d.*).—The effect described by "J. W." as "electricity in the paper" is probably due to the friction to which the paper is subjected during its passage through the machines. Although no details are given in the question as to the treatment of the paper, it is probable that it finally passes in the form of a long strip over or under wooden or metal rollers. Some of these rollers may act as drivers and others merely as guides. The passage of the paper over these rollers would cause the paper and the roller to be oppositely electrified by friction. The same effect is often noticed on a leather belt driving a metal pulley, in which case sparks may often be drawn on to the hand held near the edge of the belt. To neutralise the charge on the paper, the frame of the machine should first be connected to a water-pipe or gas-pipe (preferably the former) by means of a wire. This



will "earth" the machine. In the figure A is the last roller on the machine which the paper touches before it is wound on the roll, B. C and D represent two metal combs, one above and the other below the surface of the paper. They consist each of a strip of metal with a number of points about 2in. apart arranged along their length. They should be fixed metallically to the frame of the machine as near the last roller as possible, as the paper would probably have only a slight up and down vibratory movement there. The points should be directed towards the surface of the paper in both cases. The combs could be quickly made for the test by soldering ordinary pins to an iron or brass strip. If this is not found satisfactory, the following arrangement might be tried: Paper, in passing over wooden rollers, would become negatively electrified, but in passing over metal rollers the paper would become positively electrified. Temporary wooden rollers might be fixed up above and below the paper just before it is rolled on B. If the electrical charge on the paper is increased, then metal rollers should be substituted. It is really a matter for experiment. Pith balls would be the quickest way of getting an idea of the relative charge in the two cases.—S. L.

Answer to No. 804 (*awarded 5s.*).—Some years ago I was for about 18 months working in a paper mill, and had much the same experience as "J. W." describes. The cause of this electrification seems to lie in the calenders. After the paper is made it is passed through a series of perfectly smooth steel rolls, which are all driven at a slightly different speed. Hence, as the paper passes between these rolls, it is subjected to a sort of rubbing action, which gives it a gloss and finish. It seems to be this rubbing in the calenders which causes this electrification, and this is difficult to get rid of. If the paper were damped, that might get rid of this objectionable effect, but then that would damage the paper and destroy the gloss. I have many a time seen sparks some inches long drawn from paper as it has left the calenders. In the case I am referring to, the difficulty was got over by suspending a horizontal copper wire from above so that it rested on and rubbed over the surface of the paper as it left the calenders before being rolled up. This wire was well earthed, and proved a great boon. Of course, this was rather a primitive method, and perhaps it would be better if the paper after leaving the calenders could be passed over one or two small rolls above and below it, which should, of course, be very well earthed. Of course, these rolls should be arranged so that although the paper passes over them it is not subjected to any more rubbing or

Digitized by Google

friction, as in that case not much good will have been done. I think if "J. W." tries this method, he will have no more complaints from the printers.—E. R. ALEXANDER.

Question No. 805.—Show by comparative figures the advantage of using laminated poles compared with solid ones for direct-current machines. Is there any real gain in the use of the former, when air-gap is not less than half the width of slot ?

Answer to No. 805 (*awarded* 10*s.*).—Experiment has certainly shown that lamination of the pole-pieces, if carefully carried out, does reduce the iron losses of a machine even when the ratio $\frac{\text{slot opening}}{\text{air-gap}}$ is as small as 2, though the saving effected increases rapidly with this ratio. Comparative tests on the same machine with and without laminated pole-pieces are difficult to get at, but the question has often been investigated analytically, and the following rules deduced by R. Rüdenberg in a recent article (*Elektrotechnische Zeitschrift*, Feb. 23, 1905) enable, at least, an approximate calculation of the pole-piece eddy-current losses with solid poles to be made in any given case. This writer shows that, on the assumption that the flux density on the pole-face at a given instant varies from a minimum opposite the centre of a slot to a maximum opposite the centre of the next tooth, in accordance with a sine law (see

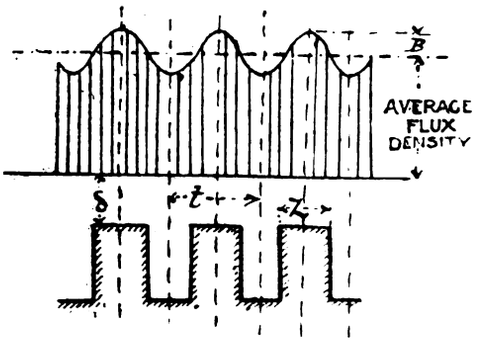


FIG. 1.

Fig. 1), the following expression holds good for solid-iron pole-pieces :

$$W = V^{1.5} \times B^2 \times \sqrt{\frac{t}{S \times \mu}} \times 4 \times 10^{-9},$$

where W = pole-piece eddy-current loss in watts per square centimetre of pole-face ;
V = peripheral speed of armature surface in centimetres per second ;
B = half the difference in flux density (C.G.S. lines per square centimetre) between points of minimum density (opposite slots) and points of maximum density (opposite teeth)—*i.e.*, the amplitude of the flux variations from the average (see Fig. 1) ;
t = slot pitch—*i.e.*, distance between the centre of one slot and the centre of the next, in centimetres (see Fig. 1) ;
S = specific resistance of pole-piece material in absolute units per centimetre cube = approximately 10^4 for wrought iron or steel and 10^5 for cast iron ;
μ = average permeability of the pole-piece material. This cannot be accurately determined, but may be estimated from the maximum and minimum pole-piece flux densities, and is usually about 1,000 for wrought-iron pole-pieces.

The value of B, as compared with the average air gap flux density, depends on the ratio of the slot opening to the air-gap length, and may be arrived at by means of any of the empirical rules used for deciding the effect of the slots on the air-gap resistance of slotted machines. The following simple rule due to Prof. Arnold, for instance, will give the required value of B directly :

$$B = \text{average flux density in air-gap} \times \left(\frac{t}{Z \times (X + \delta)} - 1\right),$$

where "average flux density" =

$$\frac{\text{total flux per pole in C.G.S. lines}}{\text{area of one pole-face in square centimetres}} ;$$

t = slot pitch, as above ;
Z = width of tooth top in centimetres (see Fig. 1) ;
δ = single air-gap in centimetres (see Fig. 1) ;
X = a variable depending on the ratio of slot opening to air-gap, and obtainable from the curve in Fig. 2.

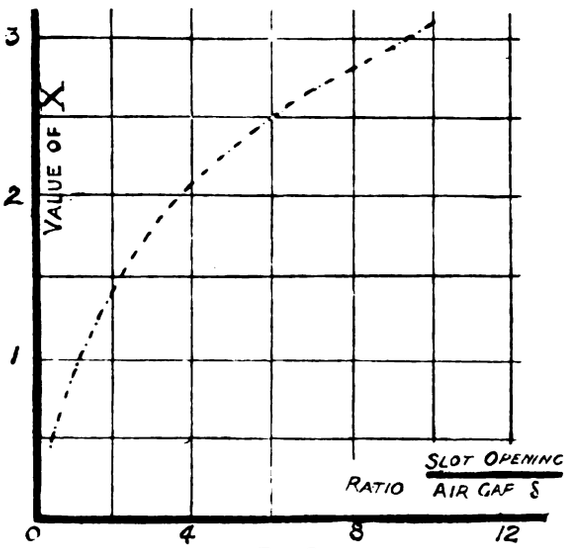

FIG. 2.

An example will help to make the method of application clear. A certain dynamo gives an output of 14 kw. at 1,000 r.p.m. It has an armature 12in. in diameter and 5in. long with 40 slots, each ·3in. wide. It has four solid cast-steel poles, with a pole-face area of 30 square inches each. The single air-gap (to the top of the teeth) is $\frac{1}{8}$in. Total flux per pole = $1{\cdot}4 \times 10^6$ C.G.S. lines. From these particulars the following values are obtained :

$$v = \frac{\pi \times 12 \times 1{,}000}{60} \times 2{\cdot}54 = 1{,}600\text{cm. per second.}$$

$$\text{Ratio } \frac{\text{slot opening}}{\text{air-gap}} = \frac{{\cdot}3}{{\cdot}125} = 2{\cdot}4. \quad \therefore X = 1{\cdot}5 \text{ approximate.}$$

$$t = \frac{12 \times \pi \times 2{\cdot}54}{40} = 2{\cdot}4\text{cm.} \quad Z = 2{\cdot}4 - ({\cdot}3 \times 2{\cdot}54) = 1{\cdot}64\text{cm.}$$

$$\delta = {\cdot}125 \times 2{\cdot}54 = {\cdot}32\text{cm.}$$

$$B = \frac{1{\cdot}4 \times 10^6}{30 \times 6{\cdot}45} \times \left(\frac{2{\cdot}4}{1{\cdot}64 + (1{\cdot}5 \times {\cdot}32)} - 1\right) = 1{,}070 \text{ C.G.S.}$$

lines per square centimetre.

S may be taken as 10^4, and μ as 1,000. Then,

$$W = 1{,}600^{1.5} \times 1{,}070^2 \times \sqrt{\frac{2{\cdot}4}{10^4 \times 10^3}} \times 4 \times 10^{-9}$$

$$= 64{,}000 \times 1{\cdot}15 \times 10^6 \times \frac{1{\cdot}55}{100 \times 31{\cdot}6} \times 4 \times 10^{-9}$$

$$= {\cdot}145 \text{ watts per square centimetre.}$$

Total eddy-current loss = ·145 × 30 × 6·45 × 4 = 112 watts = ·8 per cent of full load.

If the pole-pieces were thoroughly laminated to a depth of an inch or so, most of this loss would be avoided. The plane of the laminations must be parallel to the plane of rotation and not parallel to the length of the armature, as the latter arrangement would permit the eddy currents to complete their circuits through the back of the poles, and would scarcely diminish the losses at all. It is, further, of great importance that not even a thin skin of solid metal should be left at the pole-face, for the whole of the eddy-currents are in any case confined to a thickness of only one or two millimetres just at the surface. These currents, in fact, themselves counteract the flux changes which produce them, and cause a practically uniform flux distribution to be attained at a very small distance within the solid pole-face. The depth, d in centimetres, within the pole-face at which the flux fluctuations are reduced to one-hundredth of their surface value (and beyond which the eddy-current loss is, therefore, quite negligible) may be found by the expression :

$$d = {\cdot}73 \sqrt{\frac{s \cdot t}{v \cdot \mu}}.$$

Digitized by Google

In the above example $d = 73\sqrt{\frac{10^4 \times 2{\cdot}4}{1{,}600 \times 10^3}} = {\cdot}09$cm., or just under 1mm.

If, therefore, quite a thin skin of solid metal exists on the pole-face, through machining or otherwise, most of the good effect of the laminations will disappear.

When the lamination is complete, the flux fluctuations penetrate to a considerably greater depth (probably to a depth equal to two or three times the width of the slot opening), and this gives rise to a certain amount of hysteresis loss. Experiment has shown, however, that this loss is not nearly so great as the eddy-current loss which it replaces.—Q.

Answer to No. 805 (*awarded* 7*s.* 6*d.*).—The advantage or otherwise of using laminated poles for direct-current machines must be considered from two points of view—first, as regards the limb itself, and, second, as regards the pole-face. By using stampings for the limbs the use of the best possible material is assured, and, what is even more important, material whose uniform permeability can be relied on. It is desirable to run the limbs at a fairly high density in order to get a short length of mean turn for the coils, but this is a dangerous practice if the limbs are of cast steel, as with a bad casting it may be impossible to get the desired flux without overheating the field coils. The yoke can be run at a lower density, and a variation of its permeability will not be so serious. Laminated poles also lend themselves easily to methods reducing the field distortion by armature reaction, as in the Johnson-Lundell dynamos (see Fig. 1). In these machines the

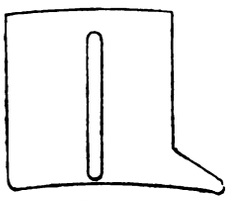

FIG. 1.

forward half of the limb is highly saturated at no load, as it supplies an air-gap of more than half the total area, and this prevents excessive densities under the trailing tip when the load comes on. Another point in favour of laminated poles may be mentioned—namely, that they respond more rapidly to a change of magnetising current. The eddy currents generated in a solid pole tend to prevent any change of flux. This is only of importance is some special machines, such as battery boosters. On the other hand, a laminated pole cannot, of course, be made circular, which is the most economical section as regards weight of field wire. A square limb has a longer periphery than a circular one of the same area in the ratio of 4 : 3·55, and the weights of wire required are in the same ratio. A circular coil is also cheaper to wind and insulate than a square one. As regards the pole-faces, if these are not laminated the air-gap should be not less than five-eighths of the width of slot In a given machine the eddy currents are proportional to the square of the peripheral velocity and to the square of the induction. With fairly high values of these the writer has known very marked heating of pole-shoes to result from reducing the air-gap from five-eighths to one-half the slot width.

Although it is quite possible to design a line of machines with this ratio of slot-gap, it is very convenient to be able to shorten the gap considerably in special cases. Also the laminated pole-shoe made by riveting punchings together is cheaper than any other form, the turning inside and outside of cast-iron pole-shoes being a very expensive piece of work.—W.

Answer to No. 805 (*awarded* 5*s*).—The use of laminated poles or pole-shoes with armatures having open slots prevents the formation of eddy currents in the pole-face. These eddy currents are caused by the uneven distribution of magnetic lines over the pole-face, due to the armature teeth, as shown in Fig. 1. These gaps in the magnetic lines becomes very marked when the air-gap is small, and almost disappear when the air-gap is large, owing to the fringing of the lines at the corners of the teeth (see Fig. 2). In a machine having an air-gap of one-quarter slot width, the total iron losses would be approximately reduced by half by using laminated poles in place of solid ones. Without fear of eddy currents, air-gaps can be reduced to an amount limited only by the necessary mechanical clearance, which results in a saving of copper in the field windings. Apart from the question of iron losses, experiments show that not only do solid poles

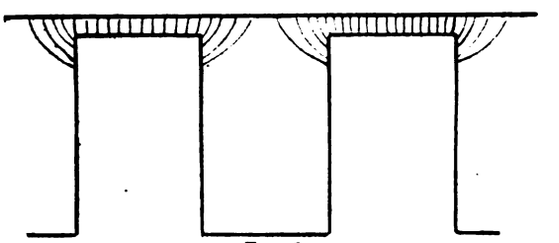

FIG. 1.

get overheated, but they radiate heat on to the armature and field windings, increasing the temperature rise of the machine throughout. Laminated poles have one disadvantage, that they cause humming unless they are built up very tightly. As to whether it is worth while using laminated poles when the air-gap is not less than half slot widths depends on the speed of the machine. The eddy-

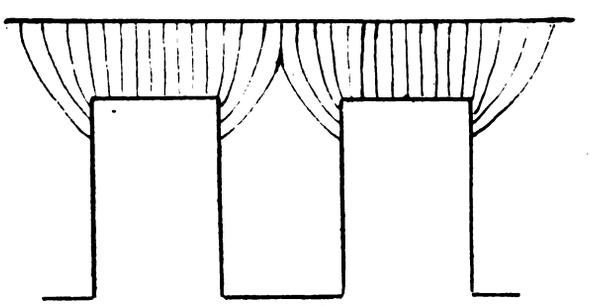

FIG. 2.

current loss is proportional to the square of the speed, so that one might say that for all high-speed machines, even with large air-gaps within reason, it is advisable to fit laminated poles.—H. O. B.

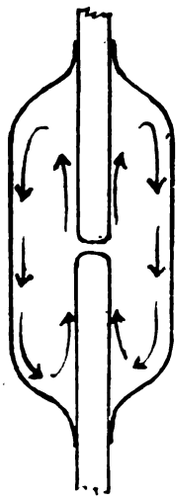
Answer to No. 805 (*awarded* 5*s*).—It is extremely doubtful whether any reliable tests are available to give figures as specified in the query. In any case figures would have to be modified for each particular machine, and also for every alteration in the load on the machine. Speaking generally, it does not appear to be worth while to laminate the field magnets of direct-current dynamos, although it is advantageous to have laminated pole-shoes. The eddy currents exist practically on the surface of the polar faces, and penetrate but little into the body of the magnets. By employing laminated poles these poles may be so shaped as to assist commutation; they may also be so arranged as to hold the magnet windings in position. As to the employment of laminated poles, a great deal will depend on the speed of the machine; although in high-speed dynamos laminated poles might be advisable, it would certainly not pay to fit them on slow-running machines. A large air-gap, with small and closely spaced teeth in the core, reduce eddy-current losses to a minimum, while a small air-gap with wide teeth have an opposite effect. In the number of this journal for Dec. 5, 1902, there is a paper on eddy currents by Dr. Thornton. In that paper the advantage of good workmanship is pointed out as an antidote to eddy current losses. It will therefore be seen that there are many points from which the question can be approached.—M. M.

Question No. 806.—At a power station they use several alternating arc lamps, B.T.H. enclosed type in parallel on a 220-volt circuit, with a choking coil in series. The carbons used are not consumed equally unless one of them is cored and the other solid. What is the reason they do not burn in equal quantities?

Answer to No. 806 (*awarded* 7*s.* 6*d.*).—The electrical properties of the circuit are the same for the forward as for the backward pulse of the alternating current, so that some physical explanation must be looked for. The most probable is the presence of convection currents in the enclosed space surrounding the carbons. In a direct-current arc

Digitized by Google

lamp the temperature of the thicker carbon which is cored and forms the crater is much higher than that of the smaller one. The hotter carbon burns away and disintegrates at a quicker rate than the other, so that carbons of equal diameters cannot be used. Referring to the



diagram, it will be seen that the convection currents, indicated by the small arrows, and which are caused by the rising of the heated gas from the neighbourhood of the arc, tend to heat the upper carbon and cool the lower one. This infers that it is the upper carbon which wastes away more rapidly. The cooling effect due to the convection currents in gases is sometimes very considerable, and has been tested with platinum wires heated to incandescence in a space which could either be a vacuum or filled with different gases. But a secondary effect with uncored carbons, due to the wandering nature of the alternating arc, is likely to be much more important than the purely cooling or heating effects of the convection currents. As the arc is wandering round the edges it will be driven up closer to the upper carbon, heating it more than the lower one, with consequent greater waste. If one carbon be cored, the arc is kept more central, and, therefore, out of the way of the convection currents. The latter will also not be so great or have such a marked influence. The softer core is a place of easier disintegration and provides a starting place for the arc.—E. S.

Answer to No. 806 (*awarded 7s. 6d.*).—In the question "H. W. C." does not mention whether it is the upper or the lower carbon that is consumed the quicker, or how much quicker one burns than the other. Now, in all alternating-current arc lamps the upper carbon wastes about 8 per cent. faster than the lower, unless the carbons are in a horizontal position, when they will burn evenly. This evidently proves that it is the upper carbons of the lamps in question that are burned the quickest. The reason for the lower carbon lasting so much longer than the upper is that small particles of carbon are continually falling from the upper and adhere to the lower. There is no advantage in using a solid carbon at the top and a cored one at the bottom, as the cored one only burns away more quickly, owing to the core being of a softer nature. The above may be proved by experiment in the following manner. Fit up one of the lamps with the ordinary solid carbons, and allow it to burn for a few hours in a horizontal position, taking care to measure the carbons before insertion. After it has been burning for a convenient time, take out carbons and again measure them. This will give the amount of carbon consumed in a measured time, and should in this case be the same for each carbon. Now fit up lamp with one cored and one solid carbon, and proceed as before (the lamp still remaining horizontal). This time it will be noticed that the cored carbon has burned very much faster than the solid one in the same amount of time, thus showing a disadvantage in using a cored carbon with a solid one. It will also be noticed that if the lamps have burned for the same length of time in each case, all the solid carbons will have lost practically the same length.—P. S.

Answer to No. 806 (*awarded* 5*s.*).—Theoretically speaking, the carbons in an alternating-current arc lamp should be consumed at equal rates, because, as the direction of the current changes regularly, the amount of carbon particles leaving one carbon during the first part of the cycle should equal the amount leaving the other during the second part of the cycle. There is, however, a consideration which is met with in practice which causes the top carbon to be consumed at a higher rate than the bottom carbon. This is that the flame of the arc plays mostly on the top carbon no matter in which direction the current is flowing. This is, of course, a peculiarity of all flames—that, no matter in what manner they are burning, they always tend to travel upwards, due, of course, to the fact that the flame is lighter in weight than the surrounding air. The result is that with the flame playing on the top carbon more than on the bottom one, the top carbon is consumed at a higher rate. The remedy applied in the question is that of coring the carbons. The core is softer than the outside of the carbon, and, therefore, this carbon is consumed at a higher rate. This difference of consumption mentioned in the question is not by any means as great as that met with in direct-current arc lamps, and I should hardly have thought it worth while to core the bottom carbon unless the lamps were run a long time without being attended to.—ERNEST P. HOLLIS.

Answer to No. 806 (*awarded* 5*s.*).—The question does not state which of the carbons, upper or lower, is cored and which solid. It is, however, supposed in answering this question that the upper is solid and the lower cored, the upper being the one which tends to burn away faster. A possible explanation is that a brisk circulation of the heated gases takes place inside the enclosing globe, the gases rising around the carbons and descending again close to the globe. The upper carbon would thus tend to be kept at a higher temperature, and, in consequence, deteriorate and oxidise (to the limited extent occurring in enclosed lamps) and volatilise at a faster rate than the other. Mr. Duddell has shown that an ordinary direct-current arc, either open or enclosed, between solid carbons, if shunted by a condenser in series with a self-induction, converts part of the direct current into an alternating one flowing in the local circuit, consisting of the condenser, self-induction, and arc. The writer suggests that in an alternating current arc the reverse operation may occur under some circumstances, part of the current in one direction being suppressed and augmented in the other direction, the unidirectional current being superimposed on the alternating current of the circuit, causing the carbons to burn unequally. A sensitive *moving-coil direct-current* ammeter inserted in the circuit would show the presence of the rectified current, if any.—W. J. L

Answer to No. 806 (*awarded* 5*s.*).—The phenomenon of the greater consumption of the upper carbon in an alternating-current arc lamp would appear to be due to the fact that, owing to the position of this carbon above the arc, a greater length of it is of necessity at a somewhat higher temperature than the lower carbon in consequence of heated particles of carbon in the "mist" being carried upwards by the air currents. This would make the upper carbon in a favourable condition for more rapid consumption than the lower carbon. The difference in consumption of the two carbons, both of the same quality and diameter, is about 8 per cent. generally. If the carbons are placed horizontally, the consumption is the same for both. When cored and solid carbons are used, it is usual to place the former at the top. The consumption is then equal on both carbons. Mr. Duddell has shown that the cores of carbons have generally a higher specific resistance than that of the carbon which surrounds them. Cored carbons give a steadier light, and require a lower voltage to maintain the arc. With the upper carbon cored the light obtained from each unit of surface is diminished, and this corresponds to a lower temperature. This would mean that the temperature of the upper cored carbon and the lower solid carbon would be more nearly equal, and correspond to equality in consumption.—S. L.

Supplement to "The Electrical Engineer,"
SEPTEMBER 15, 1905.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS

814. In the brake equipment of tramway rolling-stock, the present tendency is to put the brake blocks below the centre of wheel. Why is this so? And if the brake has more power in the lower position, explain the reason.—INTERESTED.

815 I want to make a solenoid that will operate the starting lever of a clock mechanism. The lever has to be pulled through a distance of ⅜in.; pull required, 1½lb. Is it practicable to make such a solenoid to operate from a few cells? Solenoid and plunger to be kept as small as possible. The starting lever could, perhaps, be lengthened so as to reduce the pull required, but, of course, the distance it would have to be moved through would be increased proportionately.—SOLENOID.

ANSWERS.

Question No. 807.—In a continuous-current central station it is believed a consumer is using his current to earth. Describe the best method of detecting and locating this consumer.

Answer to No. 807 (*awarded 7s. 6d.*).—When current is flowing through the earth due to some fault, it either returns or goes out through the Board of Trade panel, depending whether it is a positive or a negative fault.

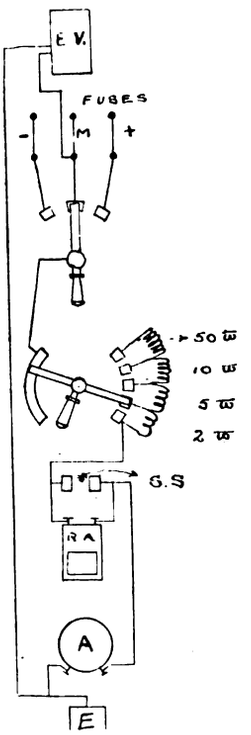

FIG. 1.

Fig. 1 shows the connections of the Board of Trade panel, by means of which any of the three mains can be put to earth through a suitable resistance depending on the size of the fault. E V is an electrostatic voltmeter connected between the middle wire and earth, and will give a good idea of the seriousness of the fault; if the fault is only due to a consumer using his current to earth, then this voltmeter will not read, as the volts have all dropped in his lamps. R A is a recording centre-zero ammeter reading 10 amperes each way, which is shunted by the switch, S S, when taking the earth readings on ammeter, A, which reads to about 70 amperes. There are two methods of locating an earth, depending whether it is a constant or intermittent one.

(1) *A Constant Earth.*—This is probably due to a fault on the mains, and too much current should not be passed through it, as it may develop into a short. To locate this, the network should be split up into two parts, so many feeders supplying each part. One part can be run on separate 'bus bars or the feeder ammeters noted to see on which part the earth is; this part is then split up again and so on until the fault is located to a length of distributor. (N B.—If the fault appears on a length of distributor which previously tested good, then test the feeders you have been using.) All the consumer's switches are then opened on this length, and if the earth is still on, disconnect this distributor and make a loop test to locate the position of the fault.

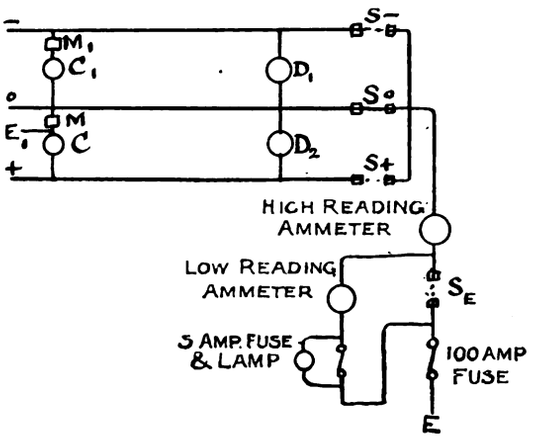
(2) *An Intermittent Earth.*—If this only comes on during lighting hours it may be assumed to be a consumer, and as the network cannot be split up on load some other method must be adopted. If it is a positive earth and the consumer is using his current to earth, then by putting the positive to earth on the Board of Trade panel the consumer's lights will go out, as both ends of his lamps are now to earth, and he will soon let the station know he has no light. If the consumer still lies low, then put the negative to earth, which will burst his lamps or blow his fuse.—H. E. T.

Answer to No. 807 (*awarded 7s 6d.*).—We will assume that the system used is the three-wire one, with the middle wire earthed only at the station, as this arrangement is by far the most common. If all the meters in use are fixed on the outers, and not on the middle wire, then the current used by the consumer will be measured by the meter whether his installation is earthed or not, unless he has cut the meter out with some cable. This would be very unlikely, as the first person to inspect the meter would detect the arrangement. If the meter is on the middle wire, he can render it useless by connecting his lamps to earth some distance from the corporation fuses, etc., and thus making detection difficult. But in this case the amount of current used would be registered on the earth leakage recorder connected to the middle wire in the station. Notice the hours that this earth leakage is recorded, as it affords a good indication of what kind of consumer he is. If he uses the current for power purposes, the leakage will show from 6 a.m. to 5 30 p.m. If for shop lighting, the likely hours are from dusk to 8 or 9 p.m., and on early closing nights it will be off; and if for private house lighting, he will use the current till late at night. It is very unlikely that he will be using it for motors, especially large ones, as he will only be able to get 200-250 volts. Three-wire stations make it a rule to only supply motors below 20 h.p. with 200 volts, so as to avoid out-of-balance troubles. Assuming that he is not a power consumer, choose a time when all motors are off and the leakage is on; get two assistants to pull the positive and negative switches out simultaneously, one feeder at a time, immediately closing them again, so as to only cause a slight blink on the lights. Carefully watch the earth ammeter needle all the time. When the feeder supplying this consumer is pulled out, the needle will go to zero momentarily. The reason why the positive and negative switches must be both pulled out at the same time is so as not to cause an out-of-balance current on the system. Suppose both feeders have 100 amperes load, and one switch only is pulled out, then there will be an out of balance of 100 amperes, which will perhaps overload the balancers. From the above observations the class of consumer will be known and the district where to look for him, so it should not take long to inspect this locality and see that all meters are connected to the outers, and have not been tampered

Digitized by Google

with. If he is a power consumer, all these consumer's meter connections must be inspected.

Another and much better method could be easily tried in most three-wire stations. The sketch shows the earth connections for the neutral wire used in many stations. Under ordinary conditions the middle switch, S_o, would be closed



connecting the middle wire to earth. A consumer, C, has his lamps connected to the positive side of the system and earth. Pull out S_o and insert S−, thus making the negative cable at earth potential. The positive cable will now be 460 volts above earth, and the consumer's fuse will blow and probably his lamps explode. He will at once send in a complaint, and thus expose himself. If he is artful, he may reinsert the fuse, get any fresh lamps required, and say nothing about the matter. Make it an expensive practice for him by earthing the negative for a moment when it is known he has his lamps on. Of course, if the consumer is on the negative side of the system, the positive must be earthed in order to burst his lamps. To make the sketch quite clear, the switch S_o is generally closed, earthing the middle wire through a small fuse. If an earth comes on either side of the system, this fuse blows, and the lamp in parallel lights up. This warns the attendant to make switch S_E, which now earths the neutral wire through a 100-ampere fuse. The consumer C has his meter, M, connected to the wrong main and earthed at E_1. The consumer C_1 has his meter, M_1, connected to the right main.

By using either of the two methods described "H. W. N." should be able to quickly stop the stealing of current from the mains.—RESEARCH.

Answer to No. 807 (*awarded 7s. 6d.*).—If the consumer is using his current directly to earth, his connections will be as shown in Fig. 1, where a tapping is taken off at A, and

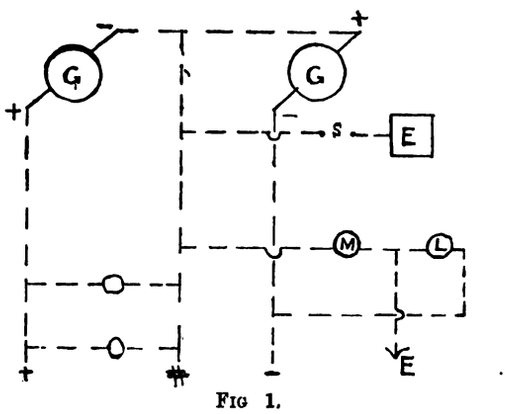


FIG 1.

so cause the current to miss the meter. A good method for testing the insulation resistance of the neutral, or outer, conductors without interrupting the supply is shown in Fig. 2, where the station battery is working in parallel with the generators, and both feeding into the network. E is the station earth-plate, connected through a switch to the neutral. A connection is also taken from the earth-plate through an ammeter to a two-way switch, and connected to three cells as shown. If the permanent earth is broken by the switch, and the two-way switch placed on contact B, the positive conductor of the positive battery will be connected to the earth-plate, and if an earth exists anywhere on the neutral a current will flow from the cells to the earth-plate, through earth into fault, and return along the neutral.

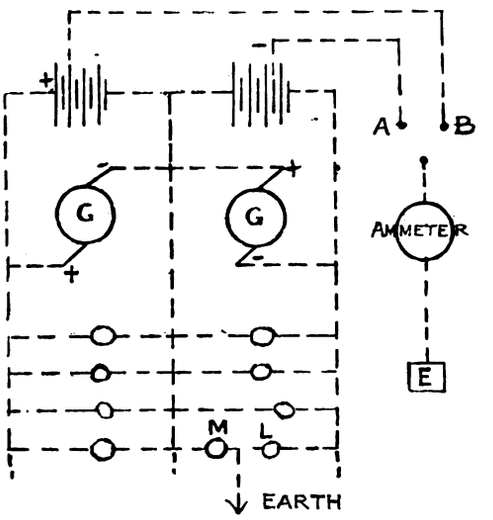

FIG. 2.

If the two-way switch is changed to contact A the same thing occurs, only the current is in the opposite direction. If an earth exists, the next step is to find it within a certain area. This can be effected very easily where there is a shunt central-zero ammeter, with a shunt between each neutral feeder, and the station neutral 'bus bar, to measure the current flowing through each neutral feeder. This test should be made when there is no likelihood of the supply altering for an hour. The permanent neutral earth at the station need not be interfered with during this test. Take readings from the ammeter and neutral feeder shunts of any current that is flowing between the neutral feeders and the station 'bus bar, and make a note of the direction of the current by central zero ammeter, then earth the negative side of the system through an ammeter and resistance, commencing with a few ohms. Fig. 3 shows the connections. The negative side is preferably earthed, for the reason that if for the purpose of testing it is necessary to put an extra strain on the insulation of either of the outers, the positive should always be in a better condition to sustain it, because the insulation resistance of the negative from earth is generally lower than positive. When the

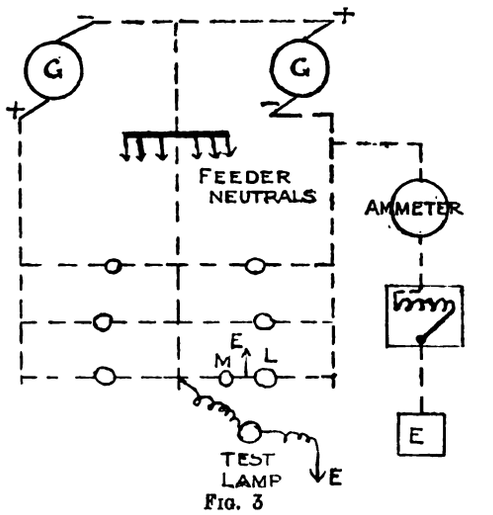

FIG. 3

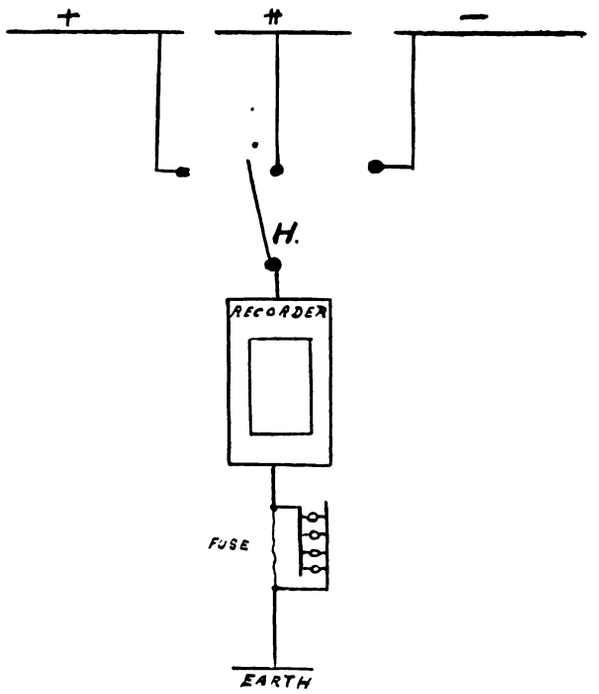
negative outer is earthed through the resistance, R, take the readings of the ammeter, A, and as quickly as possible take another set of readings of the feeder neutral-wire currents. These will be found to have increased over the previous readings, in proportion to the ratio of distance between each feeder and the faulty main. If the system is a large one, with a number of feeders in parallel on the network, it may be necessary to increase the current permitted to pass to the earth-plate through the resistance, R, but it should be kept as low as possible to prevent the con

Digitized by Google

ditions of pressure on the main altering, so that the positive conductor of the system is put to a dangerous potential from earth, the Board of Trade limit being 250 volts, and to also prevent the possibility for seriously disturbing the defective wire. Having taken the second set of readings of the feeder neutral wire, it then remains to judge the locality of the fault. After the fault has been localised to a certain district, you can then split that portion of the network into section, making tests of each section until the faulty one is discovered. When the faulty section is found, you can then proceed to find at which junction box the faulty cable is connected. This can be done by Murray's loop test or by disconnecting the supply at each junction box, and test beneath the neutral and earth with an incandescent lamp of the same voltage as the supply. If it does not light, then connect up the supply again and go to the next box and disconnect the supply and try the lamp across the neutral and earth. If it lights, then the fault is at the last box which you have previously tested. Connect up the supply again and go to the faulty box, connect your lamp to the neutral and earth, then disconnect each consumer's main which is connected to the outer feeder, and the main which, when disconnected, puts the lamp out is the faulty consumer. This would, perhaps, be the quickest way, as the resistance of consumer's wires not being the same as the feeders will cause a great deal of testing by Murray's test, which has often been discussed in this paper.—J. P. S

Answer to No. 807 (*awarded* 5*s.*).—In continuous-current stations it is customary to earth the neutral 'bus bar through a fuse, across which is connected a batch of lamps, so that in the event of either of the outers being put to earth the fuse blows; but the neutral still remains earthed through the lamps and a current will flow, the magnitude of which depend on the resistance offered by the lamps. A consumer who takes his current from one of the outers and earth is obviously fed through the earth fuse, that is provided the neutral is not earthed in any other part of the system, except at the station; in which case his current will be recorded on the earth recorder, which is in series



with the fuse, together with any other earth current. If there is reason to believe that the whole of the earth current is due to the consumer in question, and that he is not committing the offence purposely, it is possible that by dimming his lights somewhat he will come round to the station and report the matter. This can easily be done by arranging the batch of lamps joined across the earth fuse to have about the same resistance as those on the installation, then by removing the fuse the resistance will be doubled and the lamps will burn a dull red. The most satisfactory way of dealing with such troubles—in fact, I might almost say, preventing them—is to have a special switch for flashing the two outers to earth. The arrangement will be best understood by referring to the sketch; + ++ − represent the three 'bus bars. A wire is taken from each to three separate contacts on a three contact switch, while the handle, H, is joined to earth through a fuse and recording ammeter. Under ordinary conditions the switch handle is kept on the centre contact, thus earthing the neutral. If one of the outers becomes earthed, the fuse blows, and the rush of current is recorded on the recorder, and if the outer remain down to earth, the lamps will light up and remain alight until the earth is removed, when the fuse is replaced. In order to test the current between either the outers and earth, the handle, H, is switched over to the two outside contacts separately, which will put the full pressure on the insulation between earth and copper on each of the outers. By flashing over about three times a day with a fair-size fuse, it not only clears a number of small earths on consumers' premises, but also locates any trouble like that under consideration. Suppose, for instance, a consumer was taking his current between positive and earth, then, when the negative is flushed, he will obtain just double the pressure, which will, in all probability, burn the lamps out and blow the fuse.—E. AUSTIN.

Answer to No. 807 (*awarded* 5*s.*).—If the system is a three-wire one, it follows that the consumer has earthed his middle wire for the purpose of getting his light free, though I may say that if the meter is properly connected up—namely, on the outers—he could not cheat the supply company, but would have to pay for it just the same, as it would all be metered. However, such a procedure is against the regulation of the Board of Trade, to say nothing of the amount of trouble it gives to the station engineer, so we must now look for a remedy. We will suppose the installation to be one of 220 volts, with the middle wire earthed at station. First of all, insulate the middle wire, then put the positive main to earth through a variable resistance in series with an ammeter, at the same time watching the ammeter. If the consumer has at that particular time got his middle wire to earth, there will be a sudden rush of current which may throw the pointer violently over, afterwards falling to zero, indicating that his neutral fuse has blown, and as he is not allowed to break the seals of the cut-out, location is self-evident, for he will have to make application for a new fuse; such a procedure might also go to prove that the meter had been placed on the middle wire instead of the outer, as there would really be no inducement for any consumer to earth his middle wire unless he knew this. The above answer is based on the assumption that the consumer had not removed his neutral fuse.

We will now deal with a consumer who is supposed to have removed his neutral fuse. Proceeding as before, we insulate the neutral wire; the effect of earthing the outers is now different, depending on what side of the system he is connected up to. If he is connected to the positive side, and the positive pole is earthed, his lamps will no longer burn, as the main will be at earth potential, but on earthing the negative pole there will be a potential difference of about 440 volts between positive pole and earth; this would result in blowing his positive fuse, together with a general blackening and bursting of his lamps. The excessive current might also show itself on the feeder ammeter of his particular section at the moment of earthing.

Another way, if the network is not a very large one, would be to split it up into sections, testing a section each day with some portable instrument, such as Evershed and Vignoles. This would be a slow way, but a sure one, providing the culprit was not fly enough to disconnect his earth every day.—H. P.

Question No 809.—In a station having water-tube boilers working at 200lb. per square inch, and using salt water for condensing, what is the best and quickest method of detecting small quantities of salt in the feed water? The presence of the salt being due to a leaky condenser. As it is desired to avoid "blowing down" as much as possible, to what density may the water in boilers be allowed to rise to before forming a dangerous scale? What percentage of the feed water should be "blown down" daily to maintain the density at a safe value?

Answer to No. 809 (*awarded* 10*s.*).—Salt water—for presumably in the case presented by "Practical" sea or tidal water is used—varies considerably in composition,

Digitized by Google

The main constituents, however, in percentages of the total solids are of the following order: sodium chloride, 77 8; magnesium chloride, 10 9; magnesium sulphate, 4 7; calcium sulphate, 3 6; potassium sulphate, 2 5; calcium carbonate and magnesium bromide, 0 5—total, 100. Nearly 89 per cent. of the total solids being chlorides, the quickest and best method of detection is by means of the action of silver nitrate on soluble chlorides. Thus

$$AgNO_3 + NaCl = AgCl + NaNO_3.$$

A solution of silver nitrate precipitates the insoluble white silver chloride, and a ready method of determining the actual amount of chlorine—and thus salt—is presented. An indicator to determine the exact point at which the precipitation ends is needed for quantitative work, and potassium chromate is used. Thus, to detect the presence of salt, pour a small portion of the water into a clean white porcelain dish, add a few drops of a solution of potassium chromate, stir with a glass rod until the water is distinctly yellow. Then add silver nitrate solution, and if salt (or chlorine as chloride) is present a red colour is seen as the silver solution meets the water, this red disappearing on stirring, until the whole of the chloride is precipitated When this results, a permanent red takes the place of the yellow coloration. To accurately determine the amount of chlorine, a standard solution of silver nitrate is made by dissolving 4·79 grm. of pure silver nitrate in one litre (1,000 cubic centimetres) of distilled water; one cubic centimetre of this solution exactly precipitates one milligramme of chlorine. Seventy cubic centimetres of the boiler water is the best amount to take, and the silver nitrate is run in from a graduated burette until the red colour just becomes permanent on stirring. The number of cubic centimetres of silver nitrate used represents the milligrammes of chlorine in 70 cubic centimetres of the water, and, therefore, the number of grains per gallon. Multiply this by 1·68 to get the approximate grains of salt per gallon. If the water is acid, neutralise with sodium carbonate; if strongly alkaline, with nitric acid.

If sea-water in any quantity is allowed to enter a boiler working at high pressure, corrosion through the magnesium chloride is to be feared, and it is bad engineering practice to use leaky condensers served by salt water on high-pressure boilers. The best way to avoid trouble is to repair or renew the condenser, otherwise the user will always be liable to have difficulty and waste in his boilers. Marine practice allows of a density of 15deg. to 20deg. by the salinometer, which is practically a hydrometer with the density of fresh water marked zero, that of sea-water marked 10, and the scale continued to 35. A reading of 20 thus means that twice the amount of salt is in solution as would be in sea-water, and this would in no wise be allowed in land installations. Scale forming is not the primary danger, and corrosion is more to be feared, so that a minimum of salt water should be allowed.

It is the custom in a large station where the boiler feed is taken from a canal which is fed from a river just above the tidal limit, and thus contains at times a quantity of salt, to limit the maximum density to 1deg. salinometer—*i.e.*, about 130 grains of chlorine per gallon. Practically no trouble has been experienced, and this is probably due to the fact that the water is softened by a process involving the use of lime, and thus neutralising the magnesium salts. On one or two occasions when the softeners were out of use slight corrosion, as evidenced by the dirty-brown sediment in the gauge glasses, started although the density did not exceed 4deg. salinometer. It would seem that, save in very exceptional circumstances, 1deg. density—*i.e.*, 130 grains of chlorine per gallon—is a maximum, unsafe to exceed without the use of lime in the boiler itself. If this limit be exceeded, for every 100 grains of chlorine per gallon 2·6lb. of lime should be added to 1,000 gallons of boiled water. The amount of water to be blown down to keep the density which it is determined to work at depends on the density of the feed water. Assuming the density of the feed to be a degrees salinometer and the maximum allowable to be b degrees, then the quantity to be blown down is a/b of the total feed.—S. E. T.

Answer to No. 809 (*awarded 7s. 6d.*).—The best method of determining the salinity of feed water is to test it with a salinometer. A salinometer (quite an inexpensive instrument) is a special form of hydrometer, and consists of a glass or metal weighted bulb, attached to which is a graduated stem. On placing it in the liquid to be tested it floats in an upright position, and the amount to which the stem is immersed is inversely proportional to the density. The stem of the salinometer is graduated in "thirty seconds" or "ounces per gallon," sometimes in both, and reads correctly at a temperature of 200deg. F. Thirty-two parts of average sea-water contain one part by weight of solid matter; this amounts to about 5oz per gallon, so that if the salinometer be put into sea-water at 200deg. F. it will read "one" on the "thirty-two" scale and about "five" on the scale of ounces. Of this 5oz. about ·25oz. are sulphate of lime, which is the chief scale-forming constituent in sea-water. With regard to running at a safe density, Seaton gives 20oz, or four "thirty-two," as safe, but the amount of scale deposited does not depend on the density of the water in the boiler, but on the density of the feed and the amount evaporated. The salt itself is not deposited under a density of 12 "thirty-two"—a state of affairs which should not be even approached. Suppose the feed to contain ·1oz. of sulphate of lime per gallon, the water evaporated 10,000 gallons per day, at the end of three months 5,687lb. of scale will have been deposited in the boiler. If the specific gravity of the scale be 2·6, this amounts to $\frac{5,687 \times 1,728}{62·3 \times 2·6} = 60,750$ cubic inches. If the heating surface of the boiler be 2,000 square feet and the scale be deposited evenly all over it, the thickness will be ·211in.

To maintain the water in the boiler at a constant density, the water blown out must contain the same amount of solid matter as the feed has brought in since the last blow down. Hence the rule: the gallons of feed multiplied by its solid matter per gallon must equal the gallons blown off multiplied by its solid matter per gallon. Suppose it is desired to keep the boiler water density at 10oz and the feed-water density is 2oz., water evaporation per day A gallons, water blown off per day x gallons. Then

$$A \times 2 = x \times 10,$$

$$x = \frac{A}{5}.$$

Or the water blown off must equal one-fifth the total feed. This rule is not very accurate, and only serves to give one a rough idea as to how much to blow off, a process of trial and error being adopted to secure the exact result required, bearing in mind that the feed check valve must be shut when blowing down and the boiler must be pumped up again to its original level before retaking the density. If the station is situated on an estuary, there will not be nearly so much sulphate of lime per gallon as in ordinary sea-water, but this may or may not be made up for by carbonate of lime. Also the quality of the water will vary with the tides and the amount of fresh water brought down by the river. In any case, the sea-water around the British coast is not so dense as that in the open sea. Much the best way out of the difficulty, however, is to repair the leaky condenser, which, unless there are any very special reasons, should prove quite a simple matter.

Sulphate scale is extremely hard and difficult to remove, especially when carbonates are also present and the salinity of the water is favourable to electrolytic action and scum, which is apt to cause priming, so much so that marine boilers are universally provided with special scum cocks. At the same time it is usual in ocean-going steamers carrying a fresh water supplementary feed to make up the lost water with sea-water until the boilers arrive at a density of about half a "thirty-two," after which fresh water is used. This serves to put a very thin scale on the plates, which protects them against pitting and corrosion.—J. P.

[Other replies to Question No. 809 will be given in our next issue.—Ed. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

QUESTIONS.

816. Why should a Lancashire boiler give a dull boom at intervals of, say, half an hour, or less, which can be heard 30 yards away, and make the steam blow off suddenly at the safety valve when the blow-off cock happens to be leaking? The blow-off cock is of the Hopkinson type. The blow-off cock delivers below the surface of a stream of water. Also, would the above effect be likely to be at all detrimental to its safety?—ARC E. E.

ANSWERS.

Question No. 809.—In a station having water-tube boilers working at 200lb. per square inch, and using salt water for condensing, what is the best and quickest method of detecting small quantities of salt in the feed water? The presence of the salt being due to a leaky condenser. As it is desired to avoid "blowing down" as much as possible, to what density may the water in boilers be allowed to rise to before forming a dangerous scale? What percentage of the feed water should be "blown down" daily to maintain the density at a safe value?

Answer to No. 809 (*awarded* 5*s.*).—It is a very simple matter to show the presence of salt in water. It is best to get a chemical test-tube, but any glass will do. Put about an ounce of the water into it, then add two drops of pure nitric acid; stir thoroughly, and add one drop of a solution of pure nitrate of silver. If salt—*i.e.*, chloride of sodium—is present, a white precipitate or turbidity will appear immediately, and this will get darker in the daylight. Assuming that the feed water is free from mineral, etc, matter in solution, its density would be 1,000deg., and after having passed through the boilers, and so losing its gases, its density would increase somewhat in proportion to the mineral, etc., matter in solution. The mineral matter of sea-water is approximately: chloride of sodium, 2·60; chloride of potassium, ·07; chloride of magnesium, ·28; sulphate of lime, ·11; sulphate of magnesia, ·26—total mineral matter, 3·32 per 100 parts or per cent. by weight. To this must be added a very small quantity of organic matter. The density of sea-water is 1,020, and the solids found by analysis in a gallon amount to 2,700 grains, or about 6oz. Of all the above salts the sulphate of lime is the least soluble, and would therefore be the first to be deposited on the inside of the boilers.

Boiling water will dissolve about one grain in ½oz. of water as a maximum, and this is about four times as great a proportion as the sea-water contains naturally, so that the sea-water might be condensed by evaporation to about one-fourth of its bulk, which would correspond to a density of 1,080deg. after cooling to 60deg. F. This, therefore, would correspond to the maximum density allowable, as any further concentration would cause a deposit of sulphate of lime. All the other salts, being much more soluble, would not be affected. A careful consideration of these remarks will show that the amount to be blown out of the boiler bears no proportion to the amount of clean feed water pumped into the boilers, but must depend upon the amount of leakage from the condensing water, and so long as the density of the water in the boilers does not approach 1,080deg, no fear of deposit will be feared. The water must always be cooled to 60deg. F. before observing its density, and then the test must be very carefully and accurately made in a glass vessel.

The analysis of sea-water given above shows it to be loaded with other chlorides other than that of sodium, and each of these would respond to the nitrate of silver test, but, of course, that does not matter for our present purpose. However, it should be noted that chloride of magnesium is the worst enemy, because it decomposes under the influence of heat in the boilers, and so gives rise to active hydrochloric acid in the water in the boiler, and this will dissolve, and so damage the interior of the boiler and all its fittings, therefore every effort should be made to keep the condenser from leaking.—F. G. A.

Answer to No. 809 (*awarded* 5*s.*).—The best way of detecting small quantities of salt in the feed water is by using the naval hydrometer. All readers will well know the principle of and the method of using the hydrometer. The naval hydrometer, which is particularly suited for this case, differs only from other kinds in the matter of graduation. Sea-water contains $\frac{1}{37}$ part of solid matter, and the hydrometer is graduated into degrees, each degree representing the presence of one-tenth the solid matter in sea-water. Ten degrees represent the density of sea-water, or the presence of $\frac{1}{32}$ part of solid matter. The indication of $\frac{1}{320}$ part of solid matter will, I think, be enough for all practical purposes.

As regards the density to which the water in the boilers may be allowed to rise before forming a dangerous scale, this should not be more than between 30deg. or 40deg. on the hydrometer, indicating the presence of $\frac{3}{32}$ or $\frac{1}{8}$ parts of solid matter in the water. We have now to decide the quantity of feed water to be "blown down" daily to keep the density of the water at a safe constant value. Let x = the quantity of feed water and y = the water to be blown out. Then $x - y$ = the water evaporated. Suppose the water in the boiler is to be kept at a density equal to n times the density of the feed water, then the quantity of solid matter blown out is proportional to $n \times y$. The quantity of solid matter pumped in with the feed during the same time is proportional to x, and since the density of the water in the boiler remains constant, the solid matter blown out must equal that blown in. Therefore,

$$x \times 1 = y \times n,$$

or,

$$y = \frac{x}{n}.$$

Suppose that in our engine the density of the feed is 1 on the naval hydrometer—*i.e.*, $\frac{1}{10}$ the density of sea-water—and that the density in the boiler is to be limited to four times that of sea-water, in this case $n = 40$, and $\frac{1}{40}$ the total feed water must be blown out = 2½ per cent.—ERNEST P. HOLLIS.

Answer to No. 809 (*awarded* 5*s.*).—The best method of detecting quantities of salt in the feed water is by the use of the salinometer. Draw off some water from the boiler, when it has ceased the violent boiling caused by its being released from the pressure in the boiler. Try its temperature with a thermometer. If it is hotter than the degree marked on the salinometer, it must be left to cool until it comes to that degree; but if already too cool, warm it over a fire till it becomes of the proper degree. Dip the salinometer in the water so as to wet it all over, and then let it float. The quantity of salt can now be ascertained by noting the mark on the graduated scale on the stem of the salinometer the water stands at. Two hundred degrees Fahrenheit is the usual degree marked on the salinometer. The presence of salt in the feed water can be detected in another way by drawing some of the water off, boiling it and placing a thermometer in it; if the mercury rises above 212deg. it shows the presence of salt, as the boiling point of fresh water is 212deg., and that of salt water 213·2deg. It has been found by experience that when the density of water in a boiler is prevented from exceeding that point at which it contains $\frac{2}{33}$ its weight of salt, or 8oz. per gallon, no injurious scale will form. Before the percentage of the feed water to be blown down can be ascertained the density of it must be known. Assuming that the density of the feed water is $\frac{1}{132}$, or 1oz. of salt per gallon, and as the density of the water allowed in the boiler is $\frac{2}{33}$, or 8oz. of salt per gallon, it is clear that the water in the boiler must be reduced by evaporation to $\frac{1}{8}$ its bulk before it can contain $\frac{2}{33}$ of salt, or, in other words, $\frac{1}{8}$, or 12½ per cent., of the total feed water must be blown down daily to maintain the density of the water at a safe value.—GEORGE EMENS, JUN.

Question No. 810.—Discuss means of speed regulation of alternating-current low voltage motors, and state why the cost of variable-speed alternating-current motors exceeds that of constant-speed motors by a relatively high amount. What would be the best method for obtaining electrically a speed variation of 25 per cent. with a 1-h.p. alternating-current motor

Answer to No. 810 (*awarded* 7*s.* 6*d.*).—Leaving out of account a change of supply frequency as impracticable, there are only three ways of regulating an ordinary single or polyphase induction motor: (1) by changing the number of poles; (2) by reducing the stator terminal volts; (3) by inserting resistance into the rotor windings (Fig. 1) (1) only allows large changes of speed to be produced, such as those in the ratio of 1 : 2 or 1 : 4, and is, besides, expensive, owing to the special arrangement of the winding

Digitized by Google

and the large number of ends that have to be brought out to the regulating switch. (2) is only applicable for small speed changes (say 10 to 15 per cent.), for a comparatively large percentage change in terminal volts is required to produce a small change in speed. Since the maximum torque which an induction motor will develop before stopping through overload varies as the square of the terminal volts, even a good motor, standing two or three times full load with full terminal volts, very soon reaches a point where the overload capacity is too small for practical work.

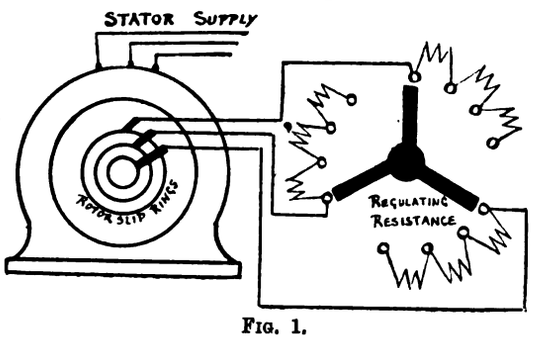

FIG. 1.

(3) is the method most commonly employed. It involves the use of a "wound" rotor fitted with slip-rings to enable the variable resistance to be inserted, and it is less efficient than either (1) or (2). It, however, enables any required speed variation to be produced, right down to zero speed if desired. The low efficiency is due to the fact that of the total energy a fraction proportional to the speed reduction effected is lost in the regulating resistance, just as in the case of an ordinary direct-current motor whose speed is regulated by inserting resistance in series with the armature. Thus, if the amounts of power taken into the motor at full speed and at 25 per cent. reduction in speed are equal, the useful power developed in the latter case will be practically 25 per cent. less than at full speed. If the machine is used at the lower speed continuously, of course this loss becomes a serious item, but if, as is more usual, the lower speed is only wanted occasionally, the all-day efficiency is not lowered appreciably. This method (3) would, therefore, undoubtedly be the best, both as regards first cost and stability of running, to adopt for the 25 per cent. reduction in the 1-h.p. motor mentioned, provided that the low speed is not wanted for a large proportion of the time. As regards the increased cost for variable-speed motors, this is only large in cases in which the normal constant-speed motor has a squirrel-cage rotor without slip-rings, for then the variable-speed motor (method 3) has to be provided with a special rotor fitted with rings (usually three) and a brush gear, often involving a fairly complete change of design. When the normal motor already has a "wound" (slip-ring) rotor the additional cost for variable speed should be little more than that of the regulating resistance, provided, of course, that the torque required at the low speed is no greater than the normal full load torque. The regulating resistance itself, especially in the case of small machines, is a somewhat expensive item, for, besides the fact that it has to dissipate a very large amount of energy (compared, for instance, with that of the shunt regulator of a direct-current motor), it has to have three arms and sets of contacts to correspond with the usual three slip-rings on the rotor.—Q.

Answer to No. 810 (*awarded 7s. 6d.*).—In induction or so-called constant-speed motors, the speed can be varied both by stator and rotor devices.

1. *Stator Regulation.*—(*a*) *Alteration in Number of Poles.*—This is a very good method when the speed is to be halved. The stator coils are in two sets, one of which can be reversed. The poles, which would be with eight poles, + −, + −, + −, + −, would become + −, − +, + −, − +. Two adjacent similar poles would act like a consequent pole. The great advantage of this kind of regulation lies in the fact that no energy is lost by the change. It corresponds but is not equivalent to the regulation of direct-current motors by alteration of the field current.

(*b*) *Alteration in the Frequency of the Working Current.* This method would be too expensive, as another machine would be required, and it would be cheaper to have two separate motors for the two different speeds.

2. *Rotor Regulation.*—(*a*) *Introduction of Resistance into the Circuit of the Rotor.*—The effect of this is seen most plainly with the aid of the given Heyland diagram. The details of this cannot be explained, as they would require too much space. $B_1 C_1$ represents the output that would be got when the rotor slip was 5 per cent. If $B_1 C_1$ represents 1 b.h.p., then with this motor a slip of 15 per cent. would be obtained when the rotor was giving out energy to the amount represented by $B_3 C_3$—*i.e.*, about 2·2 b.h.p.—and, therefore, 1·2 b.h.p. must be dissipated as heat in the rotor rheostat. Even though approximately only 10 per cent. variation in speed has been obtained, the motor has nearly reached its maximum output. More work, of course, can be got out of the motor, but not any more available reduction of speed. The amount of energy represented by $X C_3$ can be made use of by putting on a load equal to $B_3 C_3$ and cutting out the rotor resistance, but the speed will be exactly the same. $A_2 D_2$ represents its output as a constant-speed motor. Diagram I. would not be suitable for a 1-b.h.p. induction motor, but such a motor would very likely be worse in its regulation. On testing a ¼-b.h.p. three-phase induction motor, the variation of speed from no load to 100 per cent. overload was found to be only 18 per cent of the no-load speed.

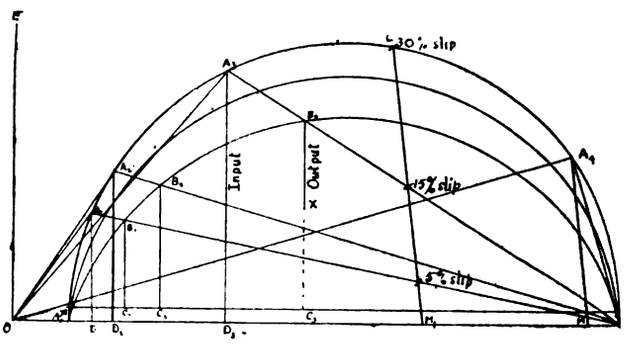

DIAGRAM I.

(*b*) *Cascade Regulation or Tandem Control.*—This is a variation of (*a*), where the energy represented by $X C_3$ in the first diagram is passed on to the stator of a coupled motor. This motor adds to the torque and prevents dissipation of energy as heat. The second motor has a starting resistance in its rotor circuit. The speed of the two when coupled is half that of either running alone. Supposing we consider the stator-rotor transformation ratio to be unity in both cases, we may approximately take the currents in the rotors of both to be equal. The torque of each motor will be the same as if it were running alone with this current, and, therefore, the number of revolutions for any particular output must be halved when the two are coupled.

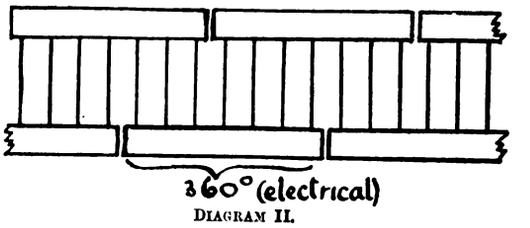

DIAGRAM II.

The best kind of motor to use for 25 per cent. speed variation would be a compensated series alternating motor where the armature is fed by a transformer from the stator circuit. The voltage on the armature could be varied by any reasonable amount, and the armature would have to speed up to produce the necessary back E.M.F. Such motors are not yet on the market in small sizes. The reason for the extra cost of variable-speed induction motors is that the rotor has to be wound and connections made to slip-rings, and these connected to a three-way rheostat, whereas a so-called constant-speed motor has a rotor circuit composed of straight conductors with the ends short-circuited, as shown in Diagram II. (Osnos type).—E. S.

Answer to No. 810 (*awarded 5s.*).—There are three commercial methods of electrically varying the speed of induc-

Digitized by Google

tion motors: (1) by changing the number of poles; (2) variation of supply voltage; (3) resistance in rotor circuit.

1. The method of pole changing has been discussed at length in these columns quite recently; it has the following disadvantages: (*a*) The ratio of speed variation is practically fixed—a ratio of 2 to 1 is that chiefly employed. Other ratios of 4 to 3, 4 to 1, etc., can also be arranged, but with considerable complication. For a ratio of 2 to 1 the motor would be wound with the larger number of poles—*i.e.*, for the lower speed—with this arrangement the whole of the windings are active at both speeds, but with the other ratios mentioned above it is generally necessary to wind the motor with two or more separate windings—depending on the speed ratios required. With this system it is difficult and costly to arrange for small speed variation. (*b*) The switchgear is complicated with low-speed motors where separate windings are not used. (*c*) With reduced speeds the leakage increases, due to the larger number of poles, and the power factor decreases. The advantage of the system—especially with the 2 : 1 ratio with common winding—is that the efficiency is fairly high at both speeds, the decreased efficiency at the lower speeds being due to the increased rotor losses. The system is satisfactory where the motor has to run at either speed for any length of time.

2. The speed variation by means of supply voltage is chiefly used with "squirrel-cage" rotors, and is fairly satisfactory where the required speed variation does not exceed 50 per cent. The general practice is to wind the rotor with somewhat high-resistance coils, so that small changes of voltage produce a wide range of speed; the rotor C^2R losses, however, are permanently increased. It must also be remembered that the torque of induction motors varies as the square of the impressed volts.

3. The speed variation by rotor resistance is that chiefly employed, and generally meets with the average requirements where wound rotors are used. A liquid or metallic resistance is connected in the rotor circuit, the slip or speed variation being directly proportional to the resistance. The speed, therefore, can be varied within very wide and fine limits, as desired. The disadvantage of this method is the large C^2R losses in the resistance, the efficiency varying approximately as the speed with constant torque. The power consumption is, therefore, the same at all speeds, as in the case of the continuous-current motor with speed regulation by armature resistance.

Regarding the extra cost of variable-speed motors over the constant-speed motors, with method (1) the extra cost is due to the switchgear for changing the pole connections with motors with common windings, but with separate windings the motor size is increased, due to larger or more numerous slots. The rotor construction with wound rotors is also increased—*i.e.*, slip rings and brush gear—as it is necessary to wind for both speeds. No complicated switchgear is necessary for the motors with separate windings, a simple change-over switch only being required. (2) The extra cost of this method is only due to the auto-transformer to vary the voltage. The motor size is not increased. (3) With this system the motor size is not increased, the extra cost being only due to the regulating resistance, which depends on the speed variation required.

The best method of obtaining a speed regulation of 25 per cent. would be by rotor resistance with a wound rotor, or varying the voltage with a "squirrel-cage" rotor. It has been assumed that the motor in question is of the two or three phase type, although the writer has obtained satisfactory results with ordinary single-phase induction motors fitted with wound rotors and a speed regulation up to 25 per cent. with rotor resistance.—JUNO.

Answer to No. 810 (*awarded* 5*s*).—The factors upon which the speed of an induction motor depends are given by the equation

$$\text{R.P.M.} = \frac{\text{frequency}}{\text{number of pairs of poles}} \times 60.$$

This speed, however, is not that of the rotor, but that of the rotating field caused by the stator windings. The actual speed of the rotor differs by a small amount, known as the slip, from that of the rotating field. In most cases the rotor speed will be not more than 3 per cent. lower than that of the field. Now this slip is directly proportional to the resistance of the rotor winding.

From these facts it is clear that there are three direct methods of altering the speed of the rotor: (1) Alteration of the frequency of the supply. This method is obviously only available for very special cases, and need not be considered. (2) Variation of the number of pairs of poles of the stator windings. This arrangement is very inflexible, as unless a large number of poles are provided the steps are very great; thus a two-pole machine converted to four-pole will have its speed halved, and the larger the number of poles the greater become the difficulties of winding and switching over. (3) By altering the resistance of the rotor winding. This method, combining as it may the office of starter and controller, is easy and flexible; the windings, usually connected in star, are led to slip-rings, and a resistance may be included in the circuit, with speeds corresponding to each stop and a final position short-circuiting the resistance for the maximum speed. The main disadvantage consists in the fact that the torque and stator current will remain practically the same for all speeds. Thus at the lower speeds there is great waste of energy, as the output of the machine will decrease with the speed, while the power used will remain constant. In fact, the arrangement may be compared to the speed regulation of a shunt motor by inserting resistance in series with the armature.

Apart from these methods of altering speed, applicable to single motors, there is a method equivalent to the series-parallel control of direct-current motors. This is known as the tandem or cascade control, in which, instead of putting a resistance in the rotor circuit of No. 1 machine, the stator of a second machine is switched in, this second machine being designed to run at a lower speed and lower frequency; the two machines are coupled together, and machinery may be run from No. 1 machine alone at full speed, or with both machines at a lower speed, but with increased torque due to the second machine.

As regards the question of the price of variable-speed motors, there are obvious reasons for their relative costliness: (1) there is not such a great demand for them, consequently they are not made in large quantities, which naturally results in higher prices being demanded; (2) if made with a variable number of poles, a number of subdivisions of the winding are needed, increasing the labour, and a costly and complicated switchgear is required; (3) if made with variable resistance for rotor slip-rings are required and squirrel-cage windings cannot be used—moreover, the machine must be made of such a size as to develop its full output at its lowest speed, thus being larger than if built to give its output at the higher speed. The increased cost of the tandem system is so obvious as to need no comment.

The best method to employ for obtaining 25 per cent. speed variation for a 1-h.p. alternating-current motor is probably that of inserting a resistance in the rotor circuit, as this will only entail a drop in efficiency at the lower speeds, and will permit the use of intermediate speeds, while the winding the stator with eight poles, convertible to six, would be impracticable in the case of so small a motor.—H. W. B.

Answer to No. 810 (*awarded* 5*s*.).—There are three chief methods of varying the speed of induction motors: (1) by changing the number of poles in the stator; (2) by inserting resistances in circuit with the rotor; (3) by varying the voltage applied to the terminals of the motor by means of a compensator.

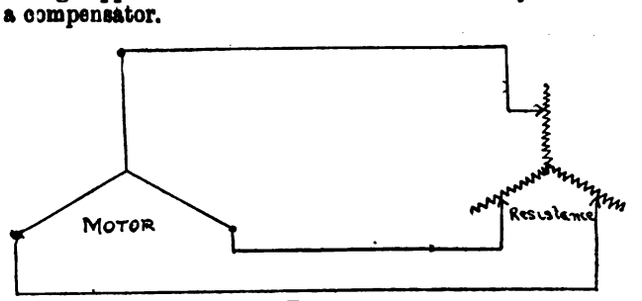

FIG. 1.

The first method has been well discussed in these columns very recently in answer to Question 794, so that I do not think that any explanation is called for here. The second

Digitized by Google

one has not been explained recently, so that I will briefly consider. As is well known, the slip of an induction motor varies inversely as the rotor flux. Now, of course the rotor flux is proportional to the rotor current, so that it follows that if we diminish the rotor current by inserting resistance in the rotor, we can increase the slip of the rotor, and, therefore, diminish the speed. The connections of the resistance are as given in Fig 1. Thus by altering the value of the resistance, which is easily adjustable, we obtain various speeds for the motor.

The diagram of connections for the compensator used in the third method—*i e*, by varying the voltage across the terminals of the motor—is given in Fig. 2 L_1, L_2, L_3, M_1, M_2, M_3 are knife-blade terminals, and are mounted on a wood block, to which is connected the switch handle. T_1, T_2, T_3, T_4, T_5 and T_6 are connected to the small transformers. With the switch handle thrown over towards the transformers it will be seen that we have only a fraction of the voltage across the terminals, and when over towards F_1, F_2, F_3, F_4, F_5, and F_6 the full voltage of the mains is across the terminals of the motor. Having briefly described the three different methods, I have next to discuss their merits.

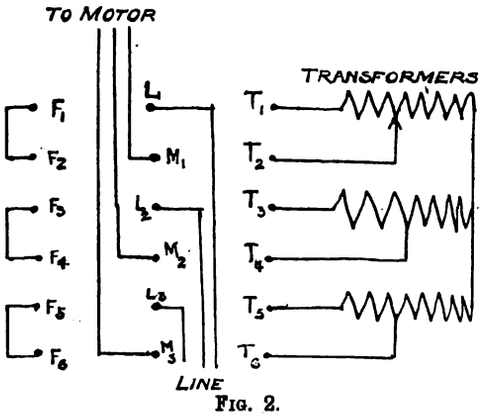

FIG. 2.

Each of the above has its own field of operation. The third method is the one mostly used in starting up machines in works. The simplicity of the compensator makes it especially useful for this. The second method can be and often is used for starting up machines in power stations where the method of operation is well understood. The first method can be used when a variable speed is required, but it will only give a few different speeds. Suppose we had a motor running at 400 r.p.m. with a frequency of 40 cycles per second, then the number of pairs of poles are $\frac{40 \times 60}{400}$ = six pairs of poles. With this number of poles we could get 45 different speeds by reducing the number of pairs of poles down to 4, 3, 2, and 1. With a proper resistance we could obtain several more intermediate speeds. With regard to the speed regulation of the 1-h.p. motor in the question, I think that, as the motor is only a small one, the second method would be best, because as the speed variation is only 25 per cent., the capital cost of the whole affair—motor and resistance—would be less than the pole-changing method. However, there is not much in it. The reason that the variable-speed motors cost most is because of the high cost of the pole-changing gear and of the resistances.—ERNEST. P. HOLLIS

Question No. 811.—It is desired to instal a motor generator of 50 kw. capacity for interconnecting an alternating-current 2 000-volt 75~ system with a direct-current 460-volt system. The alternators are of the ironless core type, and the dynamos are compound wound. Describe the controlling arrangements for the set to be started up as a motor from the direct-current side, but to run either as an alternating-current or direct-current generator in parallel with the existing plant. Give a diagram of the necessary connections.

Answer to No. 811 (*awarded* 7*s.* 6*d.*).—Since the main direct-current dynamos are compound wound, it will be necessary for the direct-current machine of the motor-generator set also to have a compound winding, but it will be best to use the series turns only when the direct-current side is a generator, as at other times this winding would merely act as a shunt to the series windings of the main generators and spoil their self-regulating properties. In order to be able to dispense with the series winding in this way (when the direct-current side is the motor), it will, of course, be necessary for the direct-current machine of the motor-generator set to have sufficient shunt excitation to let it run at the normal speed at all loads as a shunt motor. In most machines this would be the case, but if it is found that the shunt is insufficient, the series winding can be left in at all times without any change in connection, though it may be necessary to regulate the main generators partly by hand in consequence. The diagram of connections, assuming that the series winding is to be cut out, would be as in Fig. 1, and the process of operation would be as follows. To start up (for use as a generator on either the direct-current or alternating-current side) move switch A to the dotted position, so as to cut the series winding out and connect the dynamo brush direct to the outer bus bar. Then close the starting switch, B, slowly starting the set up. The alternator field is next excited by means of switch D, and the alternator volts are adjusted to the right value (2,000) on voltmeter V_1. The

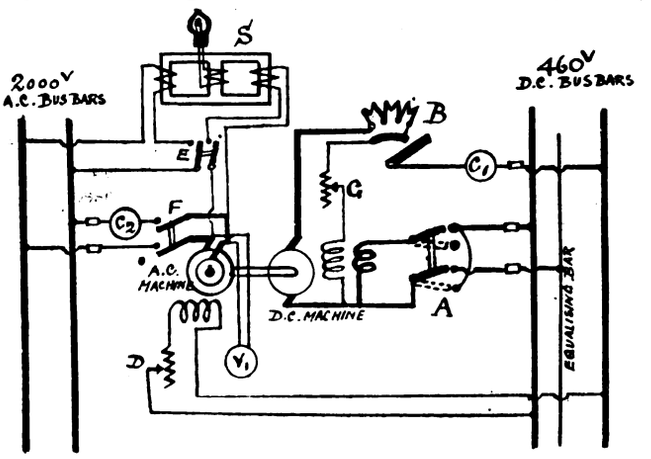

FIG 1.

synchronising switch, E is also closed, and when synchronism is indicated on the synchroniser, S, the speed being adjusted by switch G, the main alternator switch, F, is closed. The set is then in a position to act either as a direct-current generator driven by a synchronous alternating-current motor, or as an alternator driven by a shunt direct-current motor.

1. If the direct-current side is to be the generator, the next step will be to strengthen the direct-current field by switch G until the ammeter C_2 indicates no current (or even a slight generated current). Then move switch A into the full-line position, and strengthen or weaken the shunt by G in order to get any desired load out of the direct-current side, just as in the case of an ordinary steam-driven direct-current compound dynamo. At the same time the field of the alternator will require a slight adjustment, by means of switch D, in order to ensure its taking the minimum possible current, as indicated on C_1, for the particular load in use. This adjustment, however, would be very slight in the case of a coreless disc alternator, and if the field is once set at the best value for half load it can probably be left unaltered from no load to full load without much loss.

2 If the alternating-current side is to act as the generator, leave switch A in the dotted position permanently and weaken the direct-current shunt by means of G until the desired load is given out by the alternating-current side, at the same time suitably strengthening the alternator field by switch D. If the series winding of the direct-current side is not to be cut out when the machine is acting as a motor, the only alteration required will be in switch A, which will be an ordinary double-pole switch without special contacts, and it will make the full-line connections permanently. It will be seen that, owing to the presence of the equalising bar, no reversal of current through the series winding will take place when the direct current machine is converted from a dynamo into a motor.—Q.

[Other replies to Question No. 811 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

QUESTIONS.

817. A car weighing 10 tons when loaded gets out of control down an incline of 1·5 in 100, and moves at the rate of 20 miles an hour, and on the application of the emergency brake it is pulled up in a distance of 20 yards. What is the energy dissipated, the average brake power, the retardation, and the time taken in pulling up?—A. D.

818. I am anxious to study the wave forms in various parts of an alternating-current circuit. Can anyone describe the construction of a simple form of "oscillograph"?—FIFTYQUIDA.

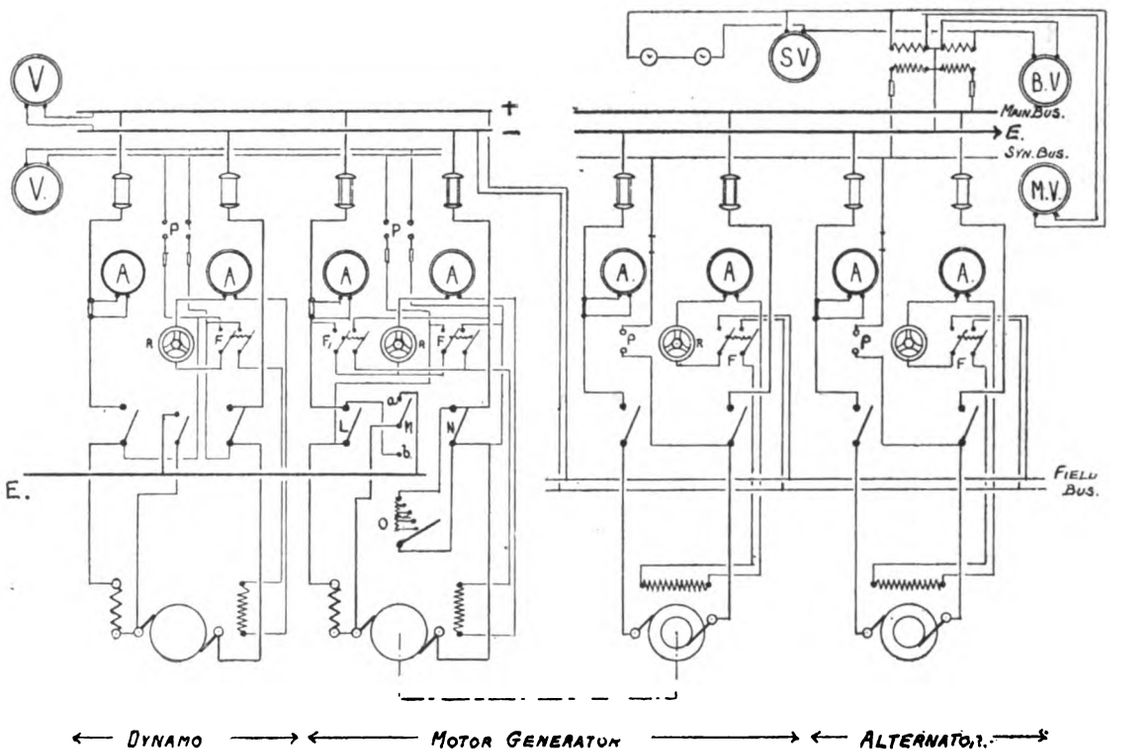
ANSWERS.

Question No. 811.—It is desired to instal a motor-generator of 50 kw. capacity for interconnecting an alternating-current 2,000-volt 76 ~ system with a direct-current 460-volt system. The alternators are of the ironless core type, and the dynamos are compound wound. Describe the controlling arrangements for the set to be started up as a motor from the direct-current side, but to run either as an alternating-current or direct-current generator in parallel with the existing plant. Give a diagram of the necessary connections.

Answer to No. 811 (*awarded 7s 6d.*).—In providing the controlling gear for such a small unit as a 50-kw. motor-generator, one needs to consider the question from, among others, the standpoints of (1) reliability; (2) cost; (3) utility. The relative importance of the second item will depend upon the size of the station, but in any case it should bear a due proportion to the cost of the set itself. Again, while it would probably be desirable to make it conform to the rest of the switchgear, yet none but necessary apparatus should be included, on the score of cost. Let us assume a small station with single-phase alternating-current plant, and with the general arrangement of the switchgear shown on the "dynamo" and "alternator" panels in the figure. Since the motor-generator is to be run in parallel with compound-wound dynamos, we will assume the generator to be compound wound, to include this case — though this is by no means necessary, and increases cost. On the panels marked "motor-generator" I have shown the essential connections for running such a machine coupled to its single-phase synchronous motor. It will be noticed that two field switches are provided for the generator. One is arranged to give the excitation from the 460-volt direct-current 'bus bars and the other couples the field on to the generator terminals. The use of these switches becomes apparent later.

O is a resistance switch divided into sections of such value as to limit the starting current to a reasonable amount, and whose exact resistance depends on the armature resistance of the generator and the supply pressure. Except for these and the double-throw equaliser switch, the gear is similar to the dynamo arrangements. P is merely a paralleling voltmeter plug. Only one of these is in use for either board, the alternating-current and direct-current plugs being sufficiently dissimilar to avoid their insertion into the wrong sockets.

The operation of starting is as follows: The 'bus-bar field switch of the generator is closed and the field brought up to a maximum. Switch O being open, M—the equaliser switch—is closed to *b*, this being connected to the + 'bus bar through a fuse. Next, O is closed step by step as the machine speeds up, when N is closed and O again opened full. The set is now to be synchronised with the alternating-current 'bus-bar pressure. Close the left-hand alternator (motor) switch and insert the paralleling plug. Now, with the field resistance all in, close the field switch and bring the motor excitation up to normal. The lamps and synchronising voltmeter will now be indicating; synchronise by reducing the generator field and parallel. The generator field switches must now be changed over



(this can be done without breaking the field so long as M and N are closed). Now open out M and N and close L and M on to *a*. Bring machine volts up to 'bus volts and close N, putting the motor-generator in on the load. To pick up load on the direct-current side increase generator field, and to pick up load on alternate-current side decrease generator field, which will then be acting as motor. No regulation can be effected with the single-phase motor field. This should be adjusted to give minimum current when motoring, and to maintain voltage when generating. A speed indicator should be provided on the motor-generator, for use when running the alternate-current load alone.

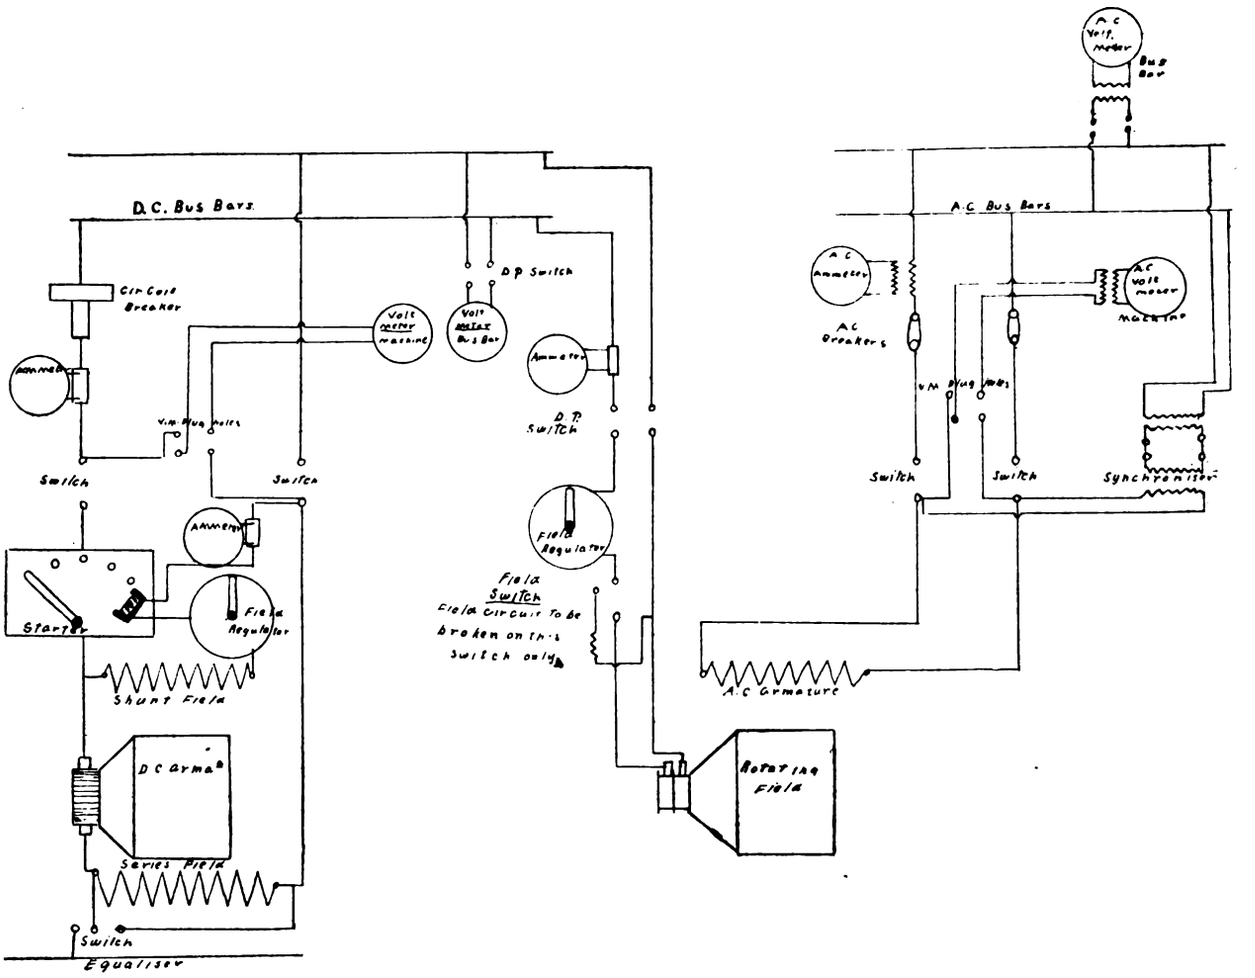
The necessity for self-exciting the generator becomes apparent when we remember that in the event of the fuses blowing it would be impossible otherwise to open the switches to replace a fuse without breaking the field. It should be noted that the two field switches should never be in together except when either M and N (M being in *b*) or L and N are both in, otherwise the armature becomes connected to the 'bus bars through the field switches. The field discharge resistances are shown separate, but need not be so. The field switches should clear the discharge contacts when "off," and a pause should be made on these

Digitized by Google

contacts when opening to give time for the field to collapse slowly.

Note.—By an error a fuse has been shown on the earthed pole of the alternators; this should be omitted as unnecessary.—PERPLEX.

Answer to No. 811 (*awarded* 7*s.* 6*d.*).—In this question the number of phases is not stated, and so the writer has assumed a single-phase plant. The diagram shows the connections for an installation which seems to meet the case. The following notes on working will serve to explain the diagram more fully than the references. On the direct-current side is shown a compound-wound machine designed to run as a shunt motor or compound generator. A throw-over switch is shown for operating the series field, which will allow of connection being made to the equaliser bar, or the series-field short-circuiting cable. This is necessary to enable the machine to run at an even speed as a motor, which is essential in the present case, for the compound winding will probably be designed for over-compounding when generating, and if left in circuit when motoring it would necessarily weaken the field as the load increased, and cause unsteady running. On the alternating-current side an ordinary synchronous motor is represented, with a rotating field excited off the direct-current bars, with a field regulator in circuit. Synchronising gear is also shown.

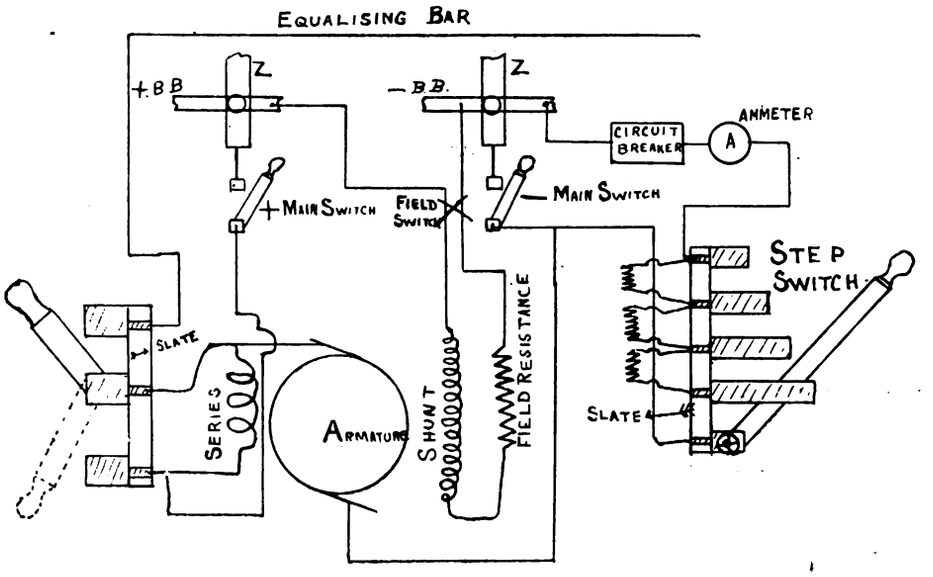


In starting up, the following is the method that should be employed. Short-circuit the series field, and close the circuit breaker and main switches on the direct-current side, then close the armature circuit through the starter. The exciting circuit on the synchronous machine must next be closed. Before closing the alternating-current switches, it is necessary to bring the machine up to synchronous speed, and also up to voltage. The former operation is performed on the direct-current machine by means of the field regulator shown in the left of the diagram, which adjusts the resistance in the field circuit, thus regulating the speed. Adjusting the alternating-current voltage is performed on the exciter field regulator, shown in the centre of the diagram. When the voltage and speed are correct, the alternating-current main switches may be closed. To run the set as an alternating-current generator, the load regulation must be made on the exciter field regulator, increasing the exciting current, causing the machine to take up its work. To run the set as a direct-current generator, switch in as directed above, and regulate the load on the direct-current machine field regulator, increasing the field current, causing the voltage to rise, and the machine to take the load. When a small load has been put on the direct-current machine (working as a generator) close the series field switch on the equaliser bar, when the machine will be working as a compound generator. If the machine is working on a traction or other variable load in parallel with compound generators, some difficulty may be experienced in paralleling on the alternating-current side, due to voltage variation on the direct-current bars. In place of the ordinary synchronising lamp a synchroscope would be advisable, as ready indication is given of the speed of the incoming machine, whether too fast or too slow.—E. P. A.

Answer to No. 811 (*awarded* 5*s.*).—The following is a description of plant that has been working satisfactorily for the last three or four years. The step switch shown in the diagram is out of proportion to the main switches, but this is to emphasise it as the querist desires. It is advisable to start up the machine as a shunt motor; this will necessitate a short-circuiting switch for the series coils. If starting up compound, there should be an equalising bar fixed so that any two machines required to be run in parallel can be connected on to it. The top contacts of the mains switches are connected to copper strips, Z, which run vertically up the board, and can be plugged on to any 'bus bar. The shunt coils and the synchronous motor field leads are also connected to these strips. Before starting up see that the field resistance is all out, making the field as strong as possible. For starting, a step switch is used, the resistances between the contacts being able to carry about one-third of the full current for a minute or two. (The first coil of the resistance is slightly thicker than the others.) The length of time the switch is kept on each step is determined by watching the ammeter in circuit. As the machine gathers speed and the back E.M.F. rises, the current will drop to a very small amount. When the step switch is in the top contact, raise the speed of the

Digitized by Google

machine by weakening the fields, and make the fields of the alternate-current machine synchronise in, trip the circuit breaker (which is in circuit as a safeguard though not essential), and take out the step switch. The set is now running from the alternate-current side, and is to be paralleled in with the 46 ampere-volt system. This can be done with a paralleling voltmeter, which is placed in two contacts let into the switchboard. The contacts are connected through a fuse to the top and botton of the – switch, and when the voltmeter reads zero, showing that there is no difference of potential between the top and bottom of the switch, close the switch. The machines can now be used to generate either alternating or continuous.—F. B. M.



Answer to No. 811 (*awarded* 5*s.*).—Having a long acquaintance on a large power company with a considerable number of motor-generators, I can recommend the following method of starting up as one which will well suit the case. The great point is to start the machine up with a small amount of current, in order that there may be no kicks on the voltage of the lighting system. As the motor-generator in question is only a very small one, indeed, there is not much danger of any large kicks in voltage when starting up, as, in the first place, it will take little current to start, and, secondly, when started it will quickly come up to speed, and if there has been any drop or rise in voltage it will quickly recover itself. The best way of doing this is by inserting a resistance in between the lighting system and the motor-generator terminals. The best kind of resistance switch to use is the step resistance. I have found that the general idea of this starting resistance is not understood by those who are not acquainted with motor-generator sub-station work. In Fig. 1 I have given a cross-sectional elevation of the switch, and also a diagram of connections of the resistance. It will be seen that, on putting the starting switch on the first contact, all the resistance will be in circuit, and the machine will start up slowly, and when it has developed sufficient back E.M.F. the current taken will die down to a small amount, and the switch can then be advanced to the second contact, and so on. When, finally, the last contact is reached all the resistance is cut out, and the full voltage of the lighting system will be across the terminals of the motor-generator. Herewith I have given a diagram of connections showing fully the complete arrangement. The auxiliary starting circuit consists of (1) an auxiliary switch, (2) a circuit breaker or fuse, (3) the step starting switch described above, (4) an ammeter. There is an extra contact put on the equaliser switch of the machine (if it be not already there), so that when the switch is in one position it acts as an equaliser switch, but when in the second position it short-circuits the series turns on the direct-current side; the reason for this I will describe later.

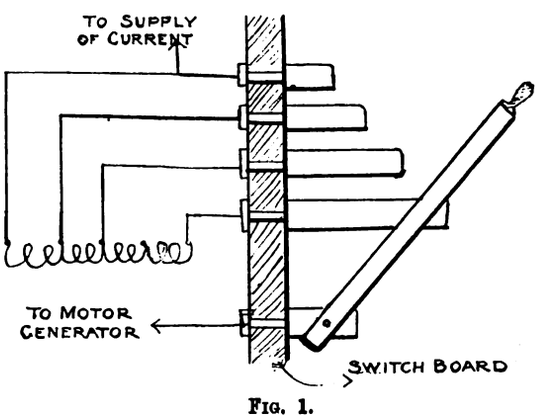


FIG. 1.

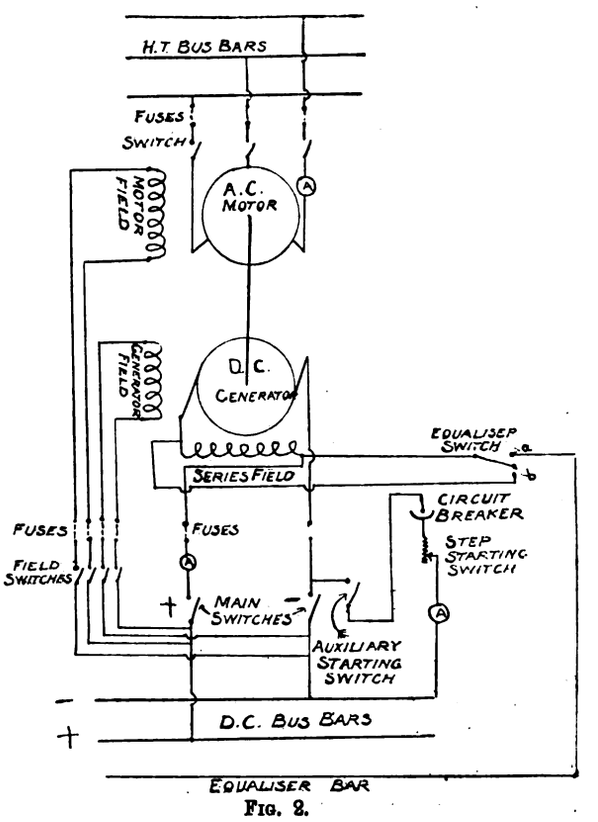

FIG. 2.

I will now go through the complete process of starting up the motor-generator, which can be followed on the diagram. First cut out all the resistance of the field of the generator, put in the field switch. We must have as strong a field as possible in order to start up slowly. Now, always on starting up *the series turns must be short-circuited*, or the starting current will weaken the field and the machine may run away, so put the equaliser switch in its proper position for doing this. Now put in in order the following: positive main switch,

Digitized by Google

auxiliary switch circuit breaker. We are now ready to start up the machine. I may here say that a fuse may take the place of the circuit breaker, but the latter is the more useful, as the only time it is likely to come out is, perhaps, in a shut down, when we are in a hurry to start up and have been too quick with the starting switch, and it will take a considerable time to replace the fuse. Now put the step starting switch on its first contact, and the machine will start up. Note on the ammeter when the starting current has died down and bring the switch up on to the second contact; repeat this till all the resistance is cut out. Then weaken the field by means of the field rheostat (not shown in diagram) until it is near synchronous speed. If the motor is just an induction motor, then the high-tension switch may now be put in. If it is a synchronous motor, put in motor field switch, raise volts to the voltage of 'bus bar, and synchronise in the usual way. Then trip the circuit breaker in the starting circuit, and take out step and auxiliary switches, parallel in with the negative main switch in the usual way, first of all compounding the machine by putting the equaliser switch in its proper position. Thus the operation of starting up has been performed.

There is one observation I must make, and that is when the motor-generator is to be used for converting direct into alternating current, the series turns on the direct-current field *must be short-circuited*. The reason for this is obvious. We shall weaken the field by passing the current round the series turns, as they are then in opposition to the shunt turns on the machine.—ERNEST P. HOLLIS.

Question No. 812.—The owners of an isolated low-tension direct-current lighting and power installation in the colonies, supplying current to about 50 110-volt motors, varying in power from 1 h.p. to 55 h.p., are anxious to establish a repair shop on the premises, equipped with the necessary plant to effectually carry out all winding and repairs due to breakdowns and ordinary wear and tear. The motors are all of the four-pole type by various British manufacturers. Describe the most modern appliances for this class of work, with special reference to the possibility of manufacturing commutators at a reasonable outlay.

Answer to No. 812 (*awarded 7s. 6d.*).—In this question I assume that "G. F." does not wish to go to any unnecessary expense with his workshop, therefore the following tools will be absolutely necessary. First of all you will require a lathe—this should have back gears, screw-cutting, and traversing arrangement. The diameter of the largest armature would be helpful in this question, but I will suppose that the lathe centres are 7in. from the bed; this means that if anything more than 14in. diameter is to be machined on the lathe, it will require the headstock, poppit, and tool rest to be packed up (which is very common in practice) with wood, or, better still, to have castings made and machined to fit the bed. This would come cheaper than having a larger lathe, also being more convenient for the smaller work. Now, when a lathe is packed up as described above, it generally puts the traversing arrangement out of action, owing to the wheels not meeting. This may be overcome by running a small flat belt off the driving wheel on to the driven, the only difference being that the direction of traverse will be reversed. The next thing you will require is a drilling machine with small drill chuck and set of drills. The machine I would recommend is one by Barnes and Co., which stands about 5ft. 8in. in height, having a traversing arrangement and taking any size drill from $\frac{1}{16}$in. to about 1$\frac{1}{2}$in., and capable of drilling anything up to 3ft. in height. You will also find a hand drilling machine very useful for doing small jobs without taking a machine to pieces. Next, you will need several sets of taps, ranging according to size of screws on machines; also screw dies. The latter need not go above $\frac{1}{2}$in. diameter, and any larger screws can be made on the lathe providing you get a set of chasers for finishing these larger sizes after screw-cutting. A small stock of standard bolts and nuts will be found very useful, and also a small quantity of hexagon steel of various sizes for odd sizes of bolts and nuts. A small shaping machine would certainly add to the convenience of the workshop, but is not absolutely necessary, as such jobs as slotting and putting keyways in shafts, etc., can be done on the lathe. The lathe may also be used as a winding machine for field-magnet coils in the following manner. Arrange the coil former in the lathe so that it runs fairly true, fix a small groove pulley in the tool rest to guide the wire on to the former, then traverse the guide pulley along by means of the screw-cutting wheels, which are easily calculated. For example, suppose the wire to be wound is 1mm. diameter, then wheels capable of cutting 26 or 27 threads per inch would do, thus allowing a little for insulation. The direction of traverse would have to be reversed for the backward journey, but this is generally a very simple matter. You will also have to be prepared for the burning out of armature coils, and I think the following would be advisable: get three or four finished coils for each size of armature from the makers of the motors; then, if any breakdown in this respect occurs, it is only a simple matter to remove the burnt coil and insert a new one. Probably the worst job will be winding the wire bands on the armature again, but this is not a long job if done on the lathe. The following sundry tools will be found necessary: hacksaw, tap wrenches, various sizes and shapes of files, three-jaw self-centering chuck and carriers for lathe, a small portable forge for forging tools for lathe, etc., an emery wheel about 6in. diameter and $\frac{3}{8}$in. wide, leaving unmentioned such tools as hammers, chisels, etc., which are absolutely necessary.

Now as regards commutator making. The writer does not think it advisable to attempt making them all through, but rather to buy the bars ready shaped (as shown in Fig. 1), and build them up yourself. The uniformity in thickness of the mica insulation is a very important item.

FIG. 1.

This should be ganged for thickness and cut to size before commencing to build. You may then start in the following manner: Turn up a piece of hard wood to the same diameter as the inside of commutator to be built, erect it vertically on a flat surface; then start to build the segments up around it, taking care that all the mica used is sound, otherwise it will undoubtedly cause endless trouble. When the desired number of bars are all built round, get two steel bands (as shown in Fig. 2), place them round the commutator, and tighten up slightly.

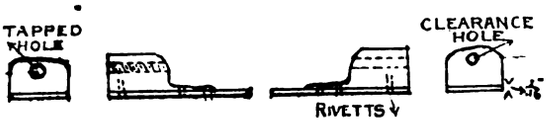

FIG. 2.

The wooden centre can now be removed, after which the bands must be tightened up as much as possible. The commutator is now ready to have its ends turned up to fit the end plates. When this is done the ends can be bolted on in the ordinary manner, the bands removed, and the commutator put on a mandrel and turned up over the top. Now comes the end connections. These may be of several forms: (1) If the armature is wound with round wire, the ends of the segments can be drilled, the ends of the wire inserted and soldered in. (2) If wound with rectangular bars a spider will have to be fitted to the commutator, and may be done in the following manner: Drill a small hole in each commutator segment the required distance from the end and not more than $\frac{1}{4}$in. deep. Again put the commutator on a mandrel in a lathe, and with a thin parting-off tool fixed horizontally in the tool-holder proceed in the same way as you would in slotting a shaft on the lathe—viz., by winding the tool forward and backward, putting on a small cut each time before the forward stroke. I have suggested the method of slotting to do away with the expense of a milling machine. The last thing is to solder on the copper connections, this being a very simple matter. You will find a good illustration of a spider in Maycock's "Electric Lighting and Power Distribution," p 375, vol. i.—E. W.

[Other replies to Question No. 812 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

819. A three-phase plant generates current at 440 volts for power and transformed to 120 volts for lighting. The lighting circuit was originally wired for 240 volts continuous current. Could the transformers be dispensed with, and current taken from the mains and neutral point earthed, to obtain more light at about 250 volts? And taking, say, 100 amperes on each phase, what would be the current in the neutral wire?—STEAM-TRAP.

820. Two single-phase induction motors of exactly same horse-power but by different makers, when doing similar work require exactly same current and same voltage. Wattmeter, however, on motor No. 1 registers only two-thirds that of meter on No. 2. (1) Is this because power factor of first motor is only two-thirds that of power factor of No. 2? (2) As current × voltage is much greater than watts paid for, who pays for lost energy? (3) Does not the above point to the suggestion that if two motors of similar amperage give same torque, but that one has lower power factor than the other, the lower power factor one is cheaper to run from consumer's standpoint?—AMATEUR.

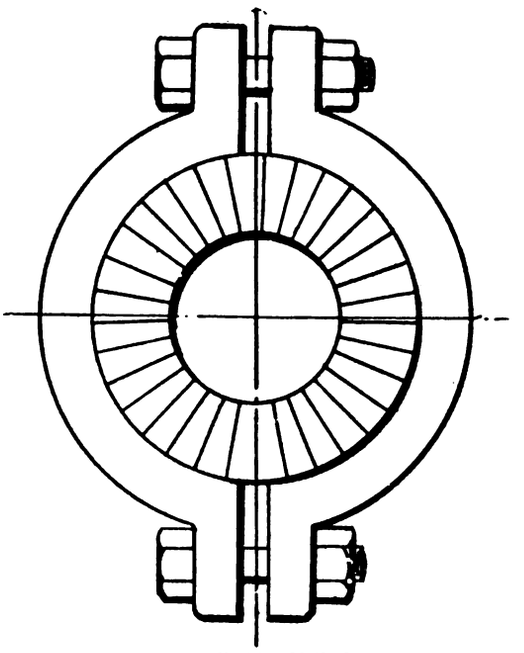
ANSWERS.

Question No. 812.—The owners of an isolated low-tension direct-current lighting and power installation in the colonies, supplying current to about 50 110-volt motors, varying in power from 1 h.p. to 55 h.p., are anxious to establish a repair shop on the premises, equipped with the necessary plant to effectually carry out all winding and repairs due to breakdowns and ordinary wear and tear. The motors are all of the four-pole type by various British manufacturers. Describe the most modern appliances for this class of work, with special reference to the possibility of manufacturing commutators at a reasonable outlay.

Answer to No. 812 (*awarded 7s. 6d*).—In a repair shop of this description, generally the work has to be executed with the utmost speed, but it does not call for any high-class automatic tools, such as capstan lathes, etc., and, further, need only be a small shop. As British-made motors are used throughout, there will not be much cause for repairs due to faulty material or workmanship. The necessary equipment would be approximately as follows.

Machine Shop.—Back-geared, screw-cutting lathe large enough to accommodate largest armature, fitted with surfacing and traversing motion. Provided with a large gap, this machine may be used for all sorts of boring and turning, and fitted with a revolution counter fixed on the headstock it makes a suitable machine for field-coil winding, the counter enabling the turns per coil to be ascertained. Suitable supply of tools for above. Small 6in. centre lathe, screw-cutting and traversing motion suitable for small brass and iron turning, etc. Vertical pillar drilling machine with swinging table and automatic feed. Small sensitive bench drill. Plain vertical milling machine, rising and lowering table, automatic feed, etc.—this machine could be used for milling, surface milling, metal sawing, and cleaning out commutator lugs, etc. Ten-inch or twelve-inch double emery grinder, grindstone, etc. Portable gantry crane for lifting work in and out of lathes, etc., and suitable benches and vices.

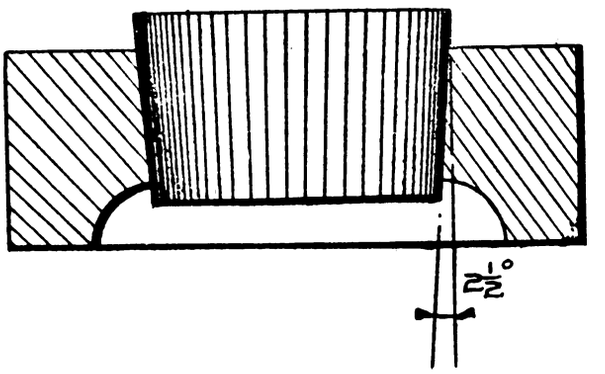
Test Room and Winding Shop.—The above shop should be kept clear from the shop dealing with swarf metal, etc, and should be equipped with the following apparatus: winding benches, cast-iron armature trestles, armature and field-coil formers, sheet-iron oven for drying and baking, heated to a temperature of, say, 100deg. to 180deg. F., and gas stoves suitable for soldering irons. All banding of armatures may be done in the lathe. A low erecting table and test bed should be constructed of about 4in. by 4in. timber, on which motors can be conveniently lifted. A small switchboard should be fixed for testing purposes near the test bed, and provided with the following instruments: ammeter, voltmeter, main double-pole switch and fuses,



Split Ring Method.

and two or three branch switches and fuses. A Wheatstone bridge should be provided, also an Evershed's 220-volt "Megger" testing set, small ammeter, and sundry instruments. The whole of the machine tools should, preferably, be driven from shafting which in turn is driven from a motor.

Commutator Construction.—It is assumed that commutators will not be manufactured in any quantity, but only for the purpose of replacing a worn-out or damaged one, therefore a large outlay will be unnecessary. The most substantial commutator is made with the aid of a hydraulic press.

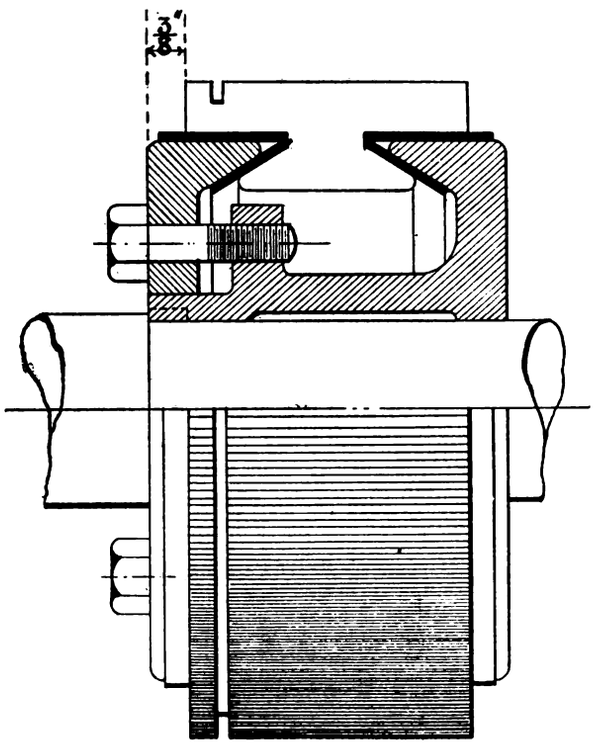


Taper Die Method.

The necessary section of hard-drawn copper strip should be obtained and sawn off to a gauge, allowing for machining, endwise, and tapered on the broad edge about 2½deg. When all the sections are assembled, with ·03in. mica between, they form a cone with the required taper for forcing into a steel die by hydraulic pressure. This die should be of steel, turned all over and bored to the same taper, the bore being just large enough to allow the small diameter of commutator to enter. The mass should then be pressed home and the complete die put in a lathe for the purpose of machining the copper—that is, turning the V for the $\frac{1}{16}$in. mica end rings and boring—the malleable sleeve and washer being tightened up and the complete

Digitized by Google

commutator removed by hydraulic pressure, fixed on a mandrel and turned up, the slotting being done between the centres of a milling machine. There are other cheaper methods of making a commutator, such as gripping the bars between a wrought-iron split collar, as shown, the whole lot being put in the lathe and machined, but it does not make such a sound job and the bars are liable to sink. A finished armature should always have the commutator ground up dead smooth by an electrically-driven emery wheel fixed in the lathe tool box. These wheels are keyed direct on to the motor shaft, and the motor can be run from an ordinary



lampholder. The sketch herewith shows the construction of a very reliable commutator if built in the manner described above.—PETER DEAN.

Answer to No. 812 (*awarded* 5*s*).—A small shop, or even a corner of the fitting shop, should be set apart for these repairs; cleanliness and tidiness are no mean adjuncts in connection with the renovating of electrical apparatus. The most essential tool is a lathe; this lathe need not necessarily be normally large enough to take the largest armatures, as iron or wooden packing pieces can be placed below the heads when these larger armatures are under repair. If the lathe is arranged for screw-cutting, *any* work connected with repairing the motors can be accomplished. It would be convenient to have two lathes, one much smaller than the other, but this would increase the first cost. A small drilling machine would be useful, but in order to keep down the first cost it can easily be arranged to do any drilling in the lathe. By means of the lathe commutators may be turned and new bands wound on the armatures, also bent spindles may be straightened and new ones turned. In the hands of a competent workman a lathe can be made to do almost anything. A number of drums and stands should be provided, so that the cotton-covered wire may be run through varnish, and thus prepared for winding on armatures or magnet bobbins. A low bench, with suitable V blocks, will be wanted for rewinding armatures. If the armatures have former-wound coils, formers should be provided for each size, and care taken to have spare coils ready for replacing faulty ones. There should also be formers for winding magnet coils: if these coils are on bobbins, there should be wooden carriers to enable the bobbins to be placed in the lathe for rewinding. Unless care is taken to support some magnet bobbins, they are liable to be forced out of shape during winding, and are thereby prevented from being slipped over the magnets. A small press will be necessary in order to repair or make new mica rings for the commutators. Iron mandrels and clips will be required to build up commutators; by means of several layers of paper or metal liners one mandrel may be made to do duty for several sizes, and in like manner liners may be used with the clips.

To build up a new commutator is quite a straightforward affair. Some considerable skill, however, is required to replace a faulty section in a fixed commutator. To perform this operation, first unsolder the armature wires from the lug of the faulty section and twist several turns of wire round the commutator to hold sections in position; then unscrew nuts and remove the outer insulating ring. By means of a thin knife then slacken and withdraw the faulty section. Replace with a new one, tighten up rings, solder in wires, and file or turn the new section down to size. Patterns for sections of the various commutators should be in the store, so that a new set of castings can be obtained immediately if required. A small forge and anvil for iron work, also means for heating soldering irons, must be provided. A testing set for measurements and a linesman's detector should also form part of the kit. If there are any white metal bearings, a stock of metal, with pot and ladle, will be necessary for re-running bearings. Another item will be a fitter's bench; this should be provided with two vices, one a strong, 6in. the other a small vice for light work. For repairs on the larger-sized motors a jack will be useful, also some lifting tackle. There should also be blocks of wood wedges, etc., for use as "packing" when taking out and in the heavy armatures. An assortment of screws and bolts, brass and iron rods, ebonite, mica, armature and magnet wire, solder, etc., should be in the store. With regard to the brushes and brush gear, endeavour should be made to keep as nearly to one type as possible, so that fewer spare parts will be necessary; try and eliminate all oddities, and replace with a common form. As to the possibility of making commutators cheaply, that is pretty much a personal equation. Have good metal patterns and obtain sound castings. To build up the commutators quickly and well demands skill, and a detailed description would make this answer too long, but "G. F." may be assured that commutators can be made cheaply with quite simple appliances. M. M.

Answer to No. 812 (*awarded* 5*s*.).—In any repair shop, such as is referred to in the above question, the choice of suitable machinery depends, to a very large extent, upon local conditions and local requirements. Thus, it is obvious that where motor repairs are not very numerous, a multiplication of appliances would lead to a dead loss—the investment would produce but little return. Whilst, on the other hand, if the repairs are numerous, it would be a distinct advantage to equip the shop with appliances which would facilitate the execution of *any* repair. Of course, the nature of the repairs required is a very important factor to consider, and it is one which should not, by any means, be disregarded.

From the above question it is inferred that the chief repairs which will have to be effected are those on the commutators of the motors, although these may not constitute all the work of the shop. In the opinion of the writer, the following are the principal appliances required in order to satisfy the conditions of the question: lathes, milling machine, drilling machine, and assembling rings. The lathes should be two in number, one being for the smaller sizes of motors, and the other for the larger sizes. The exact size of each lathe should be in due proportion to the size of the motors, or else facility will not result. The milling machine should be obtained for the purpose of tapering the copper segments for the commutators, these segments being either hard-drawn or drop-forged. The drilling machine is useful, though not absolutely essential, and it could, therefore, at a pinch, be dropped out of the list. The assembling rings are for the purpose of facilitating the building up of the commutators, because without their use, or the use of their equivalent, the process of commutator building would be a long and tedious one, and it would not be attended with the best results. Several sizes of these rings, however, must be obtained, as each size of commutator will require its own separate assembling ring. One type of assembling ring, which could be conveniently used, consists of two concentric rings of stout iron. The outer ring is a continuous, unbroken ring, whilst the inner ring is made up

Digitized by Google

of a number of segments, eight or twelve being a very convenient number. Each of these segments has a couple of pins screwed into it, which pins project outwards, and fit easily, yet not too loosely, into holes drilled in the outer ring. The assembling ring is placed horizontally, and the copper segments and mica plates are built up inside the inner ring. When all the segments and plates have been fitted in, the segments of the inner ring are forced inwards by means of screws in the outer ring. This operation naturally results in causing the copper and mica sections to fit together more closely, and the built-up commutator can then be fitted on to the spider of the armature, and the operations of insulating, clamping, and surface turning can then be completed.

Should there be much rewinding of armatures to be done, the use of formers will facilitate the operation of winding. If all the motors are of standard types, to procure suitable formers will not be very difficult.—G. W. BURLEY.

Question No. 813.—A works is supplied with current from a power station with continuous current on the three-wire system, with 500 volts between the outers. It is required to split this up further at the works, for the purpose of speed regulation of the motors driving the various machines, by means of "shunt" or "shunt" and "armature" regulation combined. The voltages proposed are as follows: between outers 500 volts, between outer and middle wire 250 volts, between middle and intermediates 60 volts, between intermediates and outers 180 volts, which would enable the motors to be supplied with voltages of 500, 310, 250, 180, and 60. Show clearly how this could best be done. Further, would it be to the advantage of the company owning the works to put down their own generating plant for lighting and power, and, if so, what arrangement of generator would be best to adopt, without the use of balancers?

Answer to No. 813 (*awarded 7s. 6d.*).—It may be as well to point out that the voltages as mentioned in the question cannot be obtained, since the sum of the voltages between neutral and intermediate and intermediate and outer must equal that between neutral and outer. If the first-mentioned voltage were 70 (instead of 60), the condition would be fulfilled, since 70 + 180 = 250. Assuming 70 volts to be the correct figure, the simplest method of splitting up the voltage is to instal a dynamo giving continuous current at 140 volts. This machine should also be provided with slip-rings connected to the windings, so that it can give off three-phase current. These slip rings are connected to a suitably designed choking coil star connected, the centre point of the star being connected to the neutral 'bus bar, as shown in Diagram 1. The method of driving the dynamo is immaterial—a small steam-engine or electric motor could be used, or even a second winding for 500 volts wound on the same core and connected to 'bus bars. In this case, however, the machine would require two commutators, and probably the best method is to drive by an independent motor. The capacity of the dynamo will, of course, depend on the number of machines supplied by it at any time. With the connection shown on Diagram 1, voltages of 70, 140, 180, 250, 320, and 500 could be obtained, the current obtaining a return circuit through the choking coil and slip-rings of the dynamo in the case of the voltages 70, 180, or 320.

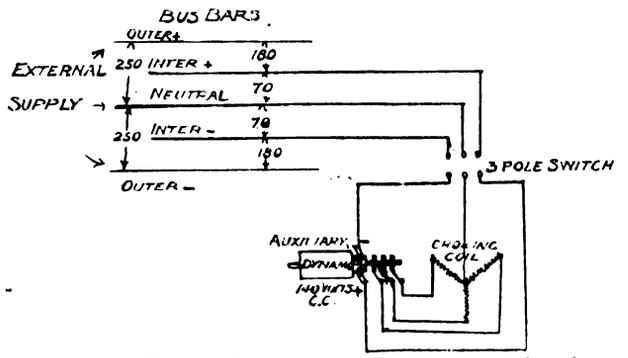


DIAGRAM 1.—Dynamo, 140 v. c.c., 91 v. three-phase. External supply, three-wire c.c., 500 v. outers.

The question of private generating plant depends entirely on the prices at which the works could produce or buy power. Many modern works produce their own power at will under 1d. a unit with a moderately good load factor, this price covering interest and depreciation. If the company installed their own plant, it would be best to instal a dynamo with two independent windings on the same core, one giving 500 volts, one 140 volts, etc. Each winding would also have independent slip-rings, and these would be connected to suitable points on the choking coil, as in Diagram 2. If more than one generator was running at once, each one should have an independent choking coil, with neutral connected to neutral 'bus bar, as this would save synchronising the generators with each other. The generators could be driven by any convenient source of power, and would, of course, have to be paralleled on the continuous-current sides. A very similar method of supply to the ones described has been installed by a firm in the North, and is used to supply motors driving machine tools, etc. There are various other combinations of the same principles which can be used to attain the same results, but the methods described above are, perhaps, the simplest, and require the least outlay in plant.

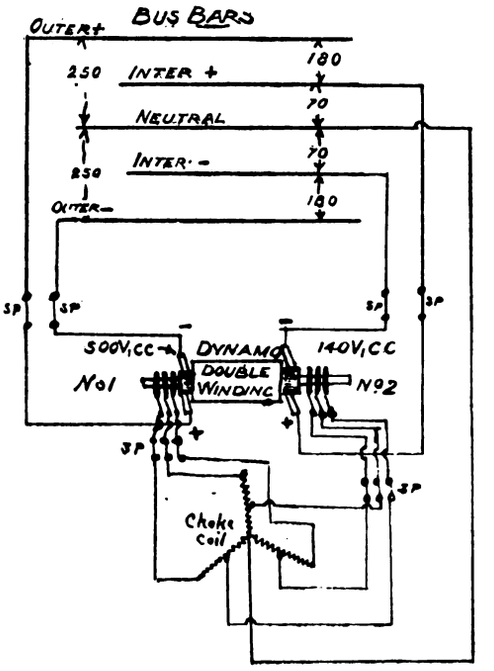

DIAGRAM 2.—No. 1 winding, 500 v. c.c. and 325 v. three-phase; No. 2 winding 140 v. c.c. and 91 v. three-phase. Single shunt-wound field excited any convenient way.

It must, of course, be understood that the function of the three-phase choking coil is to take the out-of-balance current only, so that the capacity need only be small. The explanation of the choking coil's action in passing the out-of-balance continuous current has already been dealt with in Question No. 745, which appeared in these columns some months ago.—ROTARY.

Answer to No. 813 (*awarded 7s. 6d.*).—In this question the problem set is to convert a three-wire system into a five-wire system. Such five-wire systems are often used with printing machinery on a small scale, and, of course, on a large scale at Manchester. There are two methods by which the voltage may be sub-divided at the works: (1) By using a five-wire balancer consisting of four machines all on the same shaft and wound for the voltages given. This balancing arrangement is shown in Fig. 1. (2) By using a battery of about 300 cells. (This is the number our company use for working a large shipyard.)

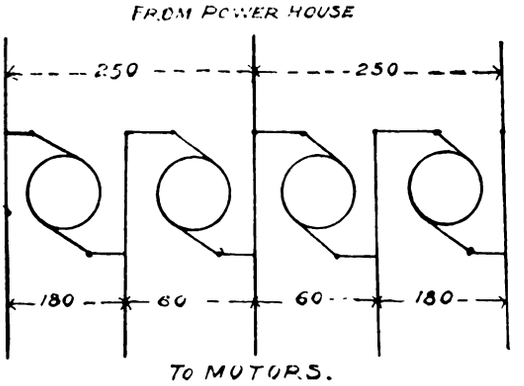

FIG. 1.

Digitized by Google

These cells are tapped in the requisite manner for supplying the voltages desired.

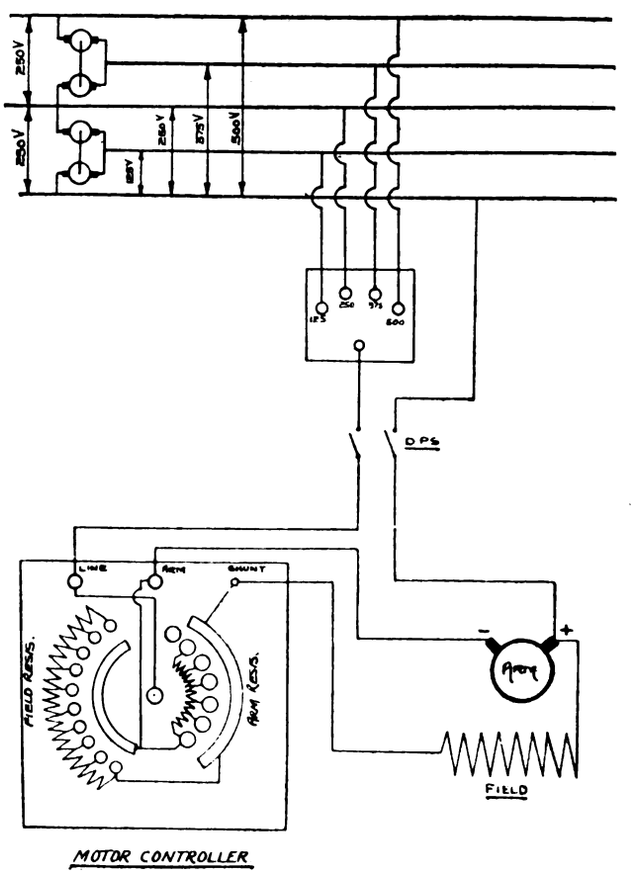
Either of the two above methods will do as far as working is concerned. The battery will, of course, cost more than the balancers. I think, however, that the other conditions of the question will help to decide this. The point now to be decided is, should the company owning the works put down its own plant for lighting and power, or take it from the power company? I note that before the change is made to the five-wire system they are taking it from the power company, and not generating it themselves. This point cannot be decided one way or another without further data on the subject. It depends entirely on the local conditions, a few of which I have enumerated below. They all decide the price at which the power company will supply the power: (*a*) the amount of power taken by the works; (*b*) the load factor. This will depend on whether the works run all night or not—a very important point, indeed.

It appears, however, that the price of the power is fixed, and that unless large extensions have taken place, which will increase the amount of power taken, the price of power will not be altered. Now, if this price be high, it may pay the works to put down their own plant, but not unless, and even then I do not think it would pay them unless they took a fairly large amount. Let us consider a hypothetical case. Suppose the works took an average load of 400 amperes at 500 volts = 200 kw. This would be a fairly large works. They should get their power for a comparatively small amount, say $\frac{7}{8}$d. per unit. I do not think that they could generate it themselves at less than 1$\frac{1}{4}$d. to 1$\frac{1}{2}$d. per unit, and I think that, except under exceptional circumstances necessitating an exceedingly high charge by the supply company, it would not pay the works to generate it themselves. Now, in my opinion, it would pay the works to put down a battery for sub dividing the voltage as required. There are two reasons for this. The first of these is this: during the winter months the works load and the lighting load would overlap at the power station. Now, if the works company put down a battery they could discharge it during these times of maximum load at the power station. They could then make an agreement with the power company not to take any power during these times, all the power being taken from the battery, which would thus perform a double purpose. The power company would then reduce their price of power—it would pay them to have this arrangement, and without the slightest doubt they would be very pleased to do it.

The second reason why it is better to instal a battery is that it would come in useful during a "shut down" at the power station. These happen even in the best-appointed places, especially on high-tension systems, and they are very costly, since they lay the whole works idle until the power is put on again. Indeed, I know of a case in which the main reason for installing a battery was to keep the works going during any "shut down" which might occur. I think, therefore, that it will pay the works to take the power company under the conditions given above, and use a battery for sub-dividing the voltage, running the works off the battery during times of maximum load at the power-house, and thereby obtaining a reduction in the price of the power. An attempt should be made to get the power company to put down the battery themselves, and, all things being considered, I think they would do it for only a small increase in the price of the power.—ERNEST P. HOLLIS.

Answer to No. 813 (*awarded* 5*s.*).—The speed control of electric motors is a very interesting subject, and has been widely discussed by many engineers both in England and America. Should the interested party require valuable information upon this subject, I would refer them to some papers read at the meetings of the American Institute of Electrical Engineers, contained in vol. xx, 1902, of the *Proceedings*. I note that the works in question possess a 500-volt three-wire supply, and require further subdivision, but I do not see how this can be accomplished without the aid of balancers in some form or other. It practically amounts to a five-wire distribution with uneven voltages—namely, 500, 320, 250, 180, and 70 volts—and specially-wound balancers or storage batteries would have to be used.

The diagram herewith represents a five-wire system with standard voltages—viz., 125, 250, 375, and 500 volts—these being obtained by using two balancers as shown, all intermediate speeds, both up and down, being secured by armature and shunt regulation with the special controller. Care must be taken to see that the motors will stand an increase of speed by field resistance without sparking. It is generally agreed upon that speed control by ohmic resistance in the armature circuit is very wasteful, and should be avoided wherever possible. I believe a more suitable method of attaining the same end is to instal variable-speed motors, with a 2 to 1 speed ratio, across a three wire system, and obtain intermediate steps with field regulation only. A 4 to 1 ratio is thus secured without any C^2R loss.



MOTOR CONTROLLER

The method of connecting will be as shown in sketch, except that three wires are used in place of five. The motors should be evenly distributed on either side of the system, and in the case of outside supply the necessary balancers will be located at the generating station. Very satisfactory motors with a 2 or even 4 to 1 ratio of speed may be obtained, and I believe the extra outlay on these would come well under the cost of installing a complicated five-wire system throughout the works, together with balancers. In addition to the controller, a switch for connecting the various circuits to the motor must be used; also a double-pole main switch. It will be noted that no overload or "no-voltage" attachment is shown on the controller, but these may, of course, be added if required.

With reference to the latter part of the question, as no figures whatever are given, it must be left to the owner to decide whether or not he will instal his own generating plant, bearing in mind that a large reduction in the price of energy can be secured for an all-day load. Should a much finer speed variation be required, the well-known Ward-Leonard or teaser system of motor control might with advantage be considered.—P. DEAN.

[Other replies to Question No. 813 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

QUESTIONS.

821. In a certain power station it is desired to test a 700-kilovolt-ampere two-phase alternator, direct coupled to a triple-expansion Belliss engine, for the steam consumption—*i.e*, pounds of water—per kilowatt-hour. There is available a water resistance capable of taking 1,200 kw., if required. The set has its own condenser—steam-driven air and circulating pump. There is a feed tank 12ft. by 7ft. by 6ft., into which several condensers discharge, the temperature being from 80deg. to 120deg. F. The feed to the boilers being pumped from this tank through an economiser to the boilers (Babcock and Wilcox. Meldrum Koker stokers, and forced draught), the steam for the jets can, if necessary, be supplied from an independent boiler. It is not required to take into account the steam used by the condensing plant. It is proposed to run the test for five hours. Is this long enough? Please give full details of the usual method of conducting such a test, especially the best way of measuring the water at the hot-well, the various readings required, etc. Also name any good practical books dealing with engine and boiler tests (not American). The steam pressure at the engine stop valve is 170lb. with about 100deg. F. of superheat.—ELECTRON.

ANSWERS.

Question No. 813.—A works is supplied with current from a power station with continuous current on the three-wire system, with 500 volts between the outers. It is required to split this up further at the works, for the purpose of speed regulation of the motors driving the various machines, by means of "shunt" or "shunt" and "armature" regulation combined. The voltages proposed are as follows: between outers 500 volts, between outer and middle wire 250 volts, between middle and intermediates 60 volts, between intermediates and outers 180 volts, which would enable the motors to be supplied with voltages of 500, 310, 250, 180, and 60. Show clearly how this could best be done. Further, would it be to the advantage of the company owning the works to put down their own generating plant for lighting and power, and, if so, what arrangement of generator would be best to adopt, without the use of balancers?

Answer to No. 813 (*awarded 7s. 6d.*).—In this question neither the size of the works nor the kind of work turned out is mentioned, but it is evident that variable-speed continuous-current motors are considered necessary. The voltages into which it is proposed to divide the present 500-volt supply will allow of obtaining 500, 310, 250, 190, 120, and 60 volts. From Table I. we see that a minimum of 12 per cent. of the total voltage is obtainable. The difference in the voltage in changing from one step to the next is shown in the third column, and is expressed as a percentage:

	Voltage on the motor.	Per cent. of total voltage.	Difference of percentage for each controller step.
Table I.	500	100	
			−38
	310	62	
			−12
	250	50	
			−12
	190	38	
			−14
	120	24

This, however, entails a five-wire distribution. The Bullock Company, of America, use a four-wire system with balancers, as shown in Fig. 1. The voltages obtained are shown in Table II. By this means a minimum of 16 per cent. of the total voltage is obtainable, and the steps are more equal throughout than in Table I. Moreover, there are only four wires used, as shown in Fig. 1. A proportionate division of the voltage can be made on the 500-volt system, but the figures obtained are not standard voltages. These multi-voltage systems, however, have the disadvantage that the switching arrangements are complex, and, further, that there is a danger of the machine slowing up whilst the motor is being switched from one voltage to the next. With "armature" or "series" regulation the speed of the motor will be high before the tool gets on the work, and will be lower when the tool is cutting. This is due to the voltage drop on the series resistance, which voltage drop varies with the load on the motor. These difficulties do not occur with shunt-controlled motors, which can be obtained with a speed variation down to 25 per cent. of the maximum, the efficiency varying 6 per cent. or less throughout the range at a constant power output. The rise of speed on such a motor would be 6 per cent. or less when the load was thrown off. Speed variation in this way can be obtained down to 17 per cent. of full speed. The points mentioned above have a bearing on the choice of a generator, but the primary consideration is the kind of work turned out of the shops, as this will determine the type of motor, which in its turn determines the type of generator. If the works be large, it is possible that there is a sufficient number of machines requiring a constant speed drive to warrant putting in an alternate-current supply and using induction motors. Speed variations are not obtained as efficiently on these as on the continuous-current shunt-controlled motors. In dusty places, or in an explosive atmosphere, a squirrel cage open-type motor may be employed. An enclosed continuous-current motor working under these conditions would be large for its output. In Messrs. Harland and Wolff's shipyard, owing to the various types of drive required, both continuous-current and alternate-current supply have been put down. The device is also adopted of having an engine to drive an alternating-current and continuous-current generator on

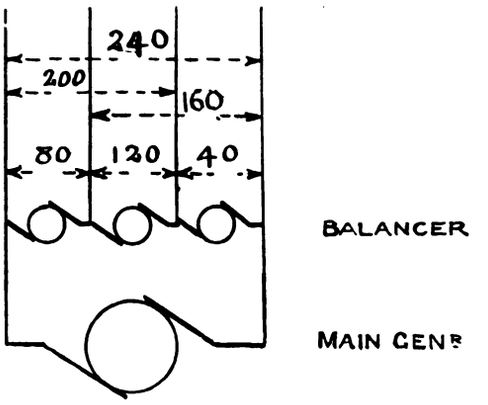

FIG 1.

the same shaft. There is also a synchronous motor-generator, which links together the continuous-current and alternating-current systems. When only the alternating-current generator is working, the motor-generator is driven from the alternating-current side, and supplies the small amount of continuous current required. When the continuous-current generator is working, the opposite conditions obtain. This arrangement is adopted, since at times of small demand the total alternating current and continuous current required may not be more than that which it is possible to supply from one engine. There are two engines arranged as above, and the third drives an alternating-current generator. As to whether it would be to the advantage of the company to put down its own plant for lighting and power, it may be mentioned that there are cases in which the saving due to electrical driving has been more than sufficient to pay for the lighting required. As the works are already built, there can be no saving in the actual fabric, but it should be borne in mind for future extensions that electric driving does not call for the heavy walls required by shafting transmission. This brings up the question of "individual" or "group" driving of the tools. No hard-and-fast rule can be laid down to cover all cases, but it is evident that with the individual drive, in which one motor drives one machine, the speed and output are independent of any other machine, and it may be worked up to its full capacity.

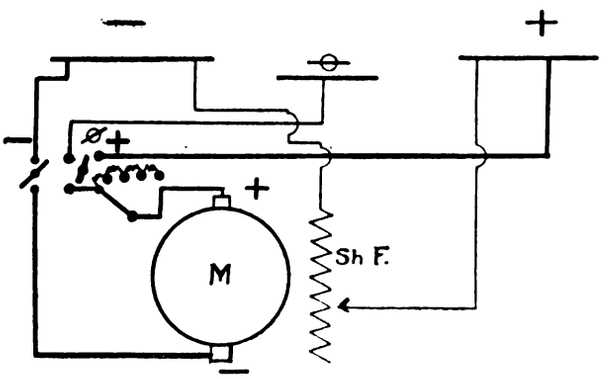
In "group" driving it is advantageous to group together on the one countershaft machines of the same size, speed, kind of work, etc. Seeing that the 500-volt supply is now available in the works, it is probable that the load factor is known, and this would form a basis in deciding as to the size of generators required. In deciding on the motors for individual or group driving, it is convenient to use a test

Digitized by Google

motor which is moved about from tool to tool. In this way, with the help of a recording ammeter and meter, much useful information can be obtained, which will prevent a motor being supplied which is either too large or too small for its work.

The above considerations should help to settle the question regarding the plant required, whilst actual details of the supply company's price for current and the cost of generating same in the works should settle the question as to a separate plant being put down.—L. S. S.

Answer to No. 813 (*awarded* 5*s.*).—The method of obtaining the speed regulation suggested by "Motor Control" is quite too complicated to be entertained. All that is desired can be now obtained by using the ordinary three-wire system, which, in addition, is far cheaper to instal and run than any multiple-wire system such as that described. If more particulars had been given as to the class of machinery it is required to drive, it would have been possible to give a definite scheme; as it is, only a general idea of what is best to use under certain conditions can be given. It is now found to be more economical to divide the machines to be driven into two classes: (1) those machines which run at fixed speeds not often varied, and (2) those machines requiring varying speeds and which require full power at all speeds. The first class are then driven from line shafts by a single (or according to the number of machines) or more motors, and are placed where head-room and space for operating overhead cranes is not required. The second class are run by separate motors to each machine, which may be placed anywhere it is convenient, and whose speed regulation is obtained by varying the field strength of the motor. The accompanying diagram shows the idea and



the method of obtaining the speed regulation. The positive neutral and negative bars are connected as shown to the main switch of the motor, M, and it will be noticed that one arm of the double-pole switch can be connected to either the neutral or positive side of the system. Sh. F. shows the variable shunt field. Now, suppose the motor to run normally at, say, 900 r.p.m. with full field strength and its armature connected across the outers, it will then run at 450 r.p.m. with full field strength and its armature across the one outer and the 'mid wire. Now weaken the field and bring the speed up to 900 r.p.m. again, when the armature can be switched across the outers, and the fields again strengthened to keep the speed at 900; and from this point it will be possible to weaken the field enough to bring the speed to 1,900 r.p.m., or even more, without causing destructive sparking. And it is due to the fact that motors can now be built to run between such wide limits of speed simply by varying the field, and at the same time not incurring the risk of sparking, that the old multiple-voltage system and methods of working with resistance permanently in the armature have been rendered unnecessary. As to it being more economical to generate power on the premises than buy it, as stated before, not enough data have been given to give a definite answer. If there is a steady load for eight or ten hours per day, and the demand is anything over 50 kw., a modern installation driven by gas-engines working from suction producers will, if the proper type of engine is used, give very economical results. Some tables of results actually obtained over prolonged periods of running, which I have by me, show the cost per unit generated to be as low as ·25d., including all charges, such as attendance, depreciation, etc., this being with plant of units of 30 kw. capacity and upwards. There would also be another advantage in having a separate generating station—viz, that the system could be operated at a lower voltage if the works did not cover a very large area, and motors of small capacity, wound for 250 volts or higher, are very much more liable to give trouble and have a lower efficiency and higher capital cost than motors wound for, say, 220 and 110 volts.—W. T. W.

Question No. 814.—In the brake equipment of tramway rolling-stock, the present tendency is to put the brake blocks below the centre of wheel. Why is this so? And if the brake has more power in the lower position, explain the reason.

Answer to No. 814 (*awarded* 7*s.* 6*d.*).—The great aim in the design of brake equipment is to obtain the greatest brake power in the shortest time. Herein lies the reason for having the brakes fixed on the top of the wheel. First of all let us imagine the brakes to be fixed on the top of the wheel. This, of course, is never likely to happen, but on second thought it will be seen that it is only an exaggeration of the principle of having the brakes fixed above the centre. It will readily be seen that if the brake is applied it will tend to lift the car from the axle, and on this being done the power is at an end. Screwing the brake any further would just be simply raising the car. Again, when the car is travelling the springs are compressed, and before power of any consequence can be applied on the wheel, this compression must be taken off. This would mean the car being raised at least 2in., while the motorman would be thinking he was grinding a street organ.

Let us now look at the matter with the brakes fixed below the centre. It is a well-known fact that a man can exert more power by pulling against himself than merely allowing his own weight to be the power. Although a man is not a tramcar, the same principle applies. When the power is applied from the car to the under portion of the wheels, it tends to bring the car and wheels close together, and when this is done, still greater power can be applied according to the multiplying mechanism. Again referring to the springs being compressed by the weight of the car, when the power is applied underneath the wheels it tends to still further compress the springs, and when this compression begins it will be seen that the power is equal to the weight of the car, additional power being applied at will. It is practically impossible to apply the brake to the centre of the wheel, as the oscillation of the car and the direction in which the wheels are running would alter its position to either above or below the centre. The brake power should be nothing less than 100 per cent. of the weight of the car unloaded.—C. W. G.

Answer to No. 814 (*awarded* 7*s.* 6*d.*).—The chief drawback in tramway rolling-stock having the brake blocks placed above the centre of the wheels is the trouble that ensues from the vibration of the car when the brake is applied. When the blocks are in this position and pressure brought to bear on them, it transmits the whole weight of the car from the springs on to the brake-block hangers, forming a rigid connection between the body of the car and the wheels, and subjecting the car to all vibration and shock due to inequalities of the tramway. This soon causes heavy wear and tear on the motors, gearing, etc., besides severely straining the brake gear, rendering risk of fracture imminent. By placing the brake blocks below the centre of the wheels this defect is avoided, as the weight of the car is still on the springs when the brake is applied; and when the springs are compressed by the oscillation of the car the tendency of the brake block is to leave the wheels for an instant, thus giving great elasticity between the body of the car and the wheels, and gaining the full benefit of the springs.

There is no gain in power by placing the brake blocks below the centre of the wheels; to gain power we would have to alter the mechanical advantage of the brake levers. A simple way of finding the pressure on the brake blocks of a hand-brake is to determine the ratio the brake wheel at which the power is applied bears to the brake blocks, and multiply this ratio by the force in pounds exerted on the wheel. This gives the total pressure in pounds on the brake blocks, neglecting friction. For example, suppose a brake wheel 16in. diameter is so connected to the

Digitized by Google

brake blocks that during 10 revolutions of the wheel the blocks move through the space of 1in. The ratio between wheel and blocks will be $\frac{16 \times 3{\cdot}1416 \times 10}{1} = 504$ to 1. This multiplied by the force exerted on the brake wheel, say 30lb = 15,120lb. total pressure on the brake blocks.—GEORGE EMENS, JUN.

Answer to No. 814 (*awarded* 5*s.*).—The principal reason for fitting the brake blocks below the centre of the wheel is to obtain the maximum braking effect for a given pull

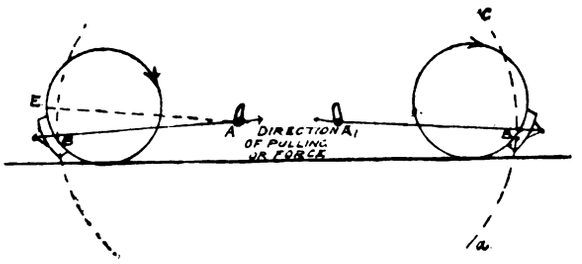


FIG. 1.

on the rods. In Fig. 1 is shown diagrammatically and to scale the relative positions of the wheels, blocks, and rods as they exist on a particular truck. The wheels are supposed to be rotating in a clockwise direction, and the brakes are pulled up to the wheels by a force acting at points A and A_1, and in a direction indicated by the arrows. It will be evident that the wheel to the left will tend to draw block B towards point E. Now the distance A – E is greater than A – B, and as the point A is fixed by the pull exerted there to pull on the brake, any movement of the block towards E must necessarily cause the pressure on the wheel to increase, and so help the braking of the car. Now in the case of block B_1, the rotating wheel will help to throw the block away from the rim, and cause it to move in the circle $c-d$, with A_1 as centre, thus increasing the distance between the block and the wheel. It will now be clear that a certain amount of force will be used up in overcoming the centrifugal force exerted on block B_1, that there will be an increase of braking effort on block B due to the centrifugal force there, and the net result will be in proportion to the pull on points A and A_1. When the wheels rotate in the opposite direction, block B_1 behaves exactly similar to block B, and *vice versâ*.

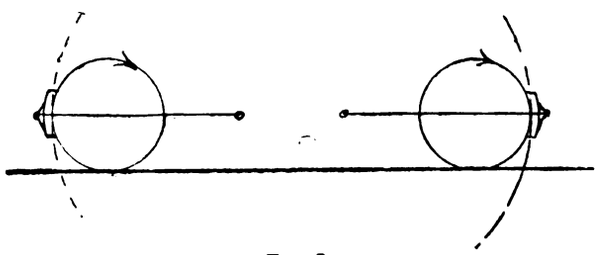

FIG. 2.

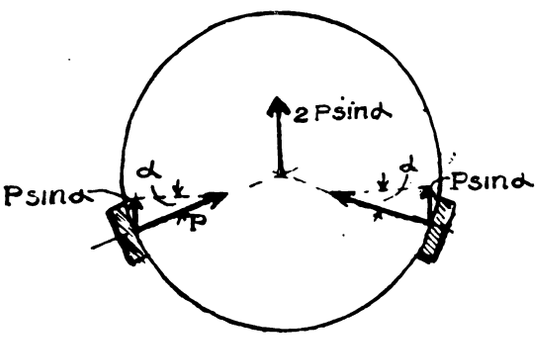
In Fig. 2 the blocks are shown fitted at the centres, and it will be seen that whichever way the wheels are revolving the blocks will tend to move in the circles shown by the dotted lines, and *both* blocks will be carried away from the wheel, so that a larger proportion of the force acting through the rods will be required to overcome centrifugal force than when the conditions are as represented in Fig. 1.

With the blocks so hung advantage is also taken of the force of gravity to assist the pulling-off springs in keeping the blocks off the wheel when the brakes are out of action, although this depends upon the point from which the blocks are suspended. Again, if the blocks were on or above the centres, and a portion of the block broke away, it would be liable to be carried into the under-gear, and thus cause considerable damage.—E. T. A.

Answer to No. 814 (*awarded* 5*s.*).—The braking power will be slightly increased by placing the brake blocks below the centre of the wheel, as can be seen from the accompanying diagram. Let P be the pressure exerted by each block against the wheel, then the axle will press against the top half of the bearing with a force 2 P sin α (sum of the two vertical components of forces P), in addition to the pressure exerted by the weight of the car. This will increase the friction between the axle and the bearing, and, therefore, the braking power. Let R be the radius of the wheel, u_1 the frictional coefficient between blocks and wheel. Then if the blocks are placed on the horizontal centre line, the braking effect will be

$$2 \, P \, R \, u_1.$$



Let r be the radius of the bearing, and u_2 the frictional coefficient between axle and bearing. Then if the blocks are placed below the centre, the braking effect will be

$$2 \, P \, R \, u_1 + 2 \, P \, r \, u_2 \sin \alpha.$$

Increase of braking effect per cent.

$$100 \, \frac{r}{R} \times \frac{u_2}{u_1} \times \sin \alpha.$$

Taking, for instance, R = 15in., r = 2in., $u_1 = {\cdot}18$, $u_2 = {\cdot}06$, α = 10deg.

$$100 \times \frac{2}{15} \times \frac{{\cdot}06}{{\cdot}18} \times {\cdot}17 = {\cdot}76 \text{ per cent.}$$

The increase in the braking power would be less than 1 per cent., therefore hardly worth troubling about.—ALTERNATOR.

Question No. 815.—I want to make a solenoid that will operate the starting lever of a clock mechanism. The lever has to be pulled through a distance of ⅜in.; pull required, 1½lb. Is it practicable to make such a solenoid to operate from a few cells? Solenoid and plunger to be kept as small as possible. The starting lever could, perhaps, be lengthened so as to reduce the pull required, but, of course, the distance it would have to be moved through would be increased proportionately.

Answer to No. 815 (*awarded* 7*s.* 6*d.*).—The subject of designing solenoids to give a predetermined pull has been very fully discussed in recent articles in the American technical Press (*American Electrician*, March and July, 1905, and *Electrical World and Engineer*, May 20, 1905). Following on the lines indicated in these articles it is possible to design a solenoid to give a 1½lb. pull through a ⅜in. distance when worked by a few cells, although these will have to be of the small accumulator type.

It is found experimentally that the "stopped" solenoid is the best type to be employed, either with or without a coned plunger and recessed stop. This latter arrangement merely tends to make the pull more even over the whole distance of travel, but does not increase the initial pull. The different parts should be proportioned as follows: (*a*) the mean path for the flux in the yoke should not exceed two times the length of the path in the core and plunger when the latter is right in against the stop, otherwise the plunger travel is so small in comparison with its diameter that an ordinary electromagnet would do; (*b*) the neck of the solenoid through which the plunger travels should be about 2½ times the diameter, so that the magnetic reluctance at this point is low compared with the main air-gap—the brass bushing around the plunger should be about $\frac{1}{16}$in. thick; (*c*) a small brass plate $\frac{1}{16}$in. thick is necessary between the plunger and core to make the magnet release quickly when the current is cut off. After these preliminary considerations, we proceed to find the number of ampere-turns necessary for different plunger lengths, and then can calculate the diameter of the plunger to give the required pull.

The plunger should be made of good machinery steel, and this requires about 470 ampere-turns per inch of length for B = 120,000 lines per square inch. The yoke should be

Digitized by Google

of cast steel, and requires about 15 ampere-turns per inch of length for B = 120,000 lines per square inch. The air-gap between the ends of the plunger and core will require 2,350 ampere-turns when the plunger is "home," and the annular air-gap 235 ampere-turns under similar conditions. The total excitation, therefore, to produce a magnetic density of 120,000 lines per square inch in the plunger when it is against the buffer plate will be $2,585 + 500\ l$, or, say, $2,600 + 500\ l$, where l = length of core and plunger path.

By assuming trial values for the length, l, we find the necessary ampere-turns as tabulated below:

Length of plunger and core.	Ampere-turns required.
1·5in.	3,350
1·75in.	3,475
1·875in.	3,538
2in.	3,600
2·125in.	3,662
2·25in.	3,725
2·375in.	3,788
2·5in.	3,850
2·75in.	3,975

From these values of the ampere-turns we can calculate the pull in pounds by a formula given by C. R. Underhill in the *Electrical World and Engineer* for May 20, 1905:

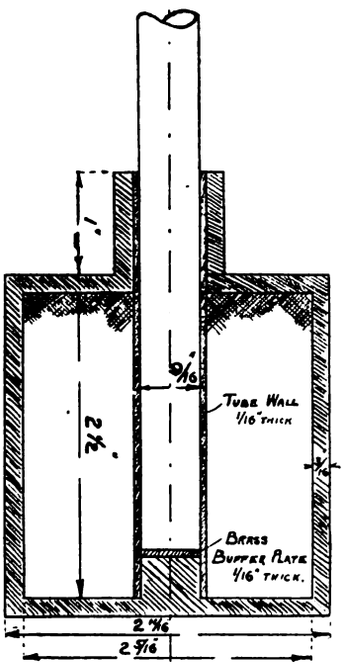
Pull in pounds

$$= \text{area of plunger} \left\{ \frac{(\text{A.T.})^2}{7,075,600\ l^2} + \frac{P_o(\text{A.T.} - n)}{10,000 - n} \right\}.$$

Where P_o = pull at 10,000 ampere-turns and one square inch of plunger and n = ampere-turn factor given in table below, L = length of winding and l = distance of travel.

L	P_o	n
1	33	3,660
2	28·3	3,150
3	23·4	2,800

If we take a diameter of plunger of ·55in., or about $\frac{9}{16}$in., and length of coil 2½in., we find from above formula that the pull is 1·7lb., which leaves a safe margin of 0·2lb. The dimensions of the solenoid would then be as shown in



the sketch, and the only remaining item is to settle on the size of wire to be employed. This is calculated as follows:

The resistance of the coil = mean length in feet × turns × ·8 × 10^{-5} ÷ section in square inches.

$$\therefore \text{the section of wire} = \frac{l_m \times T \times \cdot 8 \times 10^{-5}}{\text{resistance}}$$

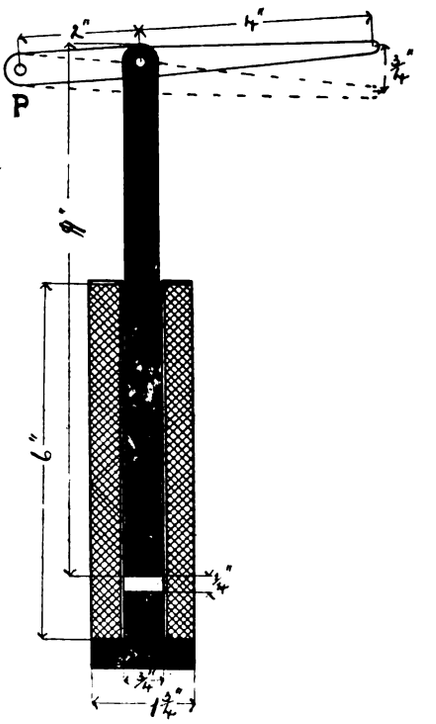
$$= \frac{l_m \times \text{ampere-turns} \times \cdot 8 \times 10^{-5}}{\text{volts across coil}}$$

(since C = E/R)

$$= \frac{0{\cdot}39 \times 3,850 \times \cdot 8 \times 10^{-5}}{6} = \cdot 002.$$

This is on the assumption for battery of cells with total voltage = 6 volts. Using No. 17 S.W.G., the coil consists of 518 turns, or 14 layers of 37 turns per layer, and has a resistance of 0·675 ohm. To excite this coil, three small accumulators would be necessary, as it would be found practically impossible to do so from ordinary dry cells. If the pull were decreased and the distance of travel of the plunger increased in a like proportion, the length of the coil would have to be increased, with the result that more ampere-turns would be necessary; the desired result would be then still more difficult to obtain. If the pull be increased and the distance of travel be decreased in like proportion, it will be found on substituting the figures in the formula given above that the diameter of the plunger will be slightly decreased, but the ampere-turns will not be appreciably decreased, and the solenoid itself will not be so well proportioned.—F. H. P.

Answer to No. 815 (*awarded* 5*s.*).—To make such a solenoid is quite feasible, and any number of different combinations might be devised to effect the purpose. The arrangement of solenoid and plunger shown in sketch, with the aid of two secondary cells, will give the necessary motion. The movable core is of soft iron, $\frac{5}{8}$in. in diameter and 9in. in length. The bobbin is made of brass, but the bottom cheek is of soft iron; part of this piece of iron enters the solenoid and forms a fixed core. This fixed core greatly increases the pull obtained. With a solenoid the great difficulty is to get a pull through any considerable distance, therefore it is best to have the core moving through as small a space as possible. In this case the core is given a movement of ¼in. in the best position relatively to the winding, this movement being multiplied by three by means of the lever working round the fixed point, P. The other end of lever will, therefore, move through a distance of ¾in., the amount of displacement specified in the question. The coil consists



of six layers of 80 turns each of No. 18 S.W.G. double cotton-covered copper wire; this winding will have an approximate resistance of ·8 ohm. Two cells will be required to provide the energising current; these cells should be of such a size as to have a discharging current of four to five amperes. It would be impracticable to so arrange matters that a small pull should take place through a longer distance; with a solenoid, as with an ordinary electromagnet, the pull falls off enormously with only a small increase in distance.—M. M.

[Other replies to Question No. 815 will be given in our next issue.—Ed. *E. E.*]

Supplement to "The Electrical Engineer,"
OCTOBER 20, 1905.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

822. It is desired to work the bellows of a church organ by a single-phase motor. Describe the best way of doing this, and sketch the automatic starting and regulating switch. The motor would require to be of about 1 h.p.—J. A. M.

823. In a station with which I am connected there is installed a turbo-generator with compensating coils in series, with the armature wound in slots in the pole faces. The object of these coils is to enable the machine to commute sparklessly with a fixed position of the brushes at all loads. Will someone please explain exactly how this is effected?—J. P.

ANSWERS.

Question No. 815.—I want to make a solenoid that will operate the starting lever of a clock mechanism. The lever has to be pulled through a distance of ¾in.; pull required, 1½lb. Is it practicable to make such a solenoid to operate from a few cells? Solenoid and plunger to be kept as small as possible. The starting lever could, perhaps, be lengthened so as to reduce the pull required, but, of course, the distance it would have to be moved through would be increased proportionately.

Answer to No. 815 (*awarded 7s. 6d.*).—No, I am afraid it will not be possible to operate the starting lever from a solenoid supplied by a few cells. In the first place, I must express surprise that a clock mechanism should require such a large pull as 1½lb., and unless this pull be considerably modified the operation by means of a solenoid will be out of the question, as I will now proceed to show. Prof. S. P. Thompson read before the International Electrical Congress at St. Louis a paper on "The Predetermination of the Plunger Electromagnet," in which he gave the formulæ I have used below.

If the magnetic circuit of the solenoid is of good iron and completely closed except for an air-gap of length 2in., the pull in pounds is

$$P = B^2 A/72{,}134{,}000 \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where A is the cross-section of the iron in square inches, and B is the flux per square inch. Further,

$$B \times 2 \times 0{\cdot}3138 = C S \quad . \quad . \quad . \quad . \quad (2)$$

where C is the current in amperes exciting the solenoid, and S is the number of turns. C S, is therefore, the ampere-turns. We can now substitute the value given in the question for P—*i.e.*, 1½lb. in equation (1). We also require a value for the cross-sectional area of the core. To keep the flux down we must make A as large as possible, but, of course, by increasing A we increase the dimensions of the solenoid. The maximum value of A which can be allowed is, I think, one-quarter of a square inch. It will be seen that if we make A very large we shall require more wire on the solenoid, and, therefore, increase its resistance. Substituting these values in equation (1) we get

$$\tfrac{3}{2} = B^2 \times \tfrac{1}{4}/72{,}134{,}000$$
$$B^2 = 432{,}804{,}000$$
$$B = 20{,}800 \text{ lines per square inch.}$$

Now, of course, we must keep the air-gap as small as possible. This is done by arranging things so that at the end of the ¾in. stroke the plunger is just at the bottom of the solenoid, and then at the beginning of the stroke the air-gap will be the least possible—*i.e.*, ¾in. Substituting the values above for B and 2 in equation (2) we get

$$C S = 20{,}800 \times {\cdot}75 \times {\cdot}3138$$
$$= 4{,}888 \text{ ampere-turns.}$$

The question states that the starting lever could, perhaps, be strengthened to reduce the pull. Suppose we double the length of the lever, and, therefore, halve the pull. We require one-quarter the flux but twice the stroke, therefore we require one-half the number of ampere-turns—*i.e.*, 2,444. It will be practically impossible without having an enormous solenoid to have 4,888 ampere-turns even with a large number of cells. I think, however, it is possible to increase the lever to twice its length so that we require only 2,444 ampere-turns to construct a suitable solenoid, though even then it will be a large one. However, I will calculate it out.

First of all we must find the inside diameter of the solenoid. The area of the core is first found. Area $= \pi r^2$;

$${\cdot}25 = \frac{22}{7} r^2; \quad r^2 = \frac{7}{88}; \quad r = {\cdot}3, \text{ nearly.}$$

We may take the inside radius of the solenoid as ·35in. This allows for the inside casing. A suitable wire will be No. 21 S.W.G. The number of turns per linear inch with this wire is 23·8, and its resistance is ·0007786 ohm per linear inch. Now let us suppose we can get from our cells two amperes, then the number of turns required = 1,222. Suppose we make our solenoid 6in. long. We then have to wind our solenoid with $\frac{1{,}222}{6 \times 23{\cdot}8}$ = say nine layers of wire, each layer containing 24 turns. The outside radius of our solenoid will be ·35 + 9 × diameter of wire = ·35 + 9 × ·042 = ·69in. The mean radius of each turn

$$= {\cdot}35 + \frac{9 + {\cdot}042}{2} = {\cdot}54\text{in.}$$

The total length of wire will be

$$= \frac{{\cdot}54 \times 44 \times 1{,}222}{7}$$
$$= 4{,}148\text{in.}$$

The resistance of the solenoid then will be

$$4{,}148 \times {\cdot}0007786$$
$$= 3{\cdot}2 \text{ ohms.}$$

Now, I should advise "Solenoid" to use two four-volt accumulators in series. When fully charged the voltage will be about 4·2 each, or 8·4 the two, and the internal resistance may be about ·2 ohm each. On a discharge of about two amperes the voltage will fall to eight volts. The current obtained then will be

$$\frac{8}{3{\cdot}2 + {\cdot}4} = \frac{8}{3{\cdot}6} = 2\,2 \text{ amperes.}$$

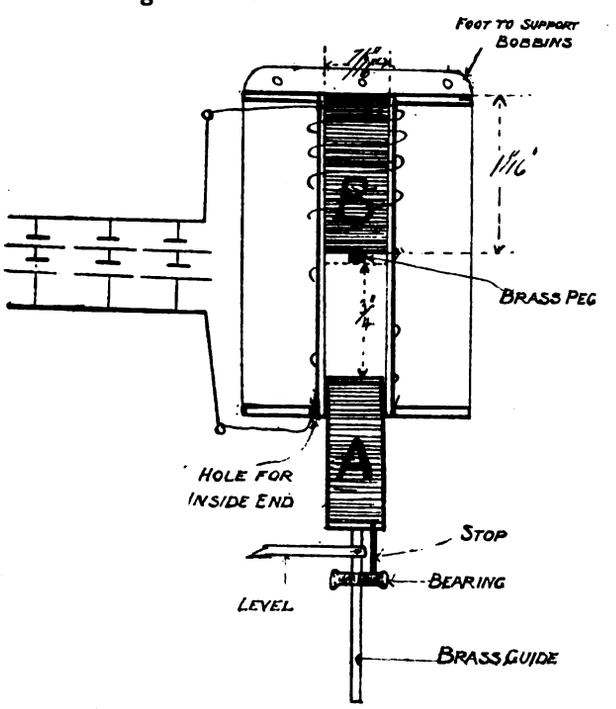
It will be impossible to use Leclanché cells because they have a high internal resistance, and even a large number of them would not give a current large enough for our purpose under the above conditions. I think that if it be possible to increase the length of the lever as above, the solenoid I have designed will give the requisite pull.—ERNEST P. HOLLIS.

Answer to No. 815 (*awarded 7s. 6d.*).—It is quite possible to make a solenoid to work from a few cells and be capable of doing all that is specified in the question. If the solenoid is to be used only occasionally, and for not more than an hour at a stretch, a battery of about six Daniell cells would be sufficient. If the solenoid is to be used frequently, and is likely to be used for more than an hour at a stretch, it will be found much more convenient and economical to use three two-volt 10-20 ampere-hour accumulators instead of the Daniell cells.

From my experience of solenoids, I should think the following arrangement would be the best under the circumstances. The smallest size which the coil can be conveniently made is 2in. long by 1½in. diameter. The

Digitized by Google

plunger (A in sketch) should be of wrought iron and about $\frac{3}{8}$in. diameter, therefore in order to allow a fair clearance the inside diameter of solenoid must be about $\frac{7}{16}$in.; the plunger should be about 1in. long. This leaves $\frac{1}{4}$in. of it in the solenoid when the plunger is in the "off" position. A piece of wrought iron (B in the sketch) is permanently fixed as shown by making it an easy driving fit into the inside of the solenoid. When the current is switched on this becomes a magnet, and as such assists the solenoid in lifting A. This arrangement, which is equivalent to increasing the ampere-turns, enables a smaller coil to be used than would otherwise be possible. The winding space available on the bobbin is 2in. by ·5in., and since from sketch the mean diameter of the winding is 1in., the mean length of one turn is 3·2in. (approximate). The ampere-turns required to give the pull of 1½lb. will be about 2,000 with the arrangement shown.



The voltage and the arrangement of the cells must now be considered. If six Daniell cells are used, they will be best connected up as shown in the sketch—that is, connected up two in series, and the three sets of two all in parallel. This gives roughly two volts. If three two-volt accumulators are used, they can be all connected in parallel. With either of these two sources of current it will be possible to get five amperes without overworking the cells, provided that the source is chosen in accordance with the advice given above.

Having decided on using two volts and five amperes, the maximum allowable resistance of the winding is $=\frac{2}{5}=$·4 ohm. Also, since 2,000 ampere-turns are required,

$$\text{turns}=\frac{2{,}000}{5}=400 \text{ turns.}$$

These 400 turns must be got into the space of 2in. × ·5in., or one square inch. ∴ (assuming no "bedding")

$$\text{diameter of one turn}=\frac{1\cdot0}{400}=\cdot0025 \text{ square inch.}$$

From this area the diameter is found:

$$\text{Area}=\cdot785\,d^2. \quad \therefore \text{ diameter } (d)=\sqrt{\frac{a}{\cdot785}}=\frac{\cdot0025}{\cdot785}=\cdot057\text{in.}$$

Allowing for insulation, the diameter of the wire will be about ·052in. The total length of wire is 3·2in. × 400 = 1,280in. = 36 yards (approximate); ∴ resistance per yard of wire must be ·012 ohm. Also the wire must carry five amperes without heating up unduly.

The wire which most closely meets the above requirements as regards diameter, resistance per yard, and carrying capacity is found from wire tables to be 17 S.W.G. This is the wire which must be used to wind the coil. About 1¼lb. of wire will be required.

The bobbin on which the coil is to be wound may be easily made by obtaining a piece of brass tube $\frac{7}{16}$in. inside diameter and long enough to take 2in. of winding and allow of a flange, cut out of thin sheet brass, being soldered on to each end. The inside of the bobbin must be perfectly smooth. As the voltage is so very low, the bobbin need not be insulated, but can have the wire wound on directly. The wire, which should be either single cotton or silk covered, must be carefully examined, as it is being wound on, to see that there are no bare places. If there are any, a small piece of silk ribbon should be wrapt round the bare wire, to insulate it. As both ends of the wire are wanted to be free, it will be necessary to drill a small hole in one of the flanges in the position shown, and through this the commencing end must be passed. When all the wire has been wound on as tightly as possible, and the bobbin is full, it must be well tied down to prevent its coming unwound. This can best be done by wrapping some insulating tape round the coil, and then finishing off with a layer of string tightly tied. The solenoid can then be mounted on a board, and connected up.—H. A. C.

Question No. 816.—Why should a Lancashire boiler give a dull boom at intervals of, say, half an hour, or less, which can be heard 30 yards away, and make the steam blow off suddenly at the safety valve when the blow-off cock happens to be leaking? The blow-off cock is of the Hopkinson type. The blow-off cock delivers below the surface to a stream of water. Also, would the above effect be likely to be at all detrimental to its safety?

Answer to No. 816 (*awarded* 10*s.*).—The dull boom is evidently one of the effects of "water-hammer" caused by the sudden condensation of steam *in* the blow-off pipe and *around* that end of it which discharges below the surface of the stream. The reason why the steam blows off suddenly at the safety valve is that the blow-off pipe transmits the shock caused by "water-hammer" to the boiler, and this acts in the following manner: In the ordinary course of generating steam the inner surface of the boiler below water-level is covered with myriads of small bubbles of steam, which, as they grow larger, rise uniformly to the surface and thus keep up the steam pressure. The shock or sudden vibration has the effect of instantaneously detaching thousands of bubbles of steam, which but for the shock would have clung a little longer to the metal surface. These bubbles, in addition to those rising normally, produce a more furious boiling and a more copious generation of steam. This increases the pressure and lifts the safety valve. There will also be the danger of "priming." The effect of shock in detaching steam bubbles from surfaces below water-level may be observed by striking any small vessel, such as a saucepan, containing water kept almost at boiling point.

Now for the cause of the intervals of 30 minutes or less. The blow-off pipe is either higher than the water-level of the stream and has a downward bend at the end to discharge under water, or the blow-off pipe is below the water-level of the stream, and is simply carried through the side of the stream, thus entering the water. In either case the pipe will in ordinary working be always full of water, for in the case where it is higher than the water-level, on opening and then closing the cock a vacuum will be formed in the pipe, and the water from the stream will rush up and fill it.

Now, suppose the blow-off cock is leaking sufficiently to produce the results stated in the question, at first the water leaking through the cock will be cooled by the water in the pipe, but gradually the water and the pipe will get warmer, and their temperature will eventually rise to atmospheric boiling point. The water which now leaks through the cock, coming from a condition where the boiling point is high to the lower boiling point of the atmosphere, passes at once into steam; this drives back the water in the pipe and fills the pipe with steam. Further leakage increases the steam pressure in the pipe, and eventually the pressure rises sufficiently for the steam to drive back the head of water (due to discharging under the surface). The steam now rushes out into the stream, only to be immediately condensed. As the leak is not great enough to keep up the steam pressure, the water from the stream rushes up the pipe, condensing the remaining steam, and gaining energy as it travels until it strikes the plug of the blow-off valve or any

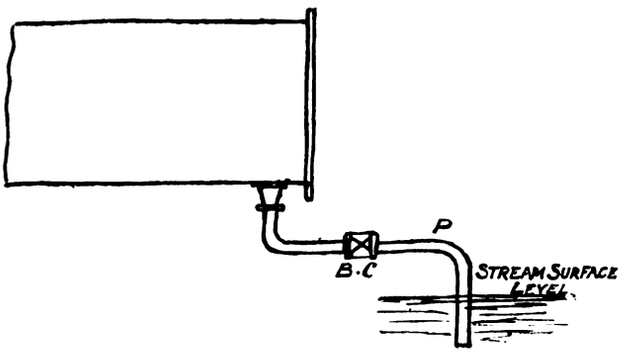
Digitized by Google

bends in the pipe. This produces the shock. The dull boom is heard so far away by reason of some of the sound being generated in the water of the stream by condensation of the steam issuing from the pipe. All shock is bad for boilers, and ought to be stopped.

If it be imperative to sometimes discharge under water, then a branch pipe ought to be taken from the existing pipe near to the blow-off cock and be led so as to discharge into the stream *above* the water-level. Two additional valves will be required, one in the branch pipe and one in the original pipe, placed beyond the branch, so that the discharge may be directed through either of them.

Some boiler explosions appear to be due to an instantaneous increase in the generation of steam, the nature of which is unknown, and such cases as the one in question ought to be promptly dealt with.—F. P. S.

Answer to No. 816 (*awarded* 7*s.* 6*d*).—The figure represents the probable arrangement of the blow-off from the boiler. The end of the pipe, P, being under water, a seal is thereby effected, and gradually the pipe is filled with water, partly by steam condensed after passing the cock, partly by water escaping through, and partly by water which creeps up to fill the vacuum caused by the condensation. So that, at a certain instant, the pipe, P, is full of water right up to the blow-off cock, B C. Now, the action of blowing off, whether by leakage or by the normal opening of the valve, creates in a less or greater degree a vacuum in the blow-off cock and connector, so that if the leakage be at all intermittent—as most probably it is—there will be an instant when (the pipe, P, being full) water is sucked back into the connection to the boiler.



This is possible at the instant P is full on account of the inertia, as it were, of the column of water, and before the pipe is cleared by the pressure. The water entering the vacuum is instantaneously vaporised, and the resultant comparatively large volume of steam, encased, so to speak, in an envelope of water, causes a disruptive increase of pressure. Hence the boom and the blowing off at the safety valve. The pipe, P, is cleared at the same time and the operation repeats itself. The effect on the boiler cannot but be detrimental; any sudden increases of pressure tend to strain the shell, and as the blow-off cock leak will naturally increase, the effect will be multiplied. The introduction of disruptive strains of this type will certainly not conduce to safety, even though they may not be absolutely dangerous. The remedy, of course, is to cut the pipe, P, so that it has a free delivery outside the stream.—S. E. T.

Answer to No. 816 (*awarded* 7*s.* 6*d.*).—The cause of this effect is the leaking of the blow-off cock, which allows hot water to accumulate in the delivery pipe. No doubt this pipe is laid so that it drains towards the stream in which its end is immersed, and the hot water being lighter than the cold water of the stream accumulates for a short distance only up the pipe, while hot or perhaps boiling water flows down the pipe in a continuous stream, which warms the pipe and at the same time fills it with vapour or perhaps steam. This condition cannot remain in equilibrium for long, because the heat and vapour are accumulating steadily in the pipe, and so the water at its lower extremity is blown out, but the pressure being thus relieved and the warm water driven out into the stream, cold water enters the pipe, and, of course, rapidly condenses the vapour as it comes in contact with it, and is consequently drawn up the vacuous pipe with considerable rapidity and force to strike the blow-off cock, which communicates the blow to the boiler and so gives a sudden jerk to the safety valve, and lets a little steam blow out there. The cold water now sinks back again by its own weight to a point of equilibrium and the process is repeated, but, the pipe being cold and large and the leak of hot water being small, some time is required to fill the pipe with vapour again for the necessary pressure for a fresh start. I consider that this action would be distinctly detrimental to the boiler, because the blow from the water is hard and powerful, and will probably in time injure the boiler plate holding the blow-off cock. In addition to its force, the blow thus given is frequent, and, therefore, it is almost certain to be doing some more or less subtle injury to the boiler. It is the sort of action which would crack a plate, break a rivet, or make a leak, and I do not believe that the Boiler Insurance Company would allow it to continue, especially as the remedy is so simple and inexpensive.

There are two easy and satisfactory remedies. First, remove the lower end of the pipe from the stream or brook so that it is open to the air—this is the best; secondly, repair the blow-off cock so that it does not leak, and if the outlet of the pipe cannot be taken out of the stream or brook, bore a $\frac{1}{4}$in. hole in it to let air in, but be careful in this case that the hot water and steam at blowing-off times do not get through it and do any damage.—F. G. A.

Answer to No. 816 (*awarded* 5*s*).—The following is probably the cause of the "boom." The outlet of the discharge pipe is below the surface of a stream, so that in its normal condition it is full of cold water right up to the blow-down cock. When the blow-down cock leaks, the cold water in the pipe is gradually displaced by the incoming hot water, which, if the pipe has a drop towards the stream (which is probable), will tend to collect at the boiler end by virtue of its lighter density; as the water leaks through, the temperature will increase until it is at boiling point, when, as the water is completely void of absorbed air, there will be a sudden generation of steam that will blow the pipe out clear, causing the rumble noted. When the pressure in the pipe is reduced sufficiently, the remaining steam will condense and the cold water will rush back into the pipe, whence the operations are repeated. If it is a deadweight safety valve, the sudden shock on the boiler would cause the valve seatings to jar, so allowing steam to escape. There is a danger of the continued shocks disturbing the boiler on its settings, and causing the joints on the boiler to blown-down cock to leak. If the discharge has a turned-down bend in the water the disturbance would be aggravated.—J. A. V. AND G. A. T.

Question No. 817.—A car weighing 10 tons when loaded gets out of control down an incline of 1·5 in 100, and moves at the rate of 20 miles an hour, and on the application of the emergency brake it is pulled up in a distance of 20 yards. What is the energy dissipated, the average brake power, the retardation, and the time taken in pulling up

Answer to No. 817 (*awarded* 7*s.* 6*d.*).—In this question no mention is made of friction or windage losses which would have a retarding effect on the car. The 1·5 per cent. grade would have the effect of adding to the kinetic energy energy of the car. In Fig. 1, if the length of the inclined

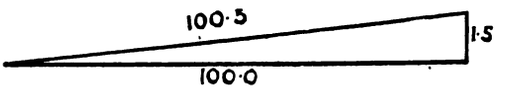


Fig. 1.

track = 100·5, this corresponds to a horizontal length of 100·0, the third side of the triangle corresponding to the per cent. grade. The kinetic energy of the car should for extreme accuracy be calculated in two parts: (1) the kinetic energy stored in it due to its motion along a horizontal plane proportional to the side 100·0; and (2) the kinetic energy stored in it due to its falling, under the influence of gravity, through a vertical distance proportional to the side 1·5. This second part has been taken to be cancelled by the retarding effect due to friction and windage losses.

The kinetic energy of the car in moving along horizontally

Digitized by Google

$= \frac{1}{2} m v^2$, where m = weight in lbs./32, and v = velocity in feet per second.

$$\therefore \text{ K.E.} = \frac{1}{2} \times \frac{10 \times 2{,}240}{32} \times (29{\cdot}35)^2$$

$$= 301{,}800 \text{ foot-pounds.}$$

This equals the *energy dissipated* during the pulling up of the car by braking. Further, force = mass × acceleration, or $f = m\,a$. Also, work or energy = force × distance, or $W = f\,s$.

$$\therefore W = m\,a\,s \qquad (s = 60\text{ft.}).$$

$$W = 301{,}800 = m\ a\ s = \frac{10 \times 2.240}{32} \times a \times 60.$$

$$\therefore a = 7{\cdot}18 \text{ feet per second per second.}$$

This equals the *retardation*. Now, the velocity of a body, v, at the end of a time t, the initial velocity being V, and the acceleration being a, is $v = V + a\ t$. In this case the brakes cause a negative acceleration—*i.e.*, a retardation,

$$\therefore v = V - a\ t.$$

Now at the end of the journey, the car being at rest, $v = 0$; also V = 29·35ft. per minute, and a, as already found, = 7·18.

$$\therefore 0 = 29{\cdot}35 - 7{\cdot}19\ t. \quad \therefore t = 4{\cdot}09 \text{ seconds.}$$

This is the *time taken in pulling up*. We can now find the average brake power. Thus

$$f = m\ a = \frac{10 \times 2{,}240}{32} \times 7{\cdot}18.$$

$$\therefore f = 5{,}030\text{lb.}$$

That this is so can be seen by multiplying this average brake power by the distance travelled, and the result should be the energy dissipated in braking. Thus

$$5{,}030 \times 60 = 301{,}800 \text{ foot-pounds.}$$

It is interesting to see how the kinetic energy of the car is destroyed by braking and the car finally brought to a standstill. This is set forth in Table A. The results are only of slide-rule accuracy, and are calculated to the end of the fourth second, at which point it will be seen that the velocity of the car is reduced to 0·58ft. per second.

TABLE A.

Time.	Kinetic energy.	Velocity.	Mean velocity during the second.	Kinetic energy lost during the second.
0	301,800	29·3		
End of first second ...	172,500	22·12	4·17	21,000
End of second second	79,200	14·94	11·35	57,000
End of third second...	22,200	7·76	18·53	93 300
End of fourth second	1,200	0·58	25·71	129,300

—S. S. L.

Answer to No. 817 (*awarded* 7*s.* 6*d.*).—(*a*) The energy dissipated is evidently the difference between the energy stored in the car on putting on the brake and the energy stored in the car when it is brought to rest, which is zero—that is, the energy dissipated is simply the kinetic energy due to a mass of 10 tons moving at 20 miles an hour, or $\frac{88}{3}$ft. per second, since 15 miles an hour is the same as 22ft. per second. This is, in foot-poundals,

$$\frac{1}{2} \times 10 \times 2{,}240 \times \frac{88}{3} \times \frac{88}{3},$$

which, taking g (the acceleration due to gravity of a freely falling body) as being 32·2, is equal to

$$\frac{1}{2} \times 10 \times 2{,}240 \times \frac{88}{3} \times \frac{88}{3} \times \frac{1}{32{\cdot}2} \text{ foot-pounds,}$$

i.e., to 299,200 foot-pounds.

(*b*) The retardation can be got from the usual formula connecting initial and final velocity with acceleration and space passed over. It is assumed that the retardation is constant, which might not be quite correct under some circumstances. If the brake acts electrically by friction on the rails, then as the car slows down the pressure will alter, and, consequently, the retardation will diminish as rest is approached; the same will apply if the wheels are locked by pressure applied electromagnetically, and the braking takes place by friction between rails and wheels, the latter not revolving. Assuming, however, that retardation is constant, we have

(Final velocity)² = (initial velocity)² + (2 × acceleration × space passed over)

or, $$0 = \frac{88}{3} \times \frac{88}{3} + 2 \times a \times 3 \times 20$$

or, $$A = -\frac{88 \times 88}{1{,}080} = -7{\cdot}17\text{ft. per second per second,}$$

the negative sign showing that the acceleration acts against the car's motion retarding it.

(*c*) The time taken in pulling up is got from the formula connecting space passed over with initial velocity, acceleration, and time during which the acceleration acts.

Space passed over = initial velocity × time + ½ acceleration × (time)²

or, $$60 = \frac{88}{3} \times t - \frac{1}{2} \times \frac{968}{135}\ t^2$$

or, $$15 = \frac{22}{3}\ t - \frac{121}{135}\ t^2$$

or, $$121\ t^2 - 990\ t + 2{,}025 = 0$$

or, $$(11\ t - 45)^2 = 0,$$

which shows that the car pulls up in $\frac{45}{11}$ or $4\frac{1}{11}$ seconds.

(*d*) It is not very clear what is meant by "average brake power." If it is to be taken as the average horse-power due to the action of the brake in pulling up, we must find the retarding force exerted by the brake. The net retarding force is got from the knowledge of the mass acted upon and the negative acceleration, or retardation, produced by the retarding force.

Retarding force (poundals)

$$= -10 \times 2{,}240 \times \frac{968}{135}.$$

This is the resultant of all the forces acting on the car—that is, it is the difference between the retarding force applied by the brakes and the accelerating force due to the car being on an inclined plane. This accelerating force, according to the triangle of forces proper to the particular plane under consideration, is $\frac{1{\cdot}5}{100} \times 10 \times 2{,}240 \times 32{\cdot}2$ poundals. Hence the retarding force exerted by the brakes is

$$\left(\frac{1{\cdot}5}{100} \times 10 \times 2{,}240 \times 32{\cdot}2\right) + \left(\frac{968}{135} \times 10 \times 2{,}240\right) \text{ poundals,}$$

which, worked out, gives

$$\left\{\left(\frac{1{\cdot}5}{100} \times 32{\cdot}2\right) + \left(\frac{968}{135}\right)\right\} 10 \times 2{,}240 \text{ poundals,}$$

or, $$\left\{\frac{1{\cdot}5}{100} + \frac{968}{135 \times 32{\cdot}2}\right\} \times 10 \times 2{,}240\text{lb., or } 5{,}321\text{lb.}$$

This acts for $\frac{45}{11}$ seconds, so that the horse-power during the retarding is given by

$$5{,}321 \times 60 \times \frac{11}{45} \times \frac{1}{33{,}000} \times 60$$

or, $$141{\cdot}9 \text{ h.p.}$$

This answers (*d*) whether horse-power or only actual backward pull is intended. It should be noted that if the wheels are revolving during the braking, there is, in addition to the braking retardation, that due to the friction of wheels and motors in their bearings, this force being equal to the total mass of the cars, multiplied by 32·2 times the coefficient of friction effective for the rolling between the car and the rails: this force would thus be given in poundals, and would, of course, need to be subtracted from the force previously found to be due to the brakes, as it acts in the same direction as the net retarding force. As, however, the coefficient of rolling friction is not given, this quantity is indefinite, and the result given is obviously a maximum possible value.—T. C.

ANSWERS.

Question No. 817.—A car weighing 10 tons when loaded gets out of control down an incline of 1·5 in 100, and moves at the rate of 20 miles an hour, and on the application of the emergency brake it is pulled up in a distance of 20 yards. What is the energy dissipated, the average brake power, the retardation, and the time taken in pulling up

Answer to No. 817 (*awarded* 5*s.*).—The total energy dissipated by the car during the process of pulling up consists of two parts. In the first place, the car, owing to its velocity, will have a certain kinetic energy; and in the second place, since the car drops through a certain distance during the time in which it is being stopped, it will also have (at the instant when the brakes are applied) a certain amount of energy due to its position, or, as it is termed, potential energy. The sum of the above two quantities of energy represents the amount which has to be dissipated before the car is brought to rest.

Now, the kinetic energy of a moving body is equal to $\frac{1}{2}\frac{M V^2}{32\cdot2}$ foot-pounds, M and V being the mass in pounds and velocity in feet per second respectively.

$\therefore$ K. E. of car $= \frac{2,240 \times 10 \times (29\cdot33)^2}{2 \times 32\cdot2} = 299,100$ ft.-lbs.

Again, while the car is moving through a distance of 20 yards along the road it will fall vertically through $60 \times \cdot015 = \cdot9$ft.

$\therefore$ potential energy given to car $= 10 \times 2,240 \times \cdot9 = 20,160$ foot-pounds.

$\therefore$ total energy to be dissipated during braking operation $= 299,100 + 20,160 = 319,260$ foot-pounds.

Now, in order to get the retardation and the time occupied in stopping the car, it will be necessary to know the law according to which the brakes act. For instance, whether the retardation is, or is not, uniform. Let us consider it to be uniform; then it will be evident that the average velocity during the period of braking will be 10 miles per hour, or 14·67ft. per second, and the time occupied in pulling up will be $\frac{60}{14\cdot67} = 4\cdot09$ seconds. The retardation being the decrease in velocity per second is evidently

$$\frac{29\cdot33}{4\cdot09} = 7\cdot17\text{ft. per second per second.}$$

The term average brake power is a little indefinite, but assuming it to mean the average power dissipated during braking, we have

$$\text{average horse-power} = \frac{319.260}{4\cdot09 \times 550} = 142\cdot2.$$

It may be noted that a small portion of this power will be due to the ordinary friction losses of the wheels and gearing, the remaining portion being due to the application of the emergency brake.—β^2.

Answer to No. 817 (*awarded* 5*s.*).—This question is only a matter of applied mechanics, and the first thing to find before it can be answered is the velocity of the car in feet per second. As the speed is given, no notice need be taken of the incline.

The velocity in feet per second $= \frac{20 \times 1.760 \times 3}{60 \times 60} = 29\frac{1}{3}$.

1. Having found this, the energy of the car due to its motion down can now be calculated. This is the kinetic energy, and is the dissipated or wasted energy, as it is not used in any way. The kinetic energy $= \frac{W v^2}{2 g}$, where W = weight car in pounds, v^2 = (velocity)^2, and $g = 32\cdot2$.

$\therefore$ K.E. $= \frac{10 \times 2,240 \times 29\frac{1}{3} \times 29\frac{1}{3}}{2 \times 32\cdot2} = 299,464\cdot1$ foot-pounds.

2. The car contains 299,464·1 foot-pounds of energy which have to be destroyed before it is brought to rest. In the question it is stated that the car was brought to rest in a distance of 20 yards = 60ft.

$\therefore$ average brake-power $= \frac{299,464\cdot1}{60} = 4,991\cdot6$lb.

3. When the brakes are applied to the car, its acceleration is gradually decreased to zero until the car stops. This negative or decreasing acceleration is called the retardation. To calculate it, take the formula $P = \frac{W a}{g}$, where P = braking power in pounds, W = weight of car in pounds, $g = 32\cdot2$, and a is the acceleration or retardation in feet per second per second.

If $P = \frac{W a}{g}$, then $a = \frac{P g}{W} = \frac{4,991\cdot6 \times 32\cdot2}{10 \times 2,240}$

$= 7\cdot17$ feet per second per second.

4. To find the time taken in pulling up take the same formula, $P = \frac{W a}{g}$. This must be modified by putting

$$a = \frac{\text{velocity}}{\text{time seconds}} = \frac{v}{t}.$$

Again, if $P = \frac{W v}{g t}$, then $t = \frac{W v}{g P}$

$$= \frac{10 = 2,240 \times 29\frac{1}{3}}{32\cdot2 \times 4,991\cdot6}$$

$= 4\cdot1$ seconds.

The time taken to pull up and the retardation may be found in two ways, both of which will give the same results.

Take the formula for a falling body or a body moving freely down an incline under the force of gravity. The formula is $h = \frac{v}{2} t$, where h = height of fall, or in this case the distance travelled by the car in feet. v = velocity feet per second, t = time in seconds.

$h = \frac{v t}{2}$. $\therefore t = \frac{2 h}{v} = \frac{2 \times 20}{29\frac{1}{3}} = 4\cdot09$ seconds.

Retardation.—This time the formula $a = \frac{v}{t}$ will answer our purpose nicely. This has just been stated.

$\therefore a = \frac{29\frac{1}{3}}{4\cdot09} = 7\cdot155$ft. per second per second.

—H. H. H.

Answer to No. 817 (*awarded* 5*s.*).—The whole energy dissipated is that due to (1) the velocity of the car, and (2) gravitation acting on the car while it moves down the incline from the time when the brakes are applied. Since the velocity is reduced from 20 miles per hour to zero, the velocity destroyed is, of course, 20 miles per hour.

Now, 60 miles per hour = 88ft. per second;

$\therefore$ 20 miles per hour $= \frac{88 \times 20}{60} = \frac{88}{3}$ feet per second.

Energy dissipated due to (1) in foot-pounds

$= \frac{1}{2} \frac{\text{weight in pounds}}{g} \times \text{square of velocity in feet per second}$

$= \frac{1}{2} \frac{10 \times 2.240}{32\cdot2} \times \left(\frac{88}{3}\right)^2 = 299,300$ foot-pounds.

Now, the slope is 1·5 in 100; hence, as the car moves 20 yards (= 60ft.) along the rails, it moves a distance in the direction of gravity

$$= \frac{1\cdot5}{100} \times 60 = \cdot9\text{ft.}$$

(Since the slope is small, it does not matter whether we measure the 20 yards along the rails or along the horizontal.) Hence work done due to (2) in foot-pounds = distance in feet through which the car moves in the direction of gravity × weight of car in pounds,

$= \cdot9 \times 10 \times 2,240 = 20,160$ foot-pounds.

$\therefore$ whole energy dissipated = 299,300 + 20,106 = 319,500 (say)

Average Brake Power.—The force exerted by the brake has to do 319,500 foot-pounds of work in 20 yards (60ft.).

Digitized by Google

Let F = force in pounds,

$$\therefore F \times 60 = 319{,}500 \text{ foot-pounds}$$

$$\therefore F = \frac{319{,}500}{60} = 5{,}325\text{lb.}$$

Time in Pulling Up.—Assuming the retardation constant, the time average of the speed $= \frac{20}{2} = 10$ miles per hour, or $10 \times \frac{88}{60}$ feet per second.

Time taken in seconds

$$= \frac{\text{space described in feet}}{\text{speed in feet per second}}$$

$$= \frac{60}{\frac{88 \times 10}{60}} = 4\tfrac{1}{11} \text{ seconds.}$$

Retardation.—The retardation in feet per second per second

$$= \frac{\text{speed destroyed in feet per second}}{\text{time of destroying the speed in seconds}}$$

$$= \frac{88}{3} \div \frac{45}{11} = 7{\cdot}17 \text{ feet per second per second.}$$

—H. R.

Question No. 818.—I am anxious to study the wave forms in various parts of an alternating-current circuit. Can anyone describe the construction of a simple form of "oscillograph"?

Answer to No. 818 (*awarded* 10*s.*).—A simple form of oscillograph was described by A. Wehnelt in a paper before the German Physical Society some two years ago, and which is described in the *Electrical Engineer* of Oct. 9, 1903. The principle of the instrument is the same as that of the well-known Duddell oscillograph, and the author states that

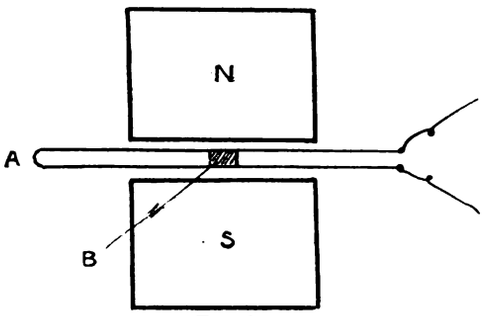

FIG. 1.

in the case of comparatively slow periodic charges, such as alternating currents at ordinary frequencies, it has proved quite successful. Fig. 1 shows a diagrammatic representation of the instrument. It consists essentially of a loop, A, of hard-drawn silver wire, tightly stretched between the poles, N and S, of an electromagnet. A small mirror, B, is stuck across the loop and lies midway between the poles. The sides of the loop, which should be parallel, are from 2mm. to 3mm. apart, and the gap between the poles should be just sufficient to allow free movement of the loop. When a current is sent through the wire with the magnets excited, the loop is deflected about its longitudinal axis by an amount approximately proportional to the current. If the current varies periodically, the instantaneous deflections will still be proportional to the instantaneous current values, provided that the natural period of the moving system is very small compared with the period of the current, and also that the damping of the system is great. By employing a powerful magnet and a tightly-stretched wire both these conditions may be fulfilled. Consequently, when an alternating current passes round the loop, the moving system is set into a state of rapid vibration exactly coincident with the alternations of the current.

Fig. 2 is a photograph of the apparatus as constructed by the author of the aforementioned paper. Two identical oscillographs are supported one above the other in an easily adjustable manner. The poles of the electromagnet are in each case bevelled, and the loop which stretches between them is mounted on an ebonite strip with a milled headed screw at one end for adjusting the tension. Each oscillograph is mounted on a base, and the ends of the loop brought down to two terminals. By means of two oscillographs mounted in the manner shown, two curves can be taken simultaneously. Thus, if it is required to investigate the current and potential wave forms of an alternate-current circuit under various conditions, one oscillograph is connected in series with a high non-inductive resistance (dependent in value on the potential of the circuit) across

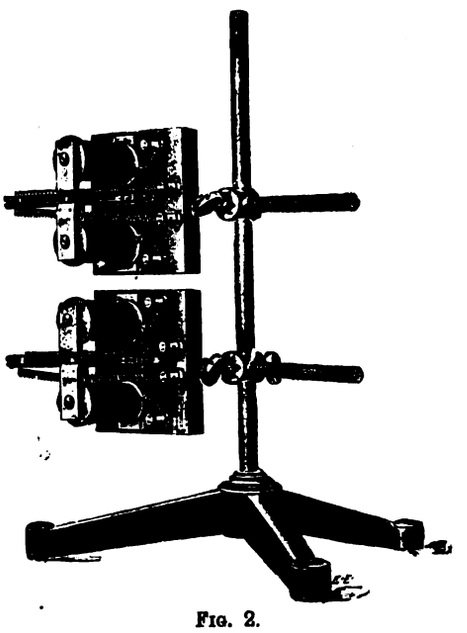

FIG. 2.

the circuit, and the other is connected across the ends of a small non-inductive resistance (dependent in value on the main current) connected in series with the load, so that it carries the main current. Obviously, the loop, A, being of very fine wire, the maximum current that it can carry will be very small, and in each case the current passing through it must be limited to this value.

The curves are exhibited on a screen by means of the arrangement shown diagrammatically in Fig. 3. A small 3½-ampere arc lamp, L, is used as a source of light and placed behind a lens, A, so that the rays which fall on the oscillograph mirrors are parallel. From these the light is reflected to a revolving mirror, Sp, and thence on to the screen, S. If the revolving mirror be at rest, two spots of light will appear on the screen, S, and by adjusting the position of either oscillograph these two spots should be made coincident. Everything is then ready for connecting the oscillographs in circuit in the manner previously indicated, and by rotating the mirror moderately fast the

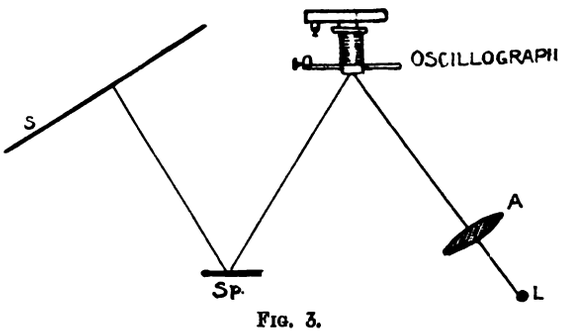

FIG. 3.

current and the potential waves will appear on the screen, S, developed along a vertical axis. It was found that if the periodic time of the changes to be considered was less than 0·1 second, the natural swing of the system will interfere with the results, as with such an instrument the natural time of swing is about ·003 second.

This instrument I think can be modified and much simplified in construction, and at the same time give satisfactory results, by combining the two oscillographs in one. To do this, two loops are placed between the poles of the electromagnet as indicated in Fig. 4, the loops being separated by a small piece of soft iron so that the field is practically uniform. To compensate for the increased air-gap, more ampere-turns would need to be put on the magnet core giving a field equally as strong as in the single instruments. Instead of using silver for the loops,

Digitized by Google

phosphor-bronze strip No. 0 size would do quite well, and it would safely carry $\frac{1}{10}$ ampere. By means of this combined instrument two wave-forms could be readily compared, and if it is desired to make photographic records the instrument could be placed in a box in which the lens, A, is permanently fixed, and an aperture provided in the side of the box through which the light from the source, L, can pass, first through the lens, A, and then on to the mirrors of the oscillograph. The rotating mirror, Sp, would in that case be replaced by a drum round which the film can be wrapped, and the reflected light from the oscillograph mirrors would have access to the film by means of an aperture which could be opened and closed from the

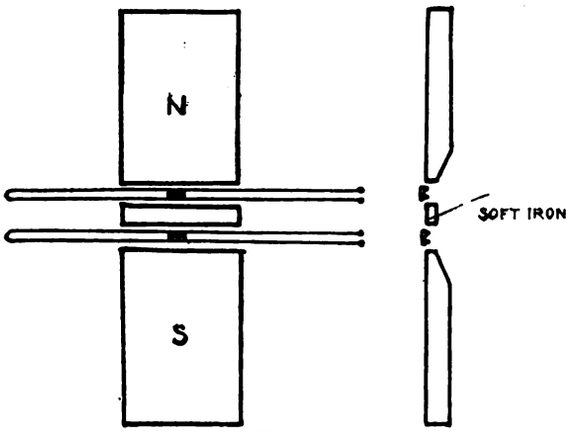

FIG. 4.

outside of the case. It is then only necessary to rotate the down at a uniform speed, which speed is dependent on the frequency of the alternations and the number of complete cycles that are desired to be recorded, and by opening the shutter for a period corresponding to one revolution of the drum you first obtain your zero line. Then connect the oscillograph in circuit and repeat. This will record the two waves, and the film can be developed in the ordinary way.—A. P. Y.

Answer to No. 818 (*awarded* 7*s.* 6*d.*).—The most perfect instrument for determination of wave-form at present available is the bifilar oscillograph as devised by Blondel and perfected by Duddell. Description of this is, however, here out of place, as it can scarcely be termed "simple," while its cost, complete, approximates to the inquirer's *nom de plume*. A simplified form has, nevertheless, been devised by Wehnelt, and of this a description appears in the *Electrical Engineer* of Oct. 9, 1903. As shown in Fig. 1 (this is the same as Fig. 2 of "A. P. Y.'s" answer—ED *E. E.*), upon a base board is mounted an electromagnet furnished with pole-pieces, the gap between which is a few centimetres long and about 4mm. across from pole to pole. For the purpose of concentrating the field in this gap, the pole edges are narrowed down to a few millimetres thickness. A loop of hard-drawn silver wire, tightly stretched on an ebonite bar, is adjusted in the polar gap, and carries a light mirror bridging across from wire to wire (Fig. 2). The two wires of the loop should

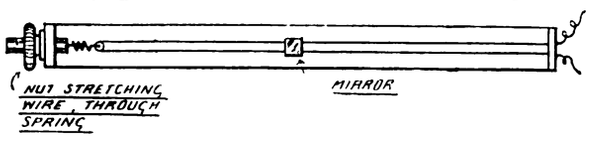

FIG. 2.

be from 2mm. to 3mm. apart, and it is advantageous to pass the looped end over a small pulley that their tension may be equalised. In use the current under investigation is passed through the loop, and the magnet is excited as strongly as possible. The further arrangements are as shown in Fig. 3. Rays issuing from a strong source of light, preferably an arc lamp or an optical lantern, are so focussed as to give an image on the screen after falling upon the oscillograph and rotating mirrors. If the latter be rotated synchronously with the alternations of current, so much the better, as a stationary image is obtained thereby.

This appliance may be purchased from Max Kohl, of Chemnitz, but is not, in all probability, beyond "Fifty-quida's" own constructive powers. Phosphor-bronze strip may be advantageously substituted for the silver wire, and this may be obtained at about 1*s.* a yard, while a suitable light and small mirror can be got by cutting down and silvering a microscope cover-glass. If the path of the light rays between the oscillograph and screen be a metre, an amplitude of 100cm. can be obtained on the screen, while the wire's natural period of vibration can be reduced to about ·003 second by due tension, and in this case fairly good results are given up to a current frequency of not greater than 100. Certain errors will be introduced with this simple instrument owing to the lack of damping, and these can only be avoided by enclosing the moving loop in some form of oil bath.

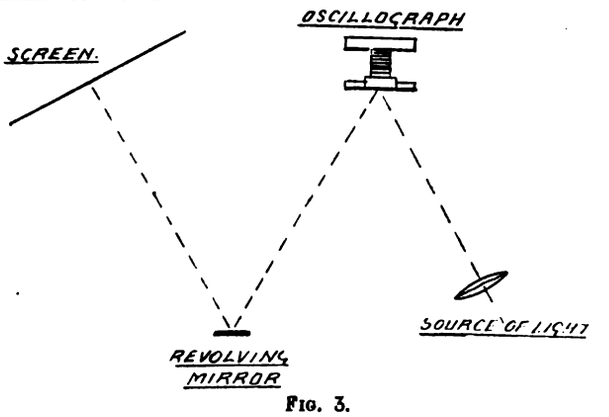

FIG. 3.

The Blondel soft-iron oscillograph is not extremely difficult to make, provided one can obtain the soft-iron band. In this instrument a soft-iron strip, about ·25mm. wide, ·05mm. thick, and a few centimetres long, is stretched between the poles of a powerful magnet. Coils carrying the current to be observed are disposed so as to give a field perpendicular to that of the magnet, and under the joint effect the iron band sets its breadth in the direction of the resultant field. The indications are obtained, as usual, by a tiny mirror attached by gum to the iron band. A complete description of this may be found in the *Revue Electrique* of April 12, 1902, and the essential disposition

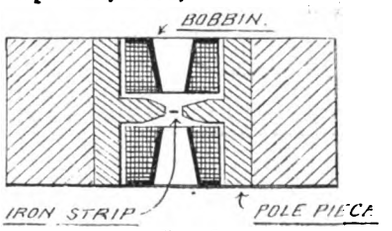

FIG. 4.

may be gathered from Fig. 4, which is a section across the gap.—ZERO.

Answer to No. 818 (*awarded* 5*s.*).—Owing to the extreme delicacy of the construction of an oscillograph, due to the rapid vibrations of the mirror, which demands as small a moment of inertia of the moving parts as possible, although the instrument is simple to understand, yet the writer is of the opinion that attempts to construct one by anyone who is not an expert will result in a disappointment. The piece of apparatus shown in Fig 1 will, he thinks, fulfil all requirements. The apparatus is for showing the shape of an E.M.F. curve. E D is an ebonite disc about 1ft. in diameter; T_1 and T_2 are connected to the terminals of the alternator; E V is an electrostatic voltmeter; B_1 and B_2 are two thin brushes, B_1 resting on the edge of ebonite disc, and B_2 on the brass collar, which is insulated from the shaft; S is a piece of brass let into the circumference of the ebonite disc, and is connected to the brass collar by the wire, W; *g* is the shaft of the alternator, and G S is a graduated scale by means of which the position of the brush B_1 can be noted. Now, as the alternator shaft rotates, the brush B_1 makes contact with S once in each revolution, and thus completes the circuit through the condenser. By the rapid succession of these very brief contacts, the condenser becomes charged to and is maintained at (provided there is no leakage) the same voltage

Digitized by Google

as the alternator terminals, or between T_1 and T_2, at the instant when contact is made. By altering the position of the brush we obtain the shape of the E M F. curve. If the readings on the electrostatic voltmeter are too small to be read accurately, they can be obtained by placing a certain number of cells—preferably secondary cells—in series with the voltmeter, and afterwards deducting the voltage of the cells from the voltmeter reading. It is necessary to use the condenser, as the leakage of an electrostatic voltmeter is too great; also the brush, B_1, must be thin, so that the time of contact is extremely small. If it is desired to calibrate the condenser and voltmeter, apply a known potential difference to the terminals, with B_1 making contact with S, and note the voltmeter reading. Then run the machine up to speed, and again note the reading. If any leakage occurs, we can, by comparing the two readings, obtain a constant to correct future readings.

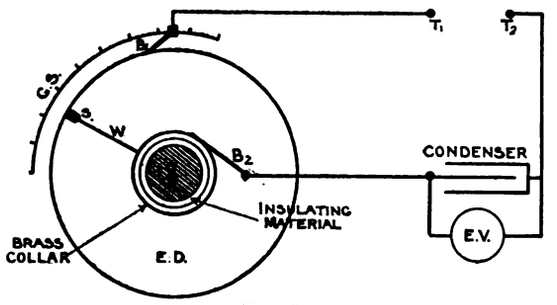

FIG. 1.

To obtain the shape of the current wave in an inductive circuit, the alterations as shown in Fig. 2 must be made, where R is a non-inductive resistance made as small as possible so that the working conditions of the circuit may not be affected, as it will be seen that R is in series with the inductive resistance of the external circuit, and that we are really measuring the potential difference between T_1 and T_2. Hence by Ohm's law we get $C = \frac{E}{R}$. G is a galvanometer, and T S is a two-way switch. A B is a wire along which passes a current supplied by a secondary cell. When working, the sliding contact, C, is adjusted until we get no deflection, when the potential difference at the condenser terminals will be proportional to the length

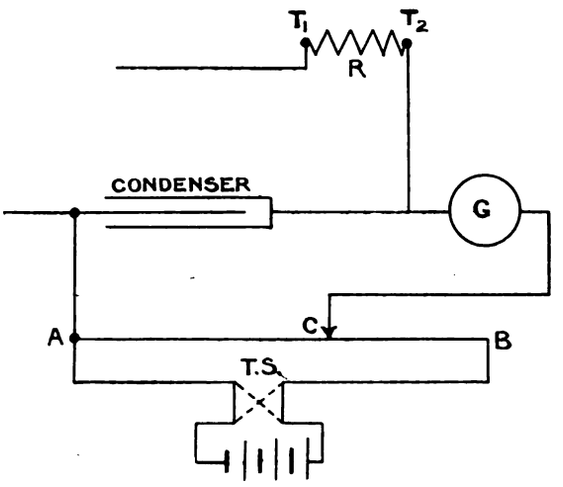

FIG. 2.

A C on the wire. To determine the constant to convert the scale reading of the sliding contact into amperes, a known current is passed through R, at the same time running the contact maker at the speed at which it is to be used, and the scale reading noted. If the alternator is not accessible, a synchronous motor driven from the alternator to be tested may be used for driving the instantaneous contact maker.—F. M. B.

Answer to No. 818 (*awarded* 5*s.*).—One of the simplest and cheapest forms of oscillographic wave tracers is that recently designed by Mr. R. Goldschmidt. Referring to Fig. 1, B and C are two solenoids which are energised by the alternating current of which it is desired to obtain the wave-form. A steel needle, A, is attracted and held by one of the magnets, and the other end being free the needle will oscillate, the amplitude of which depends on the wave form of the energising current. If the free end of the needle, A, is provided with a small mirror, a ray of light reflected from this mirror and projected to a screen will show a vertical line when the solenoids are energised. In order to obtain a movement of the needle representing the periodic time of the current, a further pair of solenoids, D and E, are provided, the axes of which are at right angles to the solenoids B and C (Fig. 2). The two pairs of solenoids are energised by the same current, and in parallel

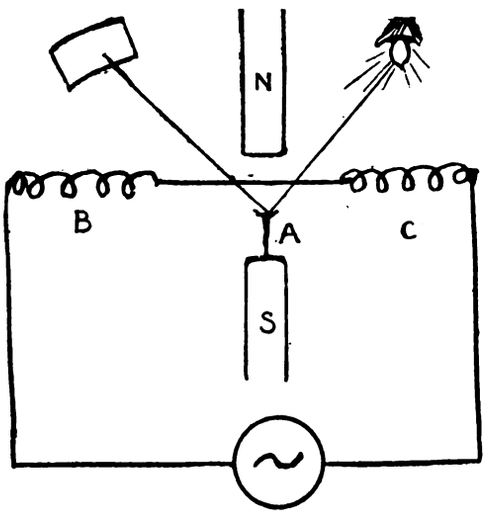

FIG. 1.

with one another. A non-inductive resistance, R, is placed in series with one pair, and a choking coil, I, is in series with the second pair. Now, if one pair of solenoids are energised the needle vibrates in a vertical or horizontal direction, as the case may be, but if the second pair is energised the needle vibrates in a vertical or horizontal direction, or at 90deg to the first movement. By energising both pairs at once a double movement of the needle is obtained. The use of the choking coil results in the current lagging about 90deg. in one pair of coils; therefore, one pair may be termed the voltage coil, and the

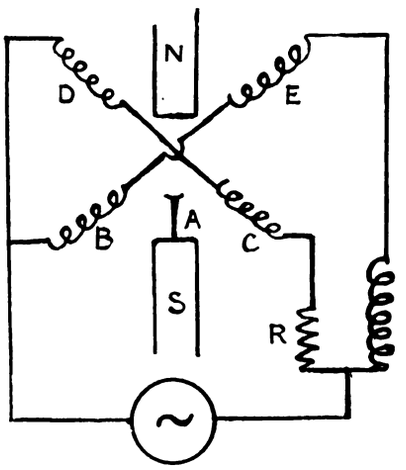

FIG. 2.

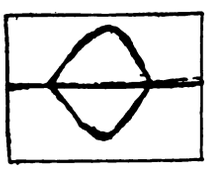

FIG. 3.

other the time coil. The resultant form of a sine curve projected on the screen will be as Fig. 3. The eddy currents induced in the solid pole by the needle vibrating prevents it showing a larger amplitude or periodic time than the actual current. In order to correct for any possible time error due to mirror, the light should be reflected on to a screen of semi circular form. It is, of course, necessary to obtain a current lag of 90deg. between the two pairs of coils, and this can easily be obtained by suitable connections of the choking coil or coils.—JUNO.

[Other replies to Question No. 818 will be given in our next issue.—ED. *E. E.*]

Supplement to "The Electrical Engineer,"
NOVEMBER 3, 1905.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

QUESTIONS.

825. Is it necessary to have a complete circuit in order to have a flow of electric current? I have noticed that you can have shocks to earth off either the positive or negative rails of a certain electric railway, *both* rails being insulated. Is this due to defective insulation, or is it due to the fact that there is a difference of potential between *either* rail and earth?—WATTMAN.

ANSWERS.

Question No. 818.—I am anxious to study the wave forms in various parts of an alternating-current circuit. Can anyone describe the construction of a simple form of "oscillograph"?

Answer to No. 818 (*awarded* 5*s.*).—The shape of the wave of an alternating current has a very important influence on the way in which the current will behave, and it is important to consider how that shape may be determined. The general frequency now used is about 50 periods per second, and in order to obtain an idea of the way in which the current is changing, the instrument will be required to move with great rapidity. An instrument known as the "Duddell oscillograph" is one which has this property, and can be used to draw the wave-forms with the greatest accuracy. Fig. 1 shows the instrument,

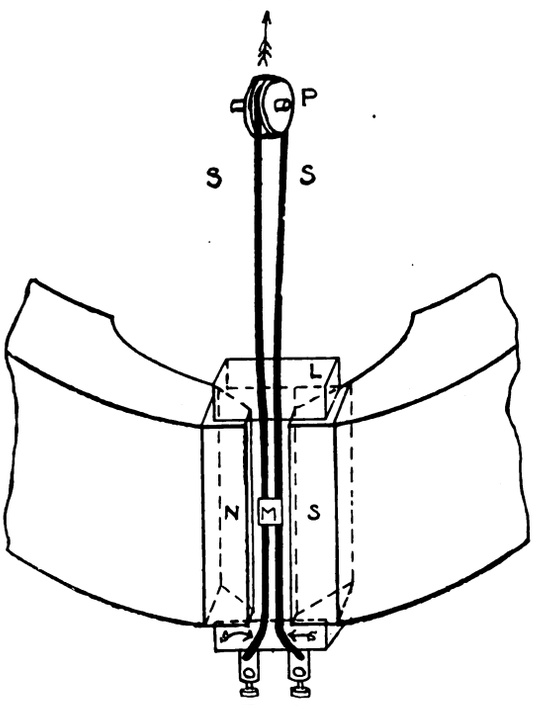

FIG. 1.

where S S are two strips of phosphor-bronze, which are stretched by means of a spring-balance applied to a pulley, P, between the poles of a powerful magnet, N S, and the circuit is arranged that the alternating current passes up one strip and down the other. When a current is sent through, both of the strips will be deflected, as it is well known that a conductor carrying a current, when placed in a magnetic field, tends to move in a direction perpendicular both to itself and to the direction of the field, but as the current flows up one strip and down the other the deflections will be in opposite directions, and in order to indicate the deflection of the strips a little mirror, M, is stuck on to them, so that when they are deflected the mirror will turn, the direction depending on the direction of current flowing in the strips. The moving parts of this instruments are made of such a size that they will be able to follow the rapidly changing forces that are made to act upon them, and therefore must move with great rapidity, or, in other words, their "free periodic time" must be very small. The strips, when deflected, will complete a back-and-forth movement in one three-thousandth of a second, and it is quite easy with this instrument to record accurately the wave-form of an alternating current with a frequency of 100 periods per second. It is not only essential that the moving parts and their free periodic time should be small, but they will require damping, otherwise the instrument will not record accurately.

In the Duddell oscillograph this damping is effected by enclosing the moving strips in a space filled with castor oil; this oil has great stickiness, and damps effectively the movement of the strips, so that the instrument will be deflected by its proper amount without any preliminary oscillations. When both of these conditions are fulfilled, the instrument will be deflected at any moment by an amount proportional to the actual value of the current flowing through it at that moment. When an alternating current is sent through the strips, all that is seen is a band of light reflected from the mirror on the screen, and in order to actually see the wave-form, some means must be devised of spreading the curve out; if the deflection be horizontal, the spot of light must be moved vertically, so that it is not in the same vertical position for every deflection. This is effected in a variety of ways, the simplest of which is by the use of a revolving mirror. The spot of light, when it has been deflected, is not viewed directly, but its reflection in a rapidly turning mirror is observed. In this case the motion of the spot is horizontal and the mirror is turned round a horizontal axis, so that an up or down vertical motion is given to the image of the spot as seen in the mirror.

Other methods of producing "time" motion have been employed, as has other oscillographs, and based on entirely different principles, but Duddell's is undoubtedly the best. The Blondel oscillograph is an instrument in which the moving part is a small soft-iron needle, which is deflected by a coil of wire carrying the alternating current. The fact that it depends for its working on a magnetic instead of an electromagnetic action necessarily entails a diminished accuracy for all waves that are not of a certain shape—a shape, however, to which in a great many cases a close approximation is made in practice.—J. P. S.

Question No. 819.—A three-phase plant generates current at 440 volts for power and transformed to 120 volts for lighting. The lighting circuit was originally wired for 240 volts continuous current. Could the transformers be dispensed with, and current taken from the mains and neutral point earthed, to obtain more light at about 250 volts? And taking, say, 100 amperes on each phase, what would be the current in the neutral wire?

Answer to No. 819 (*awarded* 10*s.*).—An almost complete answer to this question could be extracted from the information given in the article (on p. 492 of the issue in which it occurs) under the heading "Distribution by Three-Phase Currents." No doubt still more explanation will occur in the continuation of the article. But this answer will isolate the necessary information, and possibly allow it to be more easily followed than if it had to be sought for amongst other irrelevant matter. The wording of the question seems to indicate almost certainly that there is already a "neutral" point on the generating system—that is, that the generators are "star" connected. If this were not the case, it would be difficult, or impossible almost, to do what was wanted in any simple way. Reference to this will be made later. But assuming that there is a "star" connected generator, then the matter is comparatively easy.

In Fig. 1, let O, 1, 2, 3 be the generator, A B C and Z the three mains and neutral wires respectively, and O′ 1′, O′ 2′, and O′ 3′ the three lamp circuits as they would be connected up (one from each main to the neutral wire) after the transformers has been removed. The neutral wire, Z, is shown as a complete main from the lamps to the generator in the sketch, but it could be replaced as suggested, if desired, by an earth connection at the generator, and by a similar connection at each lamp or group of lamps as may be convenient. The power circuit is left out of the

Digitized by Google

above diagram for clearness, and it does not really enter the question, as its connections to mains corresponding to A B C would be unaltered by the new arrangement of lighting. It is evident from the sketch that lamps connected as above will be lit; the point remains as to what voltage will be got at the terminals of the lamps. In other words, if 440 volts is the "line" voltage in a star-connected generator, what will the "phase" voltage be, or, given the potential difference from 1 to 2 at 440 volts, find V_P, the difference of potential from O to 1 or O to 2.

Drawing the three voltages, O 1, O 2, O 3, in a vector diagram (see Fig. 2) we have to get the voltage due to the difference of potential, 1 2, which is equal to 440 volts. This difference of potential 1 2, is equal to the vector sum of the two voltages $+$O 1 and $-$O 2, and can be obtained graphically by compounding O1 with 4 1, which is equal in magnitude to O 2, but acts in the opposite direction to it.

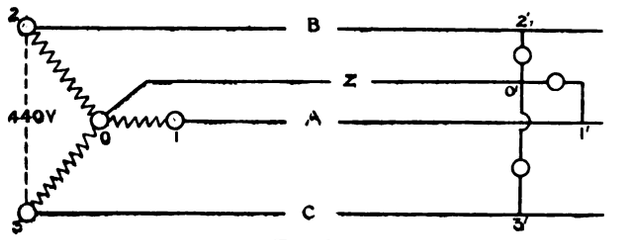

FIG. 1.

The resultant is 2 1 both in magnitude and direction, and this line bears to O 1 or O 2 (since these are 120deg. different in phase) the ratio of $\sqrt{3}$ to 1. Hence, if 2 1 represents 440 volts, the "phase" voltage is equal to $440 \div \sqrt{3}$, or 254 volts. That is to say, in the arrangement proposed the voltage available is 254 at the lamp terminals (assuming a negligible loss in the lines), which meets the case very very well. So far, then, it is all right, and 250-volt lamps can be coupled from mains to neutral point as desired. A little more light will be got than was originally possible at 240 volts owing to the higher pressure, and, provided the mains were fully loaded at the old continuous-current pressure, evidently it will be possible to get fully double the amount of light compared with what the mains were good for at 120 volts from the transformers.

As regards the latter part of the question concerning the amount of current in the neutral wire when each phase is taking 100 amperes—that is, when the phases are symmetrically loaded—the answer is that there will be no current in the neutral wire at all. For if, in Fig 3, O C_1 O C_2, O C_3, are the three currents of 100 amperes each (or of any other amount so long as they are equal), O being the neutral point, then the current flowing into the neutral

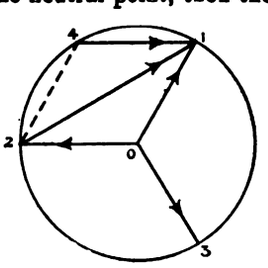

FIG. 2.

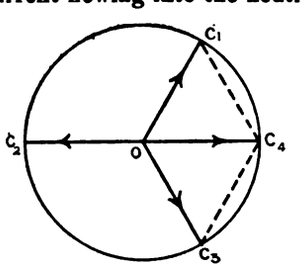

FIG. 3.

wire connected to O (but not shown in Fig. 3) will be equal to the sum of the currents—O C_1, O C_2, O C_3—since the sum of all currents flowing to and from O is zero, according to the usual rule. We have, therefore, to get the value of O C_1 + O C_2 + O C_3, considered as vectors. The sum of O C_1 and O C_3 is the diagonal O C_4 of the parallelogram O C_1, C_4, C_3; and, therefore, O C_1 + O C_2 + O C_3 = O C_4 + O C_2, which is equal to zero, since O C_4 is equal and opposite to O C_2. Hence, if one could be sure of always having balanced phases, there need be no middle wire at all. This, however, is not practicable unless three lamps, one in each phase, can always be used together and switched in or out as a group. As this is probably undesirable, one must consider the conditions due to unbalanced phases. The most extreme case—though very unlikely to occur—is when only one phase is loaded up to 100 amperes. The neutral wire current is then 100 amperes, of course, in phase with the current in the lamps. If O C_1 and O C_3, say, were each 100 amperes, the current in the neutral wire would again be 100 amperes, since O C_4, the vector sum of O C_1 and O C_3, is equal to either of them; and in phase it would be 60deg. ahead of O C_3 and 60deg. behind O C_1. If O C_1 were 100 amperes and O C_3 only 50, say, the current in the neutral wire would again be the vector sum of O C_1 and O C_3, which can easily be shown to be $50\sqrt{3}$, and to be, in phase, 30deg. behind O C_3 and 90deg. before O C_3.

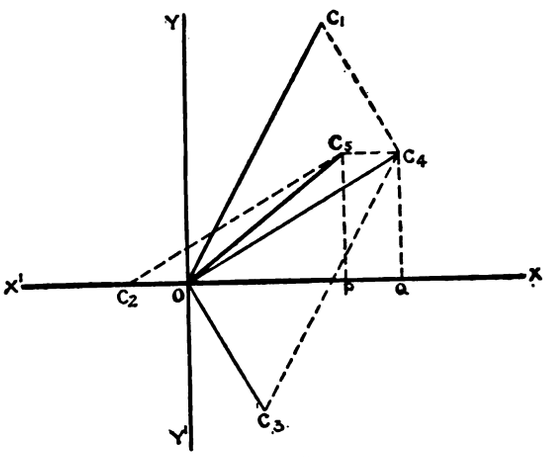

FIG. 4.

Similarly, if there be current in each phase, which will be the case always if the installation be well designed—and the better the design the more nearly equal will O C_1, O C_2, and O C_3 be—the current in the middle wire will be the sum of the three vector expressions for the individual currents. Suppose, for example, O C_1 is 100, O C_2 is 20, and O C_3 is 50, and neglect for simplicity the fact that these will no longer, owing to their want of equality, be exactly 120deg. apart. The arrangement is shown in Fig. 4. O C_4 is the sum of O C_1 and O C_3, and is, by the usual trigonometrical rule, equal to

$$\sqrt{100^2 + 50^2 - 2 \cdot 100 \cdot 50 \cdot \cos 60\text{deg.}}$$
$$= 50\sqrt{3}.$$

O C_5 is the sum of O C_4 and O C_2, and is, therefore, the sum of O C_1, O C_2, and O C_3, or the required result. Its value is

$$\sqrt{(50\sqrt{3})^2 + 20^2 - 2 \cdot 50\sqrt{3} \cdot 20 \cdot \cos 30\text{deg.}}$$
$$= 70.$$

Its inclination to O X is $\tan^{-1} \frac{C_5 P}{P O}$ or $\frac{C_4 Q}{Q O - Q P}$

or,
$$\frac{O C_4 \sin 30\text{deg.}}{O C_4 \cos 30\text{deg.} - O C_2} = \frac{50\sqrt{3} \times \frac{1}{2}}{50\sqrt{3} \times \frac{\sqrt{3}}{2} - 20}$$
$$= \frac{50\sqrt{3}}{110},$$

and
$$\tan^{-1} \frac{50\sqrt{3}}{110} = \tan^{-1} \cdot 787, \text{ or } 38^\circ\ 12'.$$

Thus the current in the neutral wire is 70 amperes, lagging 21° 48′ behind O C_1, lagging 141° 48′ behind O C_2, and leading 98° 12′ before O C_3. Other combinations could be similarly treated, and the current in the neutral wire found graphically for any set assumed.

Just one word, in closing, about a mesh-connected generator (see Fig. 5). Here the neutral point in the generator is imaginary, but a neutral point for the system might be artificially created by coupling up three resistances, O R_1, O R_2, O R_3, in star grouping, and using the point O as the return for the common lead from the lamps, or the earthed point. This would, of course, be economically inadmissible, owing to the waste current always flowing, and it would further necessitate the use of lower voltage lamps, as one resistance of the set would be in series with all the lamps of the corresponding set which happened to be switched in. This would cause great fluctuation in the lamps, owing to varying loss of volts in the resistances. The arrangement is practically impossible, but is mentioned because it is possible to employ it in some special cases of a different

Digitized by Google

nature from the one here. Of course, if the phases could be kept balanced by the arrangement before suggested of always having three lamps, one in each set, switched in or out at a time, the lamps could be star connected to a mesh-connected generator without feeling the want of a neutral wire, as the currents in any two branches would combine to form the equal (in numerical value) current for the third branch, and the volts per branch of lamps would be 254 as before, if the generator voltage were 440, as assumed. But only in this case is it practically possible to run lamps at a

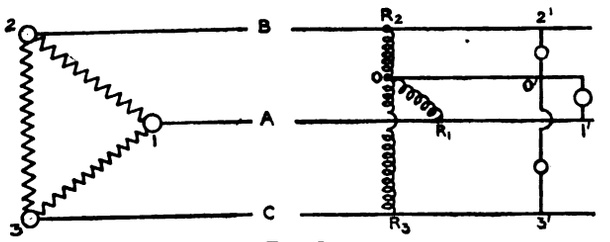

FIG. 5.

lower voltage from a mesh-connected generator. With a star-connected machine it is always possible.—T. C.

Answer to No. 819 (*awarded 7s. 6d.*).—The method suggested in the question of working a combined power and lighting system has often been adopted with success. The arrangement which is shown in Fig. 1 consists of the

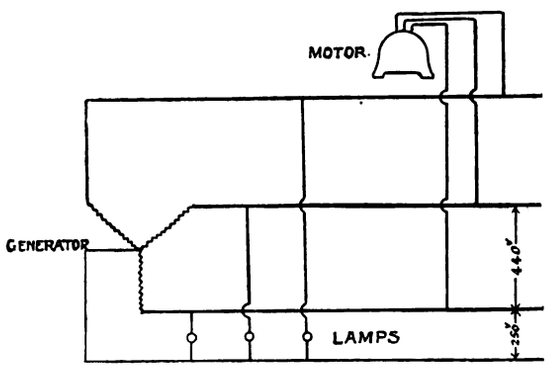

FIG. 1.

three line wires of equal cross-section and a neutral wire usually earthed, the lamps being connected between the neutral and any of the three line wires. The motors take their supply from the three line wires in the ordinary way, and work at the full pressure of 440 volts, while the voltage between the neutral and the outers—*i e*, that across the lamps—will be about 250. The clock diagram in Fig. 2 will explain this. Let the voltages between the

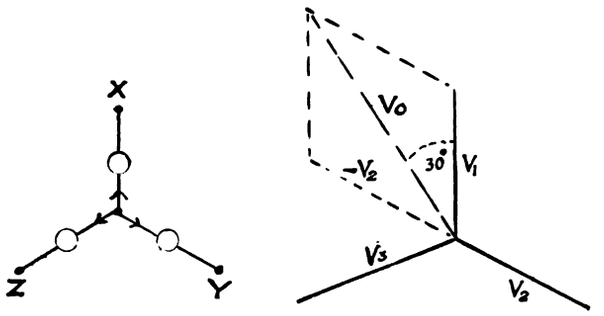

FIG. 2.

neutral and the outers be V_1, V_2, and V_3 respectively, counted positive when they act from the neutral point. The voltage between X and $Y = V_1 - V_2$. Drawing in $-V_2$ and completing the parallelogram, we have the voltage between X and Y = resultant $V_0 = 2\ V_1 \cos 30\text{deg}$.

$$= \sqrt{3}\ V_1.$$

Hence the voltage across the lamps

$$= \frac{440}{\sqrt{3}} = 254.$$

It must be assumed that the lighting circuit originally wired for 240 volts continuous current has sufficient insulation to withstand the increased voltage, which will reach a maximum instantaneous value of $250 \times \sqrt{2} = 350$. It is unlikely that an equal number of lamps will always be connected to the three outers, and, therefore, the neutral wire which will carry the out-of-balance current should be connected to the neutral point of the generating plant, which must be star wound.

If the neutral point of the generating plant is not available, an equaliser can be placed at a suitable point on the system. This is simply a three-phase star-connected choking coil, and the neutral wire is connected to the neutral point. However, the presence of motors on the circuit would have a similar equalising effect. It is supposed in the question that the lamps are taking 100 amperes per phase; the circuits, therefore, are perfectly balanced, and there will be no current in the neutral wire.—H. O. B.

Answer to No. 819 (*awarded 7s. 6d.*).—The method of distribution suggested of using an earthed neutral is quite common in the case of three-phase lighting circuits, and corresponds to the three-wire distribution of continuous current where the middle wire is earthed and used as the common return. Fig. 1 gives a diagrammatic view of the arrangement. The voltage between any two lines being 440 volts, that between either line and the earthed neutral will be $\frac{440}{\sqrt{3}} = 254$ volts, which is the voltage supplied to the lamps. The current flowing in the earthed neutral will depend on the way the phases are loaded relatively to each other. For supposing there are the same number of lamps connected across each phase and the neutral, so that the current in each line I., II., and III. is the same, then

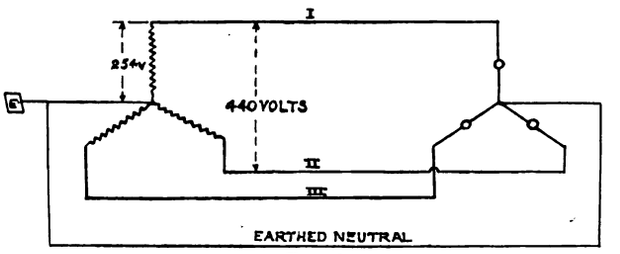

FIG. 1.

there will be no current in neutral. This is readily seen by reference to Fig. 2, in which O 1, O 2, and O 3 represent the currents in each of the three lines I., II., and III., and each being the radii of a circle they are equal in magnitude,

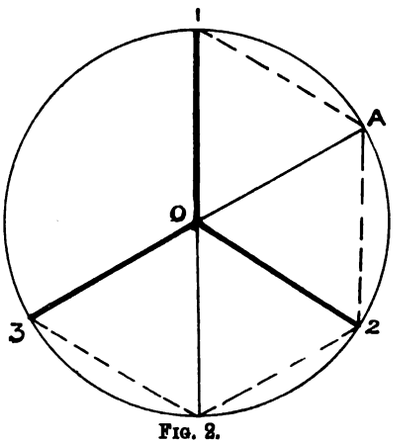

FIG. 2.

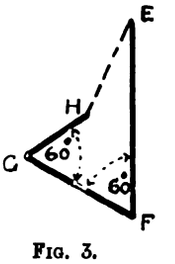

FIG. 3.

and are displaced from each other by 120deg. Now the current flowing in the earthed neutral is the resultant of these three currents O 1, O 2, and O 3, and in the case we are considering is obviously zero. Thus with 100 amperes on each phase the current in the neutral will be zero, and it is quite easy to see that no matter how the load on either phase is varied, provided the load on any one phase does not exceed 100 amperes, the maximum current that will flow in the earthed neutral will be 100 amperes, so that the cross-section of this main need be no greater than that of either of the three mains, I., II., or III. For supposing that O 3 and O 2 are zero, and that O 1 is 100 amperes—*i e*, there is 100 amperes on phase I, and no load on either phases II. or III.—then the

Digitized by Google

current in the neutral must equal O 1—*i.e.*, 100 amperes. Now suppose that the load on phase II. is increased to 100 amperes, the load on phase III. still remaining zero. The current in the neutral will now be the resultant of O 1 and O 2, equal to O A, equal to 100 amperes, and it is readily seen that for any value of O 2 less than 100 amperes, O A will correspondingly be less than 100 amperes. If now load be put on phase III. while the current in phases II. and I. is still 100 amperes, the current in the neutral will decrease in value, for this must always be the resultant of O A and O 3—*i.e.* (O A – O 3)—because, from the symmetry of the diagram, O A and O 3 lie in the same straight line. When O 3 = O A—*i.e.*, when all the phases are equally loaded—the current in the neutral will be zero, as was shown to be the case previously.

Fig. 3 shows a rapid vectorial method of arriving at the value of the current in the earthed neutral. In this diagram we have

E F = current in phase I.,
G F = current in phase II.,
G H = current in phase III.,
then E H = current in the neutral.

The voltages across the phases should be very evenly balanced, no matter how each phase is loaded, for the employment of an earthed neutral tends to equalise the voltages.—A. P. Y.

Answer to No. 819 (*awarded* 5*s.*).—In this three-phase plant the lighting could be satisfactorily and more economically carried out without the use of transformers by adopting the method illustrated in Fig. 1. As the

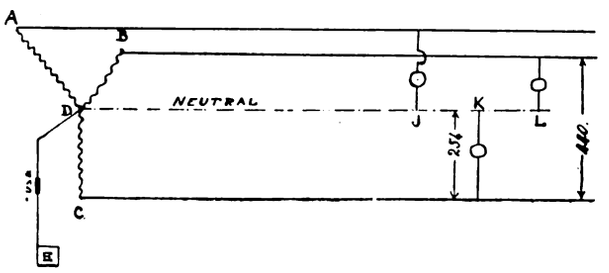

FIG 1.

generator has a neutral point (which it is intended to earth), it must be "star" wound; then

Voltage between any two line wires = 440.

Voltage between any line wire and neutral

$$= \frac{440}{\sqrt{3}} = 254.$$

So, while motors would be connected across the 440-volt leads, lamps could be run between the neutral and either A, B, or C at 254 volts. When the lighting load is 100 amperes on each phase, then current returning to generator by the neutral is zero, and the only currents in neutral would be between the points J, K, L.

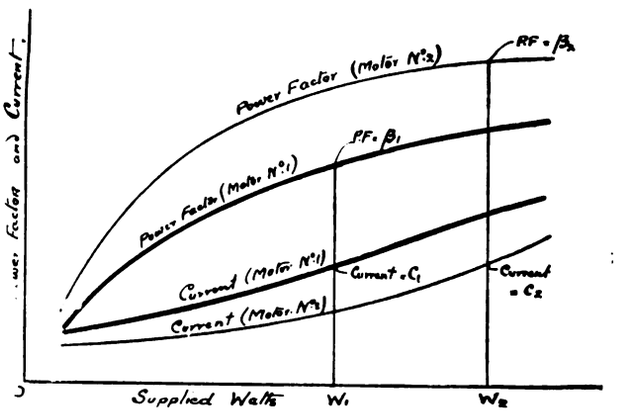
The lighting load, if properly distributed between the three phases and neutral, would produce no voltage regulation difficulties at the generator end.

It would be well to place a fuse between the point D on generator and earth-plate, so that if one feeder became earthed at any point the fuse would blow, but the system would still continue to work satisfactorily, and the fault could be repaired at leisure.—W. C. S.

Question No. 820.—Two single-phase induction motors of exactly same horse-power but by different makers, when doing similar work require exactly same current and same voltage. Wattmeter, however, on motor No. 1 registers only two-thirds that of meter on No. 2. (1) Is this because power factor of first motor is only two-thirds that of power factor of No. 2? (2) As current × voltage is much greater than watts paid for, who pays for lost energy? (3) Does not the above point to the suggestion that if two motors of similar amperage give same torque, but that one has lower power factor than the other, the lower power factor one is cheaper to run from consumer's standpoint?

Answer to No. 820 (*awarded* 7*s.* 6*d.*).—The watts supplied to either motor, after deducting the losses occurring in the motor itself, represents the power required to do the particular work with which that motor is connected. Although no idea of the size of these motors is given in the question, we can safely assume that the losses occurring in either motor at full load will be something of the order of 5 per cent. of the full-load output. As the motors will doubtless be working very near their full-load horse-power, we may neglect the losses and assume that the watts supplied to each motor is a measure of the work done by that motor. If both the wattmeters are reading correctly, then we must conclude that the work done by motor No. 1 is only two-thirds of that done by motor No. 2; and, further, if the motors are doing similar work—*i.e.*, the torque exerted by each is the same—then the only way we can explain this difference in the supplied watts is that the speed of motor No. 1 is only two-thirds of the speed of motor No. 2. This would be the case if motor No. 1 had $1\frac{1}{2}$ times as many poles as motor No. 2, or supposing No. 1 was a six-pole motor and motor No. 2 a four-pole motor.

If the above supposition be correct, we can easily show how it is possible that the current taken by each motor is the same, although the work done by one motor is only two-thirds of the work done by the other. In the diagram curves are shown which indicate how the power factor and current vary with the supplied watts in the case of each motor. These curves are shown slightly different for the two motors for the purpose of arriving at the desired result, and as the motors are by different makers this assumption is not unwarranted. The thick-line curves are for motor



No. 1 and the thin-line curves for motor No. 2, and supposing the watts supplied to motor No. 2 to be represented by O W_2, then the watts supplied to motor No. 1 will be represented by O W_1, where O $W_1 = \frac{2}{3}$ O W_2. We also have that, corresponding to W_2 watts supplied to motor No. 2, the power factor is β_2 and the current C_2, and, further, corresponding to W_1 watts supplied to motor No. 1, the power factor is β_1 and the current C_1. For this particular set of curves we see that $C_1 = C_2$, and consequently $\beta_1 = \frac{2}{3}\beta_2$, which means that the current supplied to each motor is the same and the power factor of motor No. 1 is only two-thirds of the power factor of motor No. 2, which is the result observed by "Amateur."

Parts (2) and (3) of the question will be easily answered if "Amateur" remembers that

$$\text{power factor} = \frac{\text{supplied watts}}{\text{current} \times \text{volts}},$$

or, $$\text{supplied watts} = \text{P.F.} (\text{current} \times \text{volts}).$$

What his meter registers and what he pays for is *supplied watts*, and not current, and if the power factor in one case is smaller than in the other, the current in each case being the same, it only means that the watts supplied in the one case is smaller than that in the other, and the motor, of consequence, is doing less work, as was shown to be the case previously. As a matter of fact, a small power factor is a disadvantage, in so far that for the same supplied watts the current varies inversely as the power factor, so that with a small power factor the current is unnecessarily large, giving appreciable C^2R losses, which are paid for by the consumer.—A. P. Y.

[Other replies to Question No. 820 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

QUESTIONS.

826. What is meant by the all-day efficiency of a transformer? What are the factors to be taken into account in the design of the transformer in order to secure a high all-day efficiency?—T. J. M.

837. Explain clearly, with diagrams if necessary, the "La Cour" system of compounding motor-generators.—M. G. TWEEDIE.

ANSWERS.

Question No. 820.—Two single-phase induction motors of exactly same horse-power but by different makers, when doing similar work require exactly same current and same voltage. Wattmeter, however, on motor No. 1 registers only two-thirds that of meter on No. 2. (1) Is this because power factor of first motor is only two-thirds that of power factor of No. 2? (2) As current × voltage is much greater than watts paid for, who pays for lost energy? (3) Does not the above point to the suggestion that if two motors of similar amperage give same torque, but that one has lower power factor than the other, the lower power factor one is cheaper to run from consumer's standpoint?

Answer to No. 820 (*awarded* 7*s.* 6*d.*).—The fact that both motors take the same current when doing the same work indicates that the product of power factor × efficiency is the same in the two cases. The motor which takes the lower number of true watts must be doing so simply because its efficiency (ratio of output watts to true input watts) is higher than that of the other motor in the ratio of 3 : 2, so that with only two-thirds of the input watts the output at the pulley is the same. Since the product of power factor × efficiency is constant, the power factor of the high-efficiency (low true watt) motor must be lower than that of the other motor in the ratio of 2 : 3. In the design of induction motors it is often possible to alter the power factor at the expense of the efficiency in this way. Thus, supposing that whilst retaining approximately the same diameter and length of rotor, one of the makers employs a considerably shorter air-gap than the other. The number of stator turns in the small air-gap motor could then be reduced so as to work at a higher flux density, and yet the power factor would be higher than in the other motor. The fewer turns would somewhat reduce the stator $C^2 R$ loss, but the higher flux density would decidedly increase the iron loss, which is usually the more important, so that the efficiency would, on the whole, fall. The net result would be a motor of higher power factor but lower efficiency, though so large a difference as in this case (in the ratio of 2 : 3) is quite unusual between motors by recognised makers.

With regard to the second part of the question, the true watts (as shown on a wattmeter) are the only ones usually paid for, as they are the only ones which directly require engine power to produce them. The "idle current," which is out of phase with the voltage and causes the difference between the product of volts × amperes and the true watts, is objectionable in the way of causing drop in the leads and drop in the alternator voltage through armature reaction, but it is essentially a wattless current and requires no expenditure at the generating station. In some stations it is the custom to make a small additional charge, based on the amount of this wattless current, over and above the ordinary charge for the true watt-hour consumption. When no such charge is made, it is obvious that the motor with the highest true watt efficiency (quite independently of whether it has a high or a low power factor) is the best from the consumer's point of view, as this will be the one which for a given useful output takes the least true input watts.—Q.

Answer to No. 820 (*awarded* 5*s.*).—I think the great difference in the readings of the two wattmeters must be due to their inaccuracy, and not to the motors. One could understand a difference of 1 or 2 per cent. in the motors, but hardly 33 per cent., as "Amateur" states. A simple method to test this would be to change over the meters. If this be done, I expect it will be found that the motor which was before registering most is now registering least. It will now be necessary to have one or both of them recalibrated. If the above is not the cause (but I rather expect it is), we must look elsewhere. Now, inasmuch as the current to the two motors is the same, it would appear that the work done by the two machines is about equal, providing the power factors and efficiencies are also about the same, and, therefore, the inputs are expected to be about similar, under these ordinary conditions. As they are not, we must look for the cause to either the power factor or the efficiency. The power factor of an induction motor such as this may be anything up to about ·8, depending on the size of the machine and its load, the aim of the makers being to get as high a power factor as possible. Assuming that in the case of motor No. 2 the power factor = ·7, and the input is x_2 kilowatts, then motor No. 1 must have a power factor of only $\frac{2}{3}$ of ·7 = ·47, because $x_1 = \frac{2}{3} x_2$ and the volts and amperes are the same in both cases. If the two motors are anything like fully loaded, I don't think it likely that one of them will only have a power factor of ·47. A motor is designed to have as good a power factor as possible so as to keep down other losses and improve the efficiency. One could understand a small variation of 5 or 6 per cent. in this owing to the difference in make, as one machine may be more liberally designed than the other and one may be designed for best power factor at full load whilst the other might be at three-quarter load, and so on. The fault must lie in the accuracy of either the wattmeters or the ammeters, either of which could account for this discrepancy.

Turning now to the second portion of the question as to who pays for lost energy, the answer is the electricity works. This lost energy all goes in heat in the machines and lowers the station efficiency. The lower the power factor of the whole system the greater must be the current supplied for the output required, hence the losses which are proportional to the current are increased. The chief of these is the $C^2 R$ loss. It is these extra losses over and above what there would be supplying the same output with a power factor of unity which represent the lost energy, which has to be met by the electricity works.

The last part of the question as to the advisability of using motors of low power factor from the consumer's point of view is certainly a novel one. If with unity power factor it takes a certain current at the supply pressure to do a certain amount of work with a certain efficiency, then with a lower power factor it will take more current at that pressure to do the same work; hence the current losses in the machine are now increased, and the efficiency must go down, and so we have in no way bettered things, but the reverse. The following will make this plain:

$$\text{Watts input} - \text{losses} = \text{watts output},$$
$$E \times C \times \cos\phi - C^2 R = \text{watts output}.$$

Now, assuming E constant, it will be seen that in the first expression C is inversely proportional to $\cos\phi$, the power factor. If we halve $\cos\phi$ we must double C, the current to keep the input the same, but the losses $C^2 R$ will now be four times as great as before, and, therefore, for the same output to make up for the added losses the input must be increased, and hence our efficiency is lowered. Of course, if two motors can be found to do the same work, taking the same current at the same pressure, one having a lower power factor than the other, from the consumer's point of view it is advisable to use the one with the lower power factor, but it will be found that in reality there is very little to be made out of it this way, and it would be well to see that really you are improving the efficiency. I think the above should have made all the points in the query quite plain.—E. R. ALEXANDER

Answer to No. 820 (*awarded* 5*s.*).—As a basis to work upon, let us assume that the power factor of motor No. 2 is unity and that the true watts are 100. Then the true watts will equal the apparent watts, as

$$\frac{\text{true watts}}{\text{apparent watts}} = \text{power factor},$$

that is,

$$\frac{100}{100} = 1{\cdot}00.$$

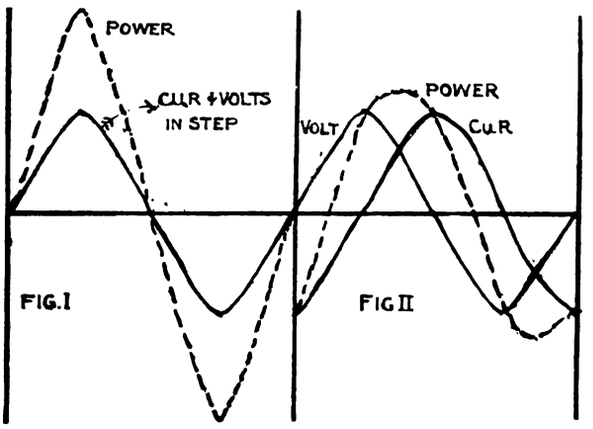
Now, in motor No. 1 the true watts (according to meter) are only two-thirds of the (true watts on other motor, or

Digitized by Google

apparent watts on other motor, and apparent watts on each machine are alike) apparent watts.

$$\therefore \text{ the power factor will be } \frac{66{\cdot}6}{100}, \text{ which is } {\cdot}66.$$

Here we have two motors supposed to be doing the same amount of work, and the one with the worst power factor only costing to run it two-thirds of the price that the other costs with a power factor of unity. Which is absurd. Either the motors *cannot* be doing the same amount of brake horse-power or the meters are wrong. An increase in the power factor always means an increase in the economy of working. If a motor is taking full load current and the power factor is ·50, then the motor is only



doing half load, but full-load losses are going on in the machine, so that the consumer will have a little disadvantage; but the main trouble of inefficiency will fall upon the power station, and it is in their own interest to keep the power factor as near unity as possible all over the system. For a given load and potential difference the current varies inversely as the power factor. Hence, the rate at which energy is dissipated by heating of the circuit will vary inversely as the square of the current. In Fig. 1 the power curve is shown with the volts and current in step. In Fig. 2 the current lags 45deg. and the power factor is ·5. It will readily be seen the importance of a good power factor.—F. B. M.

Question No. 821.—In a certain power station it is desired to test a 700-kilovolt-ampere two-phase alternator, direct coupled to a triple-expansion Belliss engine, for the steam consumption—*i e*, pounds of water—per kilowatt-hour. There is available a water resistance capable of taking 1,200 kw., if required. The set has its own condenser—steam-driven air and circulating pump. There is a feed tank 12ft. by 7ft. by 6ft., into which several condensers discharge, the temperature being from 80deg. to 120deg. F. The feed to the boilers being pumped from this tank through an economiser to the boilers (Babcock and Wilcox, Meldrum Koker stokers, and forced draught), the steam for the jets can, if necessary, be supplied from an independent boiler. It is not required to take into account the steam used by the condensing plant. It is proposed to run the test for five hours. Is this long enough? Please give full details of the usual method of conducting such a test, especially the best way of measuring the water at the hot-well, the various readings required, etc. Also name any good practical books dealing with engine and boiler tests (not American). The steam pressure at the engine stop valve is 170lb. with about 100deg. F. of superheat.

Best Answer to No. 821 (*awarded* 10*s.*).—From the reading of question it is taken that the steam set only is to be tested. As this is so, it will not be necessary to interfere with the usual working of the boiler-house, and steam can be taken from either ring-main or header, as the case may be. The steam for jets can make no possible difference, the test being for steam used, not for coal burnt or water evaporated. It is stated that steam used for condensing plant is not to be taken into account. This is a bit difficult if the exhaust from air-pump, etc., is led into condenser, and can only be calculated approximately by taking indicator cards from pump engines and working out the steam consumption from same. The method for doing this can be found in any text-book on steam. If steam from auxiliaries is put through a feed-water heater, then they have to be left out of account altogether.

With regard to duration of test, a lot depends on reason for testing the set, but it is certain, if a thorough test is to be made, five hours will not be sufficient. It is impossible to get any satisfactory readings with less than one hour's run on each different load. Assuming that five hours is all that can be spared, the run should be as follows: 1½ hours quarter load condensing, 1½ hours half load condensing, 1½ hours full load condensing, ½ hour overload condensing.

In describing test it will be advisable to list the various instruments and appliances necessary, then to place the observers with the readings to be taken, afterwards giving a short description and analysis. Starting at engine, the following instruments are necessary: (1) steam pressure gauge on boiler side of stop valve; (2) steam pressure gauge on high-pressure steam chest; (3) intermediate-pressure receiver gauge; (4) low-pressure receiver gauge; (5) vacuum gauge on exhaust pipe; (6) mercury-cup with thermometer reading to 500deg. F. Nos. 1, 2, 3, and 4 are usually supplied by the engine builders, and No. 5 either by engine makers or condenser manufacturers; Nos. 1 and 5 should be checked before commencement of test by other standard gauges. (7) Six high-speed indicators for each end of all three cylinders, with magneto attachment to same; (8) mercury-cup, with thermometer reading up to 200deg. F. on air-pump discharge; (9) tachometers and steam indicators for steam ends of pumps; (10) two tanks, which have previously been calibrated and marked off (see Fig. 2); (11) one two-way cock or two-lever sluice valves, interlocked, say, 6in., with all pipes necessary from air-pump to the two tanks mentioned above; (12) a large quick-acting sluice valve, say 10in., on each tank, with pipes leading to hot-well mentioned in question.

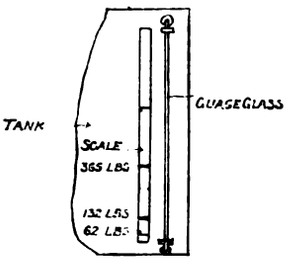


FIG. 2.

This is a fairly complete bit of mechanical apparatus. The electrical portion of test is as follows: On the supposition that the machine in question is connected to the 'bus bars and has previously been in use, it will be necessary to disconnect the 'bus-bar side of switch from the bars. The leads should be taken from switch through any instruments that are on panel to the water resistance. Between the switch and water-box a load panel should be inserted. This load panel should be fitted with properly calibrated and guaranteed instruments, which probably will be supplied by the alternator makers, or could be loaned from a firm of instrument manufacturers. The following is a list of electrical apparatus: (13) main switch, capable of breaking 1,000 kw.; (14) field switch; (15) field ammeter; (16) synchronising appliances. The above will be on machine panel of main board, if same is used. (17) two ammeters, one on each phase; (18) two voltmeters, one on each phase; (19) two single-phase wattmeters; (20) an oil switch capable of breaking the maximum load. Nos. 17, 18, 19, and 20 should be on load panel. From here leads can be taken to the water resistance. This should be adjustable with leather thongs from top of rod, over a pulley down to within reach, so that the load can be altered whilst the tanks are alive. If the machine is of high voltage, the attendant should wear rubber gloves as an additional safeguard.

Method of Test.—When all connections are complete and have been made, including a trial run, it will be necessary to place the various assistants in their positions. It is not possible to state exactly how to place the men without knowing the locality, capability of assistants, etc. The various observation sheets properly marked off and ruled, as shown under, should be handed to each observer. With each set of sheets should be included a board fitted with clips to hold sheets, and a place assigned for same to be placed. The various sheets for different observers are marked A, B, etc. A list is given herewith. The engine

Digitized by Google

driver should be quite capable of looking after engine and reading the various gauges on same, including the temperature of steam. These readings to be entered on sheet A. An experienced assistant must be on engine-platform to take indicator cards. These should be marked at once "L P.," "I.P.," and "H P.," and top or bottom end also numbered and time noted (sheet B). It will be necessary to have an observer on the condenser to read the vacuum, speed of pumps, and also to take indicator cards if necessary (sheet C). Another observer must be at the two tanks, 10, to work the interlocked sluice valves and take

minute intervals are used, it is very easy to convert same into hours. Of course, it will be noted that E and F are a check on one another, and that the readings entered on F sheet are readings from correct instruments. The results are very easily worked out, and do not need explaining, being

$$\frac{\text{Water in 6 minutes} \times 10}{\text{average kilowatts in one hour}} = \text{steam per kilowatt-hour.}$$

The steam consumption can also be worked out per indicated horse-power and per electrical horse-power.

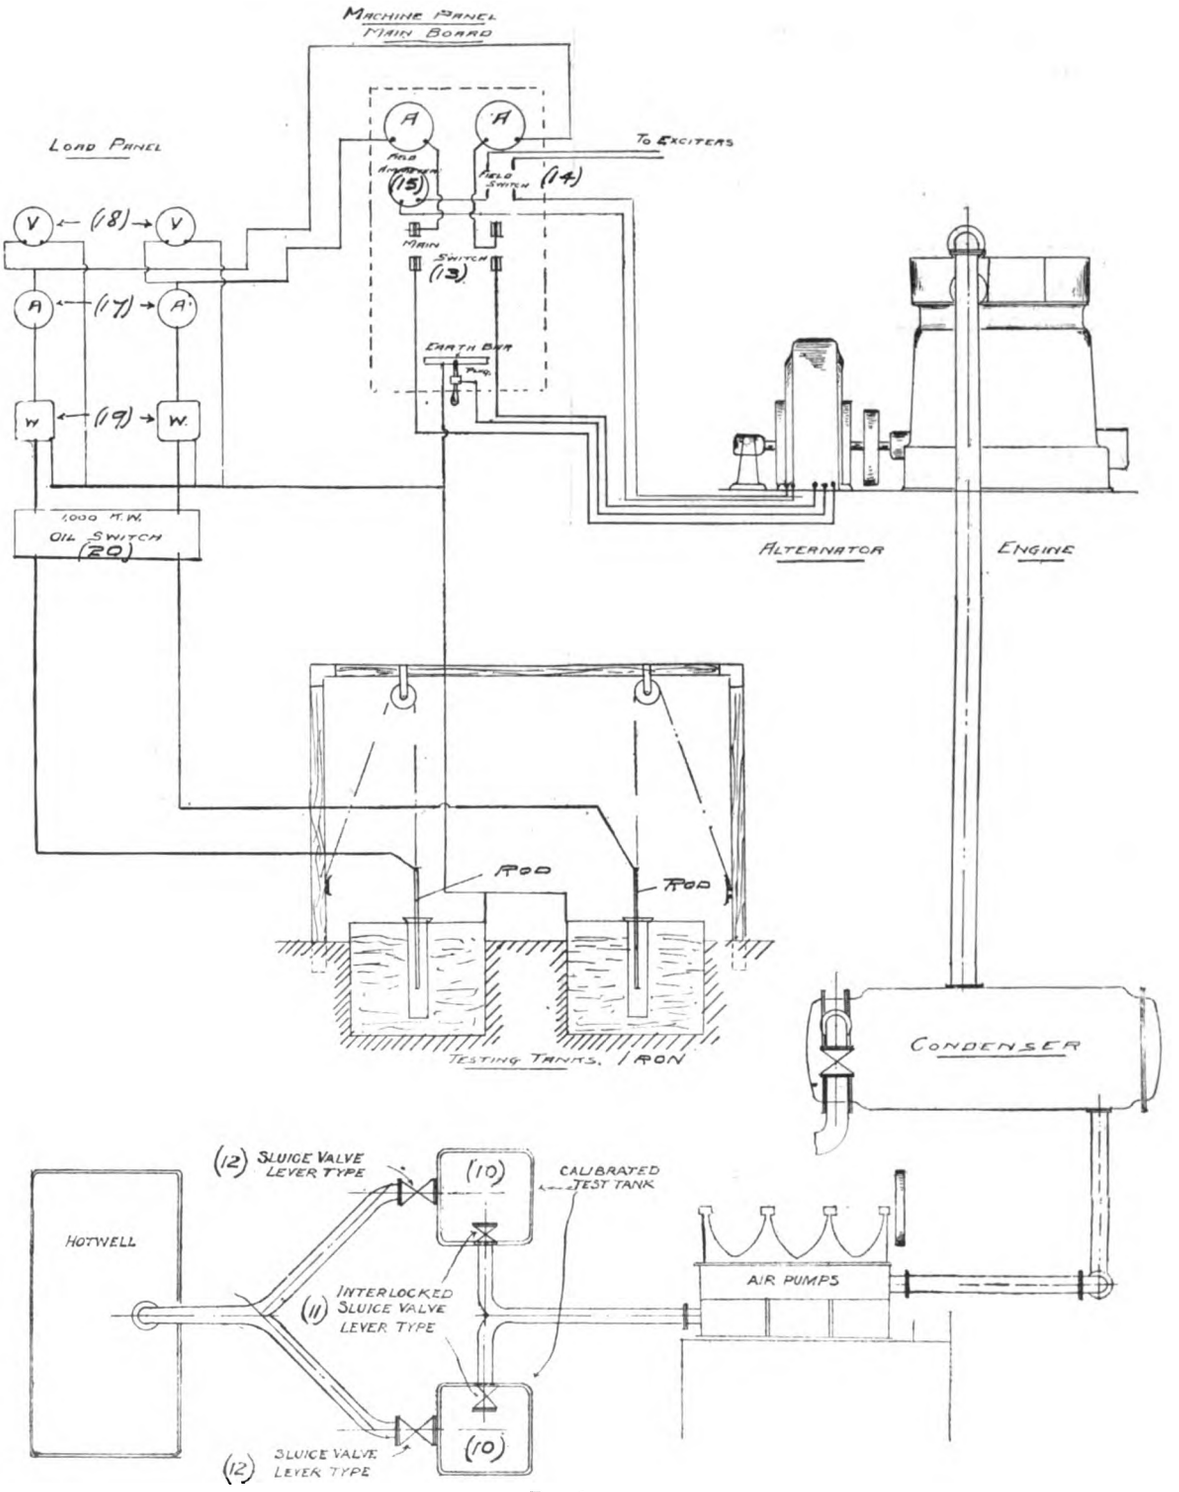

FIG. 1.

the readings on tank before opening the sluice valve to let the water into hot-well (readings sheet D). An observer will be required on the machine panel of main board to take readings as on sheet E, and also to operate switches in case of need and to adjust field. An experienced assistant must attend to load panel and enter readings on sheet F, also to control a man in charge of the water resistance.

All being ready, it should be agreed to start at a certain time and to take observations every six minutes. If six-

A good work on engine and boiler testing is by Prof. Pullen, and is published by the Scientific Publishing Company, Manchester.—J. H. S.

Answer to No. 821 (*awarded* 7*s.* 6*d*)—The test which "Electron" proposes to take upon his plant is the simplest it is possible to take, and yet the results to be obtained are the most important, since pounds of water per kilowatt-hour represents the true efficiency of the combined plant, and upon this result the performance of the plant is always judged. There are two sets of readings to be taken: the first on the steam side, and the second on the electrical side. I will deal with the steam side first. The thing, of course, to be measured is the water taken by the engine. This can be best done by measuring the discharge from the condenser. "Electron" states that several other condensers discharge into the tank into which our condenser discharges. This, of course, will not do. If the other condensers are not in operation at the time of taking the test, all well and good, but if they are in use, either their discharge must be diverted or another tank must be obtained into which our condenser may discharge. This latter will, I think, be the better plan, because it must be understood that as we are going to measure the discharge from the condenser we cannot straightway take the water again for feed purposes until it has been measured. The arrangement will then be this: the condenser will be discharging into tank A, from which the water is periodically discharged into a special measuring tank, B, and after measurement the water is run from B into tank C, from which the boilers feed. The measuring tank, B, will, of course, have to be accu-

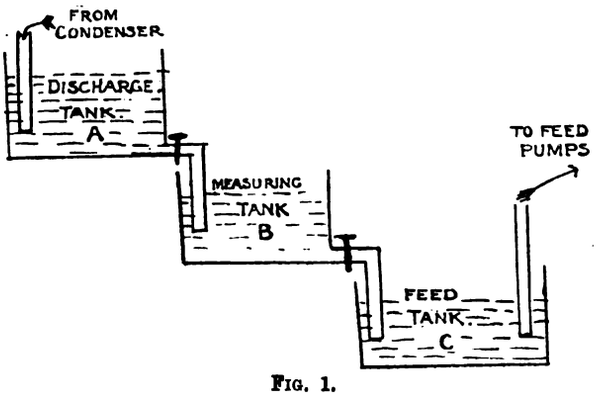

FIG. 1.

rately calibrated previously, and an easily distinguished mark made upon it indicating that up to this mark represents a certain known weight or volume of water. The procedure during the test will then be to fill the measuring tank, B, at intervals from the tank A up to the mark, then cut off the supply from A, and empty tank B into tank C, and, when empty, turn off the tap and refill again from A when necessary. All leakages *on the exhaust side* of the engine will have to be carefully collected and weighed during the time the test is on. Now, as regards the readings to be taken on the electrical side. In circuit with the alternator will be connected an ammeter, voltmeter, a two-phase watt-hour meter, or two single-phase meters. The above watt-hour meters must be of great accuracy. The connections are shown in Fig. 2. It will, of course, be necessary during the test to keep the load as constant as possible. The reading of the watt-hour meter must be taken before and after the test, the difference, of course, giving the power generated. In Fig. 2 A represents an ammeter, V a voltmeter, W the two-phase watt-hour meter, and R the water resistance.

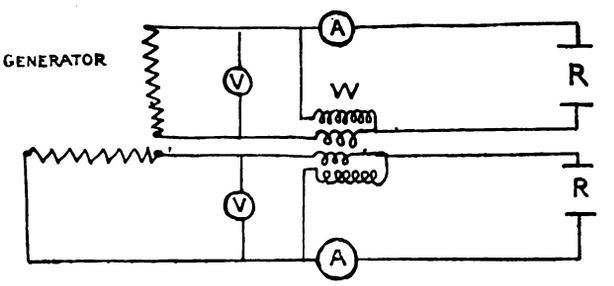

FIG. 2.

I will now proceed to describe the general procedure in taking a test. First of all, I would remind "Electron" that we are not taking a boiler test, and therefore it is absolutely unnecessary to prolong the test for five hours. Half an hour's duration is quite long enough for a test once everything is in full swing, but, of course, it is as well to repeat the test once or twice in order to check the results obtained. Half an hour's test will give results quite as accurate as five hours. The first thing to be done is to make everything ready for the test, as I have previously described. The machine, of course, will be plugged on to a spare set of 'bus bars or temporary leads taken from its terminals to the testing tank outside. Then the engine is started up and the generator put on to its full normal load, or any other load at which it is desired to test it, by means of varying the distance apart of the plates of the water resistance. The boiler pressure, the vacuum, etc, must all be at their normal values, and kept as constant as possible. The set had better be run half an hour before any test is taken, to allow everything to reach its normal condition. There is one small difficulty which presents itself, and that is the method of turning the condenser discharge into tank A at the precise instant of commencing the test. The best way of doing this is, I think, by means of a flexible pipe connected to the condenser discharge pipe. The water discharged is allowed to run to waste until the signal to commence the test is given, when the operator puts the end of the flexible pipe over the tank A, allowing the discharge to run into this tank.

The signal to commence the test had better be given by means of an electric bell to the operator in charge of the water measurement. Then, on the signal being given, the water is allowed to run into the discharge tank, the reading of the watt-hour meter taken, and also the time of the commencement of the test. The test should be run for about half an hour; the actual time is not particular. At the end of the test the signal to stop is given, and the condenser discharge is diverted from the tank A. The watt-hour meter reading is also taken. As I have previously described, during the test the water is run from the tank A into tank B and measured. Shortly after the finish of the test the operator in charge of the condenser discharge will be able to give the weight of water discharged. The differences of the meter readings will give the kilowatt-hours used, and then, of course, we have that

$$\frac{\text{Total condenser discharge}}{\text{kilowatt-hours}} = \text{pounds of water per kw.-hour.}$$

All leakages on the condenser side of the engine are, of course, as I have described, included in the numerator. A second and third test may now be taken. I myself have often used this method, and I think it the best one to use.

"Engine Tests and Boiler Efficiencies," by J. Buchetti, is a good book on the subject.—ERNEST P. HOLLIS.

[Other replies to Question No. 821 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

840. Is there any formula giving for a magnetic blow-out the connection between sparking distance, voltages of supply, current to be broken, distances of the pole-pieces, and number of ampere-turns on blow-out coils?—J. S.

ANSWERS.

Question No. 821.—In a certain power station it is desired to test a 700-kilovolt-ampere two-phase alternator, direct coupled to a triple-expansion Belliss engine, for the steam consumption—*i.e.*, pounds of water—per kilowatt-hour. There is available a water resistance capable of taking 1,200 kw., if required. The set has its own condenser—steam-driven air and circulating pump. There is a feed tank 12ft. by 7ft. by 6ft., into which several condensers discharge, the temperature being from 90deg. to 120deg. F. The feed to the boilers being pumped from this tank through an economiser to the boilers (Babcock and Wilcox, Meldrum Koker stokers, and forced draught), the steam for the jets can, if necessary, be supplied from an independent boiler. It is not required to take into account the steam used by the condensing plant. It is proposed to run the test for five hours. Is this long enough? Please give full details of the usual method of conducting such a test, especially the best way of measuring the water at the hot-well, the various readings required, etc. Also name any good practical books dealing with engine and boiler tests (not American). The steam pressure at the engine stop valve is 170lb. with about 100deg. F. of superheat.

Answer to No. 821 (*awarded 7s. 6d.*).—In order to carry out this test, we have two measurements to make: (1) the output of the generator, (2) the steam consumption of the engine. The first of these measurements presents no serious difficulties. The machine would be loaded on the water resistance, care being taken to see that both phases are equally loaded, and readings taken on the

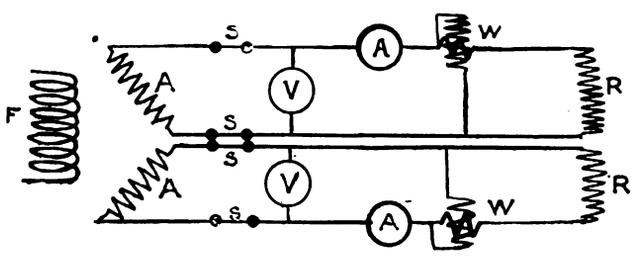

FIG. 1.—F, Alternator Field; A A, Alternator Armature; S S S, Switches; V V, Voltmeters; A A, Ammeters; W W, Wattmeters; R R, Water Resistance.

necessary instruments; the latter might be arranged as in Fig. 1. If the set is already installed, the instruments will probably be found already connected up on the switchboard. The idea of inserting a wattmeter as well as a voltmeter and ammeter is to enable the power factor to be determined. This will be fairly high, as the only inductive resistance in circuit will be that in the machine itself. The second item is not so easily obtained. There are several methods open, and we shall proceed to discuss a few of the most promising ones. In order to make a continuous measurement of the steam consumption over the whole test, one of the following methods may be employed: (1) two separate tanks on separate platform weighing machines; (2) two separate calibrated tanks, or one with a divided partition; (3) weir; (4) measuring tube; (5) meter. If it be deemed sufficient to measure the steam consumption by alternately filling and emptying a single tank, single tanks may be used in Nos. 1 and 2. When considering the above methods in rather more detail, we must remember that we have a flow of something like 250lb. per minute to provide for.

Weighing-Machine Method.—As we must have a tank capacity for at least five minutes, we shall require two tanks 3ft. by 3ft. by 3ft. and two weighing machines with a range up to three-quarters of a ton, and as continual weighing is necessary it will be seen that this method is far from convenient. If two tanks are employed, some device must be used to facilitate changing over from one tank to the other. A very satisfactory arrangement is shown in Fig. 2. The pipe, A, is clamped to the side of one of the

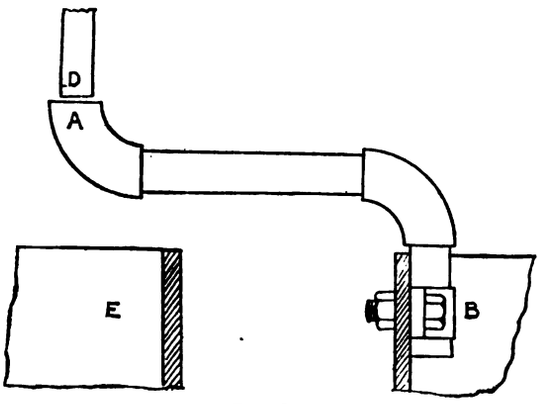

FIG. 2.

tanks, B, in such a manner that it can be moved at right angles to the plane of the paper, and so by swinging the end, A, under the delivery pipe, D (a temporary diversion of the pipe from condenser to hot-well), or clear of it, the water can be diverted into the tank B or fall direct into the tank E. The connection A should be made amply large in comparison with D in order to allow the water a free passage. If one tank only is employed, the drain pipe or pipes should be as large as possible so that a minimum amount of time is lost while emptying the tank. A modification of the one-tank method, which enables continuous measurements to be made, is shown in Fig 3 Here the

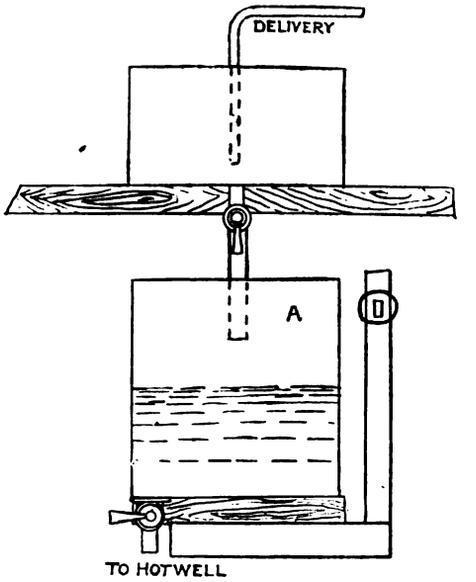

FIG. 3.

water delivered while the lower tank, A, is being weighed and emptied is stored in the upper tank, B, and afterwards allowed to enter the lower tank and be weighed. Of course, this auxiliary tank need only have about half the capacity of the weighing tank. With regard to the weighing machines, these are sometimes arranged so that when the weighing lever rises it makes an electrical contact and rings a bell. The jockey weight is set at, say, 100lb., plus the weight of the tank; then, as soon as 100lb. have

Digitized by Google

entered, the lever rises and rings the bell, on hearing which the observer notes the time. The jockey is then moved another 100lb, and so forth.

By Means of Calibrated Tanks.—Where a large platform weighing machine is unavailable, it may be found convenient to measure the water by volume rather than by weight. A divided tank arranged for experiment is shown in Fig. 4. To calibrate the tanks, known weights of water

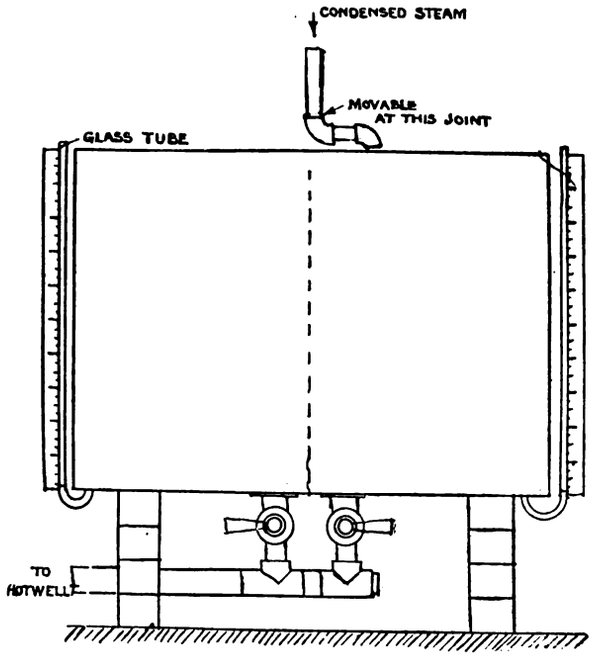

FIG. 4.

are introduced, and the height of the water in the tanks observed by means of ordinary inch scales placed alongside the gauge glasses. These scales may either be made permanent and a calibration curve co-ordinating weight of water and height in tank used, or a scale (on paper will do) may be made which will read pounds of water directly. This latter method is preferable.

By Means of a Weir.—Both the foregoing methods require constant attention, and No. 1 is especially tedious in working. By means of a weir, which is easily and inexpensively constructed, a continuous measurement of any quantity of water (condensed steam), however large, can easily be made. A suitable arrangement is shown in Fig. 5.

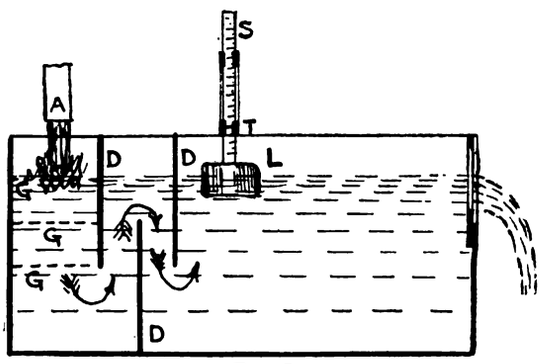

FIG. 5.

The water enters at A, and immediately encounters two or three horizontal sheets of perforated zinc, through which it passes; it then moves under and over the diaphragms, D, and after passing slowly over the rest of the tank falls over the weir, which *must* have sharp edges. The width of the tank should not be less than three times the width of the weir, and the depth of the tank not less than three times the maximum head over the weir. A float, L, made of thin sheet copper attached to a boxwood, brass, or aluminium scale indicates the position of the water-level in the tank. For good results, L should not be less than 2ft. from the weir. The scale may be guided in any suitable manner, remembering that friction must be minimised as much as possible, and an index fixed to the tank must also be provided. A fine brass or copper wire soldered to one of the guides is very suitable for this purpose. The quantity of water passing over a rectangular weir is given by

$$\text{pounds per minute} = 320{\cdot}6\ C\ d\ b\ h^{\frac{2}{3}},$$

where h = head of water above the bottom edge of the weir in feet;

b = breadth of the weir opening in feet;

d = density of water in pounds per cubic foot;

C = coefficient of discharge.

Unfortunately C varies with the head and the width of the weir, so that each weir must be separately calibrated. The method of doing this is perfectly simple: water is allowed to flow over the weir under various heads, and the flow determined by catching and weighing the amount discharged in a certain time. One point, however, requires notice, and that is the determination of the zero reading or level of the lower edge of the weir. Fig. 6 shows the method of doing this. The screw, Q, which is supported

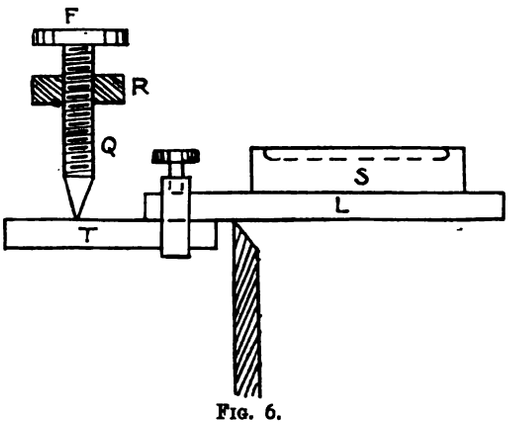

FIG. 6.

from a bar, R, attached to the tank, is screwed down until the level, S, indicates that the strips, L and T, are level; T, L, and S are then removed, and the tank filled until the surface of the water just touches the point of the screw; the zero reading on the scale is then taken. A V notch might be used instead of a rectangular weir; this gives a more constant coefficient of discharge, but is rather more difficult to make satisfactorily.

By Means of a Measuring Tube.—This is an extremely cheap and convenient method, and in practice is found to give very fair results. The arrangement is shown in Fig. 7, which practically explains itself. Although the scale, which reads directly in pounds per minute, can be made from theoretical considerations, it is best made experimentally. For the purposes of this test a 5ft. tube, having three $\frac{1}{2}$in. holes in the bottom plate, would probably be sufficient.

By Means of a Meter.—It may be found convenient to measure the condensed steam by means of a water-meter, though it should only be used where other methods are impracticable. A positive meter should be employed, and should be carefully calibrated before and after a trial. Both Kennedy's and Schonheyder's are good types; the latter is made to take water up to a temperature of 300deg. F.

With regard to the trial as a whole, five hours is ample; in fact, four hours only should be devoted to taking observations, the set being run on load for about an hour to get everything settled down. After starting up the set, the load should be put on and adjusted to the required value, and the set allowed to run about an hour, during which time the steam-measuring appliances, whichever selected, should be tested and all the drain cocks, etc., closed. At the end of this time observations should be commenced; the observer on the generator should take readings every five or ten minutes, keeping the load as steady as is possible. The observer measuring the steam, if methods (1) or (2) be chosen, should plot his meter on a time base as soon as taken. Should this curve depart greatly from a straight line, the probability is that something has gone wrong, and attempts should be made to locate it. In any case, by drawing the best average straight line through all the points, the average pounds of steam per hour throughout the trial is easily obtained. If either of the other methods be used, readings should be

Digitized by Google

taken every five or ten minutes. In calculating the final result the average of both these and the generator readings should be used.

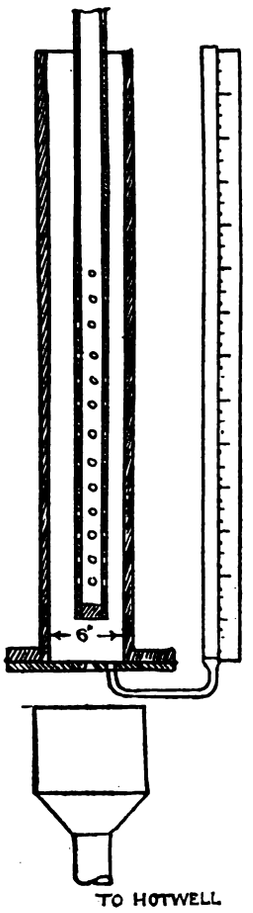

FIG. 7.

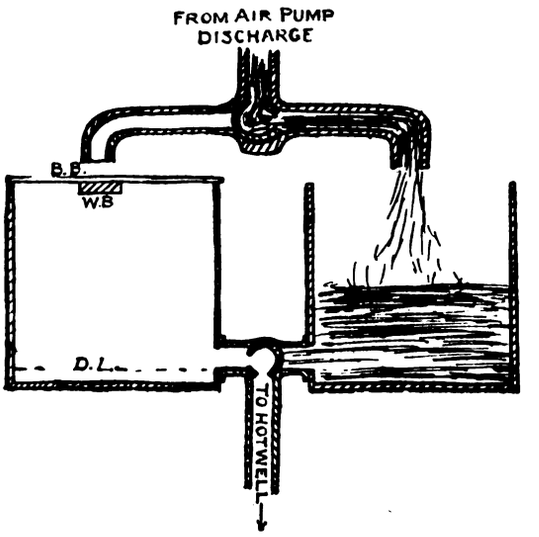
The best English work on the testing of engines and boilers is "Experimental Engineering—Vol. 1, Engines and Boilers," by Prof. W. W. F. Pullen, 654 pages, published by the Scientific Publishing Company at 15s. net.—B.Sc.

Answer to No. 821 (*awarded 7s. 6d.*).—The best way for "Electron" to make the desired test will be by attaching a special discharge pipe to the air-pump discharge of the condenser which is isolated on to the set under test, and by collecting the condensed steam in two calibrated tanks. Five hours will be long enough to give reliable results, the object of specifying eight-hour tests being that after six hours' running it has been found that the parts do not then increase in temperature under normal conditions; the last two hours are then used for taking overload and working to atmosphere tests. The sketch shows the arrangement of tanks, etc., for conducting the test. The pipe fitted with the two branches is from the air-pump discharge, and is fitted with a cock enabling it to deliver to either tank. Both tanks are connected to a common outlet pipe, which can be led away to the hot-well, or elsewhere, as desired, and which is also fitted with a cock to enable it to empty either tank. The two tanks are calibrated as follows: Fill up to the discharge level, D L, and then fill up with a 10-gallon measure (carefully noting the number used) until the water just touches the underside of the wooden block, W B. This block is attached to a thin flat batten, which can be laid across the top of the tank, and the block, W B, should be planed down until an exact number of gallons is registered between D L and W B. In getting the set ready for testing, go round all drains, trap discharges and drippings from rod and spindle glands, and see that they are all either led into the exhaust pipe or collected and measured; and if a grease separator is used in between engine exhaust and condenser, the water collected in the separator must also be measured, together with the steam used to pump it away from the separator. All connections should be made, if possible, the night before testing, and the alternator leads should be led away to the water resistance, and all necessary connections completed. A reliable ammeter and voltmeter, reading virtual amperes and volts, should be used, and a standard kilowatt-hour meter put in series with each phase. If the water resistance is out of sight of the place of testing, it is a good plan to signal by means of lamps, worked from switches at the testing place, a red lamp being lit up when the load is exceeding the correct load, and a white one when the load is dropping below the correct load. The set should be run up about half an hour previous to the test being taken; this will enable things to be well warmed up and a flying start to be made. If it is



desired to indicate the engine as well as to ascertain the water used per kilowatt-hour, the indicator gear should have been overhauled and three indicators be fixed—one on each cylinder—connected to a three-way cock communicating with the top and bottom ends of the cylinder as desired. A high-reading thermometer should be placed just before and a tested steam gauge just after the main engine stop valve. All glands should be gone round and *slacked* off as far as possible without blowing resulting. A reliable tachometer and a revolution counter should also be used on the engine and alternator shaft. One person and one watch should be regarded as the standard through the test, and two reliable men should be stationed on the tanks. As soon as all is ready, the readings of the counter, kilowatt-hour meter, and barometer should be noted, and the temperature and pressure of the steam at the stop valve taken, and the load put on the engine, and at the next quarter of the clock take the first reading. The water is, of course, collected in the calibrated tanks as soon as the test is started, and each observer should independently mark down the number of tanks filled. As soon as one tank is full the cock must be thrown over and the other started to fill, the first being emptied at once and the discharge closed ready for the next time of filling up. The discharge pipe from the tanks should be much greater than the discharge pipe from the air-pump. The readings to be taken should be as follows: To be taken every half-hour, starting at the first quarter after test commences. Time to be noted of each reading.

Steam pressure at stop valve and degrees superheat.	Load as shown by ammeters and voltmeters.	Vacuum in inches.	Revolutions per minute.	Time of reading.

Also any remarks as to conditions.

In between each of these readings a set of cards should be taken, the three cards from the top ends to be taken simultaneously, and the three cards from the bottom ends of cylinder to be taken also simultaneously, and as soon after the top set as possible, the load being kept as absolutely constant as possible. On the back of the cards mark down the following: generating set number; cylinder (high pressure, intermediate pressure, low pressure, and which end); steam pressure at stop valve; degrees superheat; reading of voltmeters; reading of ammeters; revolutions per minute; pressure in each receiver; vacuum in inches; temperature of discharge water from air-pump; taken by (and time); piston stroke; piston diameter; piston rod diameter; percentage of clearance volume to

Digitized by Google

cylinder volume; scale of diagram; any remarks as to conditions thought necessary.

Of course, if "Electron" simply wishes to know the water used per kilowatt-hour, he can omit the indicating part of the test, but as it involves very little extra trouble, and will give a great deal of information of a valuable nature, it should not be omitted. The total number of revolutions made by the counter should be taken down and the tachometer checked against it. All that "Electron" wishes to know is: units generated, water used, and

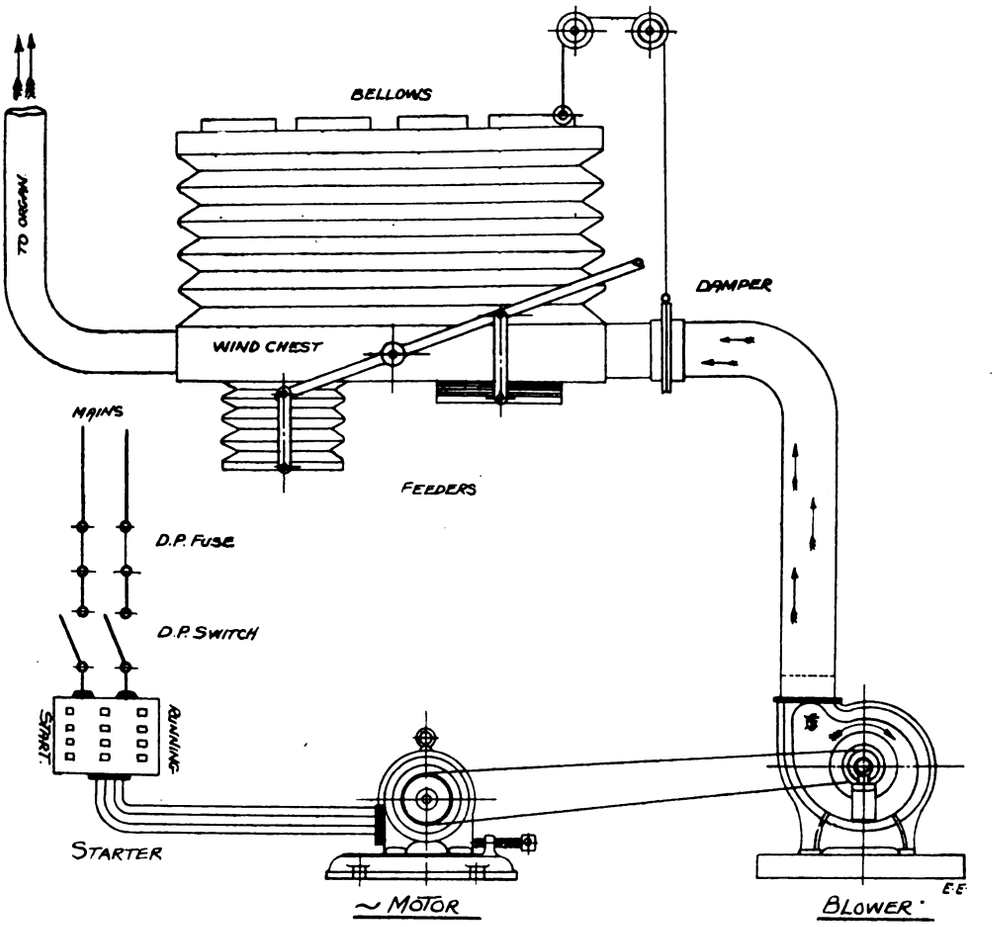
$$\frac{\text{Water used}}{\text{units generated}} = \text{water per kilowatt-hour.}$$

The writer has used the above methods in larger sets than 700 kw. with good results. The calibrating tanks, if of 130-140 gallons capacity, will be quite large enough.

A good book on the subject is "Indicator Diagrams and Engine Testing," by C. H. Day (4s. 6d.), published by the Technical Publishing Company, Deansgate, Manchester.—W. T. W.

of speed to keep a constant supply of air, and would not start with the load without the aid of a special friction clutch in connection with the worm gear. There still remain the extra cost of the reducing gear and the necessary motor-controlling switch. The best and most suitable way is to employ a centrifugal blower in the manner shown in the sketch, thus obviating the use of any special electrical controlling gear. The main advantages being ease of starting and entirely automatic wind control, also the motor and fan may be placed at any distance from the organ. The motor runs at constant speed, and in the case of a continuous or alternating supply there is no loss due to series regulating resistance.

The bellows are supplied with wind at a constant pressure by the fan, which is in turn driven by belt from the motor, the volume of air being automatically controlled by the sliding damper. The weight on the bellows causes depression when empty, and this movement raises the damper, allowing sufficient air to pass to fill them again, when the damper again closes. The motor may be left running for



Question No 822.—It is desired to work the bellows of a church organ by a single-phase motor. Describe the best way of doing this, and sketch the automatic starting and regulating switch. The motor would require to be of about 1 h.p.

Answer to No. 822 (*awarded* 7*s.* 6*d.*).—The application of electricity for working the bellows in connection with church organs is recognised as one of the cheapest and best methods if applied in the right manner. There are two or three methods of applying it, one being to have the motor driving a crankshaft (through reduction gear), on to which are connected at the various angles the connecting rods from the feeder bellows. This method resembles a two or three crank steam-engine, the feeders taking the place of the pistons. This is quite suitable where continuous or three-phase current is available, but with a single-phase supply it is more difficult.

It is generally known that a single-phase induction motor is not self-starting against any load, and is, moreover, very difficult to regulate for speed, a 10 per cent. or 20 per cent. variation being the maximum (except where a series-wound commutator repulsion motor is used).

These are the main disadvantages of this system, as the motor would have to be regulated over a large range any length of time without harm, and when the bellows are full a minimum of power is expended in driving the fan. The motor may be of the short-circuited rotor type, and started by means of a four-pole throw-over switch, which first puts into circuit the starting winding in series with a resistance. This starting coil is fixed on the stator, and causes sufficient phase displacement to start the motor. When nearly maximum speed is obtained the switch is thrown over to the running position, cutting out the starting winding entirely and putting the stator across the mains. As the output of this type of fan increases with the speed, no great load is put on the motor until maximum speed is obtained, and by that time the switch will be in the running position. The feeder bellows and hand gear need not be detached, and would be found useful should the electrical supply at any time fail. Care should be taken in choosing the driving belt, as this item in many cases creates a lot of noise. It should be of a very soft nature, either of raw hide or laminated leather, and made endless.—P. DEAN.

[Other replies to Question No. 822 will be given in our next issue.—ED. *E. E.*]

Questions may be sent at any time.

QUESTIONS.

841. When a conductor is charged with electricity, the whole charge resides on the surface of the conductor; when, however, the conductor is carrying a current, the whole cross-section of the material is in use. How can these two commonly accepted facts be reconciled?—SUPERHEAT.

ANSWERS.

Question No. 822.—It is desired to work the bellows of a church organ by a single-phase motor. Describe the best way of doing this, and sketch the automatic starting and regulating switch. The motor would require to be of about 1 h.p.

Answer to No. 822 (*awarded* 7*s.* 6*d.*).—Electricity affords the best and most suitable means of driving bellows to furnish wind for organs. There are objections to all other mechanical systems which do not apply to electricity. The gas or oil is noisy; the steam-engine requires constant attention; the water motor cannot be depended upon to provide a regular supply of wind, and in frosty weather the pipes are liable to freeze. Electricity, properly applied, contains none of these objections. The electric motor remains unaffected by changes of temperature, requires no attendant, occupies small space, and is quiet in action.

There are one or two things to be taken into consideration in answering this question: (1) For variable-speed work, where constant stopping and starting are required, the single-phase motor with short-circuited rotor is not so readily adaptable for this class of work as is the shunt-wound direct-current motor. (2) There is difficulty inherent with single-phase motors in starting under load, so that if wind-chest or reservoir is to be supplied by feeder bellows from a crankshaft, this will have to be specially arranged with fast and loose pulleys, which can be worked automatically from air reservoir by chains or ropes. (3) The argument in favour of the single-phase motor of this type is its simplicity and the absence of wearing parts.

Fig. 1 shows an arrangement which should work very well. The various parts are shown diagrammatically, and the various positions are suggestive only. "J. A. M." will be able to follow the outlines of the scheme from the sketch and the following explanation: A is wind-chest; B and C are two feeders connected to crankshaft, to the end of which is fitted a fast cone pulley, D, also a loose pulley, G. A corresponding cone pulley, E, is fitted to countershaft, C S F F are fast and loose pulleys, with a hand arrangement, H^1, for putting the belt on to the fast pulley after the motor is started. This could be arranged to work from the keyboard. When commencing the play, the organist starts the motors in the usual way, with belt on loose pulley, pulling belt on to fast pulley when motor is up to full speed. As the wind-chest will probably be empty, the belt will be on thick side of cone pulley, E, and *vice versâ* on D. The wind-chest will begin to expand, the ropes connected to wind-chest at

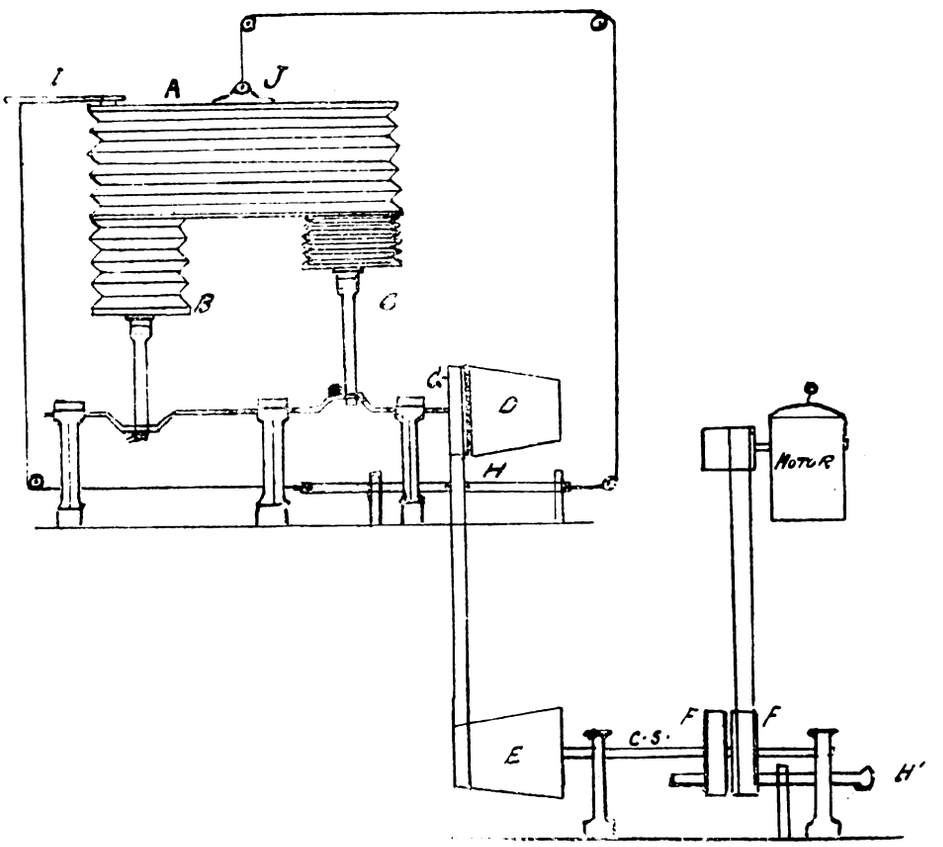

FIG. 1.

I and J and rod, H, will draw the belt to thick side of cone pulley, D, and finally on to loose pulley, G, stopping the feeders, B and C. The wind-chest will now slowly collapse, drawing belt on to slow speed of cone pulley, D. This arrangement will regulate the speed of feeders,

Digitized by Google

B and C, in accordance with the demand for wind. A little more than 1 h.p. will be required for this. Now I should advise the putting down of a combined set of motor and centrifugal blower, feeding direct into wind-chest, A, the feeders, B and C, being left for hand blowing in case of accident or stoppage to motor. The motor in this case, as in above, will run at constant speed, the pressure from blower, which is regulated by S V, being just sufficient to keep reservoir always full. E V is over switch, M motor, B blower. F is a flexible connection to wind-pipe to prevent noise from motor and blower being heard at keyboard.—C. W. HOLMAN.

Answer to No. 822 (*awarded* 5*s.*).—This query comprises two sections—viz: (1) the transmission of power from the shaft of the motor (running at a comparatively high speed) to the organ lever moving at, say, 35 complete (one up and one down) strokes per minute; (2) the automatic control of the driving power, and consequently the amount

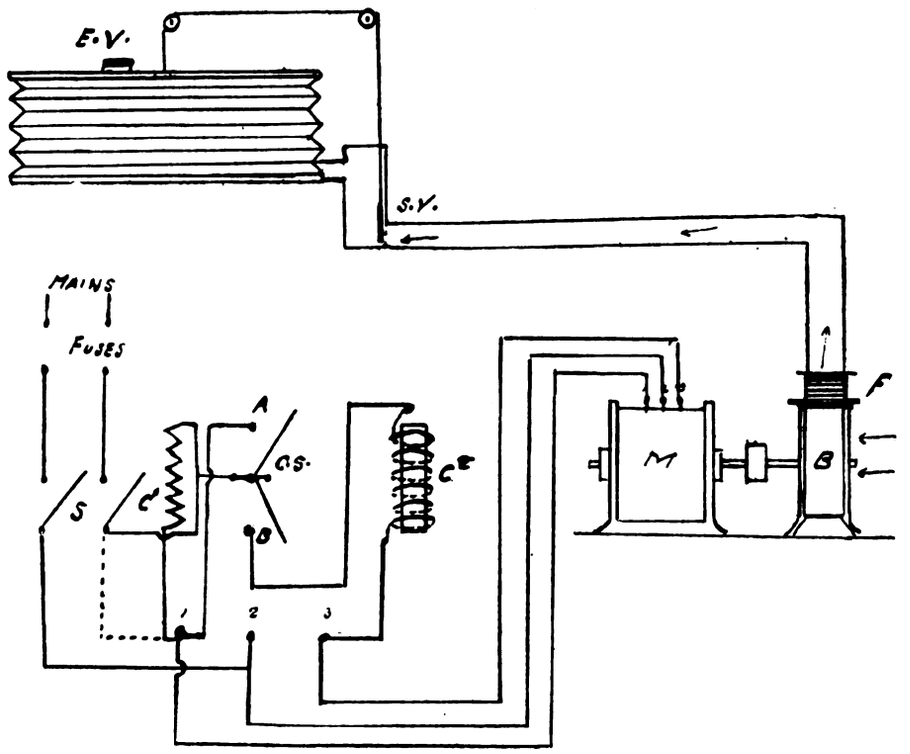

FIG. 2.

an escape valve. The author has known this to give better satisfaction with continuous-current motors than the variable-speed controlling arrangements, which give constant annoyance through burning of contacts and regulating resistance.

Fig. 2 shows this arrangement with starting switch connections for motor in both cases. The stator is provided with an auxiliary winding in parallel with the main winding. In series with the former (while the motor is being started) is inserted an inductive resistance, C^2, whilst

of air to be supplied according to the requirements of the player. The first section does not require a deal of explanation. Without doubt the best way to drive is by means of worm gearing. By this means a speed of 35 r.p.m. can easily be obtained on the worm-wheel shaft with the motor running at, say, 1,450 r.p.m., which is the usual figure for a 1-h.p machine on a 50 cycle circuit. The worm-wheel shaft must be provided with a crank, and will drive as shown in Fig. 1. Of course, if the circumstances of the case permit, the speed reduction could be obtained

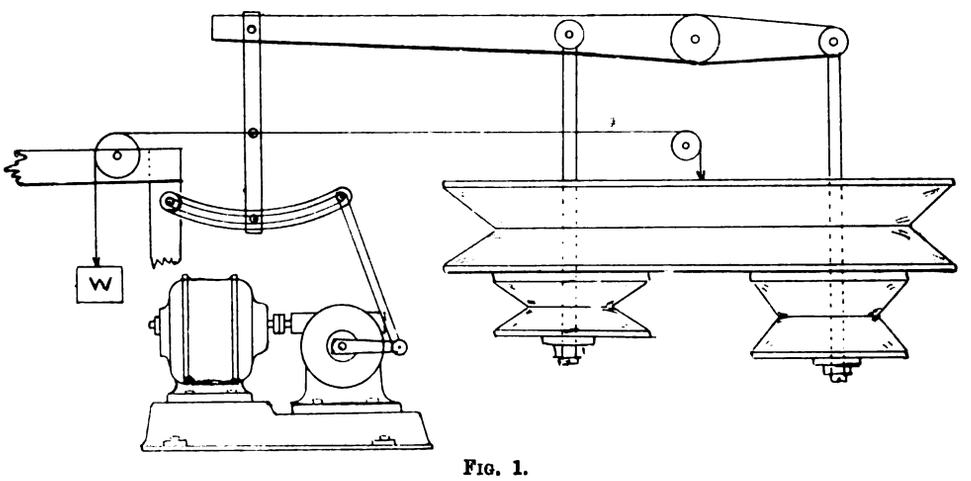

FIG. 1.

the main circuit is placed in series with a non-inductive resistance, the result being that a difference in phase occurs between the two circuits, thus producing a rotating field. As soon as the rotor has attained its maximum speed the auxiliary circuit is opened, and the non-inductive resistance short-circuited. The machine then continues to run as a single-phase synchronous motor. S is double-pole main switch, B is the starting position, A is the running position, C^1 non-inductive resistance, C^2 choking coil, C S change

by means of spur gearing (which would probably have to be double) or by countershafts and pulleys, and perhaps by a combination of both. With such an arrangement, however, there would be the risk of noise, and this is quite inadmissible unless the motor and gear could be placed in an adjoining room or basement away from the organ chamber. Another way of adapting an electric motor for organ blowing is to dispense with the ordinary lever handle and feeders, and deliver air direct into the reservoir

Digitized by Google

from a centrifugal fan. Such a motor-driven fan can be constructed to work quite silently, and, as will be seen from the remarks under the next section, the question of control is much simplified. This method of working is being used very successfully in the case of many large organs.

Coming now to the next section—viz., the method of controlling the amount of wind to be supplied—this can be accomplished in two or three ways. Firstly, the motor (which for the purpose should be of the wound rotor type with slip-rings) can be controlled by the insertion of resistance in the rotor windings. For this purpose, special starting and regulating resistances will have to be provided, and Fig. 2 shows how the apparatus would be arranged. In starting up, the double-pole main switch is first closed and the starting resistance moved round slowly in the usual manner. The motor then runs up to speed, and the starting coils are cut out of circuit by means of the auxiliary switch, *y*, as shown. All this time the regulating switch operated by the reservoir remains in the top position with no resistance in circuit, but as soon as the reservoir has risen a certain amount, the bar carrying the contacts on the regulating resistance begins to move downwards, thereby inserting resistance in the rotor circuit and reducing the speed of the motor. With an ordinary single-phase induction motor the speed could not be reduced by more than 40 per cent. without risk of the machine falling out of step and coming to a standstill, but with a repulsion or reactance motor the necessary speed regulation could be obtained satisfactorily. For this arrangement it will, of course, be necessary to have a motor starting with considerable torque, of which there are now several on the market.

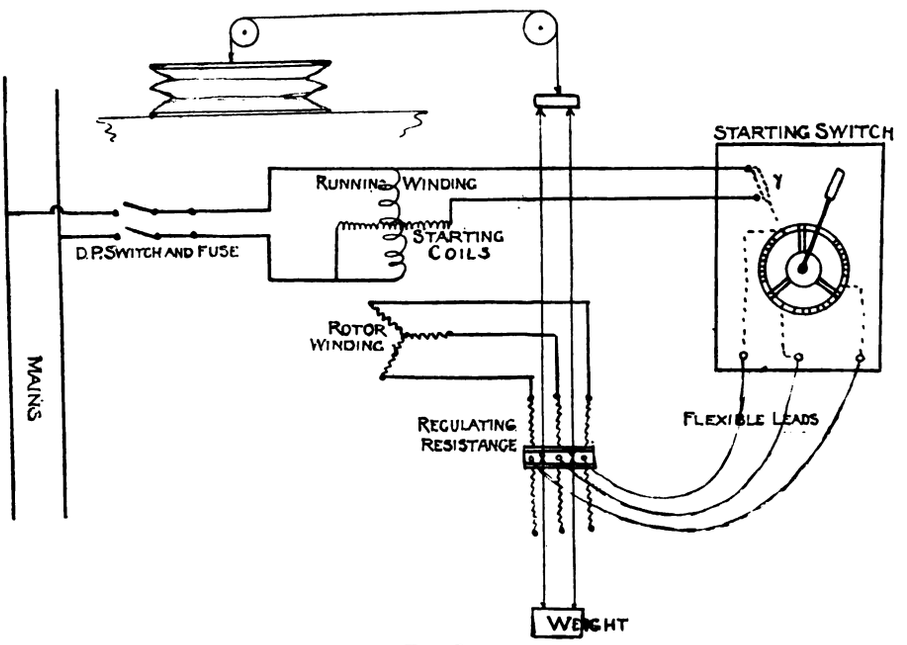

FIG. 2.

Another method of arranging matters is shown in Fig. 1 Here the motor and gear drive on to a quadrant, which in turn is connected to the organ lever as shown. By means of the weight, W, and the flexible cord attached to the reservoir, the position of the rod connecting quadrant and organ lever is adjusted automatically at the lower end, so that the length of stroke, and consequently amount of air supplied by feeders, depends upon the position of the reservoir. In practice the parts will adjust themselves to the needs of the wind supply, and when no or very little wind is required the stroke should be quite small, and the motor will be running practically light under these conditions. With such an arrangement the ordinary starting switch and resistance will be quite good enough, but the motor will have to be capable of starting with load. If a very cheap installation is wanted and the organ not used much, so that efficiency does not count, then the motor could be arranged to work always at practically full load with no automatic gear whatever. The excess of air would be allowed to escape by a valve worked from the reservoir in a similar way to the ordinary over-blowing valve. This is not so uneconomical as it would seem at first sight, because the power required from the motor is considerably less than the full-load power when the organ reservoir is over-blowing. The motor would, of course, be stopped when the wind is not actually required.

In connection with the fan blowing arrangement mentioned above the control is very simple. All that is necessary is a valve between the blower (preferably by the fan) and the reservoir, this valve being arranged to open when the reservoir falls and close when the reservoir reaches its full capacity. With this blower arranged in such a way the consumption of energy is proportional to the work done. When the organ is at rest the motor runs practically light, and when a little wind is required the current consumption of the motor increases. With the maximum wind supply the motor would be running under full load.

A further advantage of the motor-driven blower is that the motor can start quite light (there being practically no load until the fan attains at least half speed) thereby enabling a cheaper motor to be used, while the starting switchgear can be quite simple, and, if necessary, could be conveniently arranged near the organ keyboard.—P. W. F.

Answer to No. 822 (*awarded* 5*s.*).—The best type of single-phase induction motor for the purpose specified will be one having an auxiliary stator winding. This winding

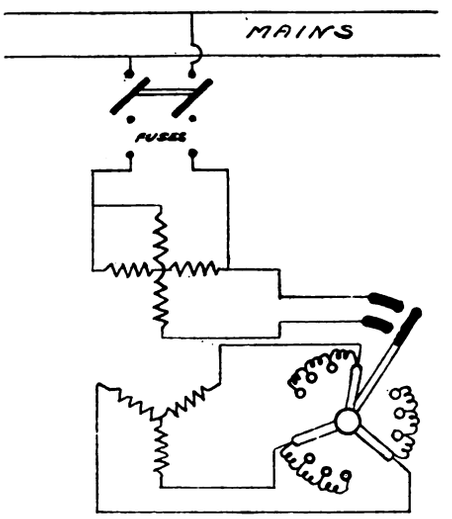

FIG. 1

is only used while starting, being cut out when the motor has attained its full speed. Fig. 1 is a diagrammatic sketch of the connections of such a motor. It will be seen that the starting switch, after short-circuiting the rotor resist-

Digitized by Google

ances, cuts out the auxiliary winding by means of the long arm, leaving the running winding only across the mains. The current can be completely cut off the motor by means of the double-pole switch, but before starting the starting switch must be turned so that all the resistance is in rotor circuits and the auxiliary winding joined up in parallel with the running winding. Such a motor will give difficulty with regard to starting and speed regulation; to get over this the writer suggests an arrangement as shown in Fig. 2. The motor when started is kept running at full speed; a worm on the rotor spindle engages with a worm-wheel which runs loose on the main shaft.

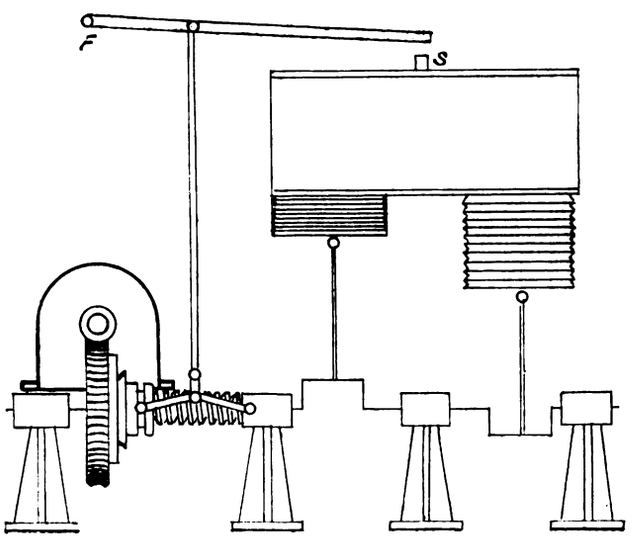

FIG. 2.

This worm-wheel has a recess, in which fits a coned friction clutch; the clutch works freely on the main shaft, and turns with it by means of a "feather." Between the clutch and the bearing is a helical spring, which, when the bellows are working, presses the clutch firmly against the worm-wheel. When bellows are full, the stop, S, engages with lever working round the fulcrum, F. This lifts the links and draws back the friction clutch against the action of the spring. Motor then simply drives the worm-wheel. In the sketch only two links are shown, but there are also two on the other side. This is arranged so that they do not interfere with the spring, and the pull on the clutch is well distributed when being withdrawn. The upward motion of the lever closes the spring and frees the friction clutch. The reduction by means of worm and wheel should give a speed of from 20 to 30 per minute. Belting has not been suggested, as belts are often troublesome on account of their noise. A 1-h.p. motor will only be suitable for driving the bellows of a comparatively small church organ. More power is required for this purpose than is generally supposed.—M. M.

Question No. 823.—In a station with which I am connected there is installed a turbo-generator with compensating coils in series, with the armature wound in slots in the pole faces. The object of these coils is to enable the machine to commute sparklessly with a fixed position of the brushes at all loads. Will someone please explain exactly how this is effected?

Answer to No. 823 (*awarded* 7*s.* 6*d.*).—A few remarks on the theory of sparkless commutation will not be out of place before we explain the action of the compensating coils. Fig. 1 represents diagrammatically the armature coils, the commutator segments, and a brush. In the position shown, no current passes in the short-circuited coil, A, but when the commutator moves in the direction of the arrow, the brush will come out of contact with segment B. Now, the self-induction of coil A (the ohmic resistance also, but in a small measure) will oppose a resistance to the passage of the current, and sparking will occur between brush and segment B. This is what happens when coil A is in the neutral zone, so that no E.M.F. can be induced into it by rotation. Now, if we displace the brushes in the direction of rotation, the coils short-circuited by the brushes will be in a field of a certain strength, and an E.M.F. will be induced in them by rotation. This E.M.F. opposes the E.M.F. of self-induction, so that the resistance offered by coil A to the passage of the current when the brush leaves segment B will be reduced and the sparking as well.

Now let us examine the effect of the armature reaction. Fig. 2 must be familiar to who have studied sparkless commutation. M C D N represents the field produced by the magnet, M E F N the field produced by the armature current, half of which is opposed to the main field and half of which assists it. The superposition of these two fields gives the resulting field, M G H N. Now, as the load increases, the armature reaction increases also, and, there-

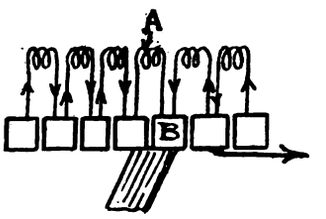

FIG 1.

fore, the distorting effect. The resulting field will be strengthened on the right-hand side and weakened on the left. We have seen that, in order to obtain sparkless commutation, the E.M.F. induced by rotation in the short-circuited armature coils must oppose the E.M.F. of self-induction, and that these coils must be placed in a field *sufficiently strong* These coils must also be in the weaker field on the left-hand side, so that any increase of load will increase the sparking.

Turning, now, to Fig. 3, we can explain the action of the compensating coils. The pole is fitted with two coils, R and T, which each embrace half the pole width. These coils are in series with the armature, but wound in opposite directions so as to produce a field somewhat like

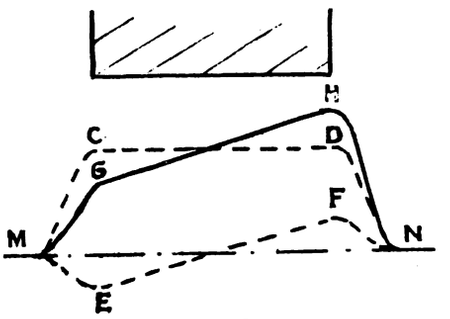

FIG. 2.

M K L N. This field will naturally increase with the load, just as the armature reaction which it opposes. In this way the total flux remains constant, and the weakening on the left-hand side (Fig. 2) is prevented. The coils can even be made to more than compensate the armature reaction so as to strengthen the field on the left-hand side

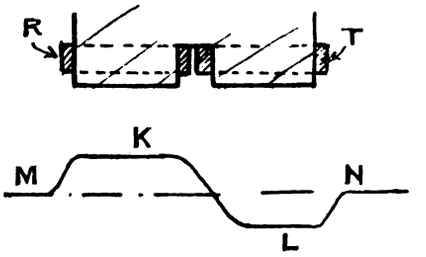

FIG. 3.

when the load increases. In this way the E.M.F. of self-induction, which increases with the load, will always be opposed by an E.M.F. induced by rotation, which increases in a similar way, so that the position of the brushes will be the same at all loads.—ALTERNATOR.

[Other replies to Question No 823 will be given in our next issue.—ED. *E. E.*]

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

830. A dynamo is to supply lamps and also charge a secondary 50-volt battery of six cells. When dynamo is not working, the battery will feed the lamps. Describe a "fool-proof" arrangement so that, whether dynamo or battery feeds the lamps, a V.M. and an A.M. should always remain in circuit. Also arrange that three or more cells may be thrown into the circuit as required.—K. C. N.

ANSWERS.

Question No. 823.—In a station with which I am connected there is installed a turbo-generator with compensating coils in series, with the armature wound in slots in the pole faces. The object of these coils is to enable the machine to commute sparklessly with a fixed position of the brushes at all loads. Will someone please explain exactly how this is effected?

Answer to No. 823 (*awarded 7s. 6d.*).—This question is purely one of armature reaction in dynamos and the means of overcoming it. The present practice invariably calls for dynamos and motors with fixed brush position at all loads without sparking, but until recently this was not the case, the brushes having to be moved with the load on the machine to prevent sparking. The increased sparking with rise of load is due to the interference of the magnetic field set up by the current flowing in the armature, the tendency of the latter being to produce a cross magnetisation through the armature core at right angles to the useful flux, resulting in a distortion of the main dynamo field in the air-gap.

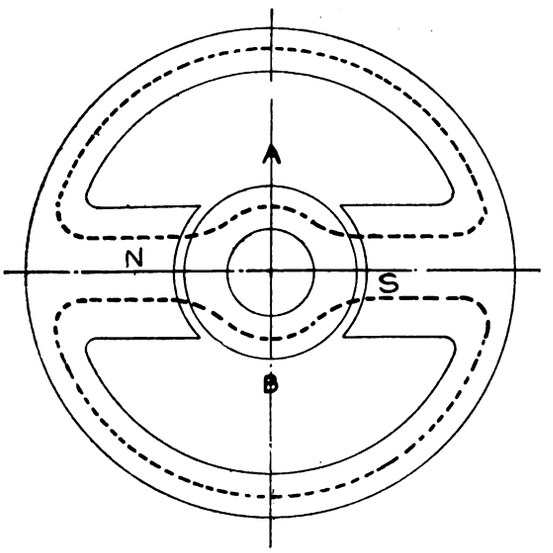

FIG. 1.

Fig. 1 shows the direction of the useful field from gap to gap when no current is flowing in the armature winding, the neutral line or diameter of commutation, A B, being perfectly vertical and midway between the pole corners. When a heavy current flows through the winding, the resultant cross flux so interferes with the main field as to completely shift it round in the direction of rotation in a generator, and against it in a motor. The result is a crowding of lines under the trailing pole corners and a falling off under the leading ones. With the shifting of the main field the neutral line will also have to be moved into a proper reversing field for commutation.

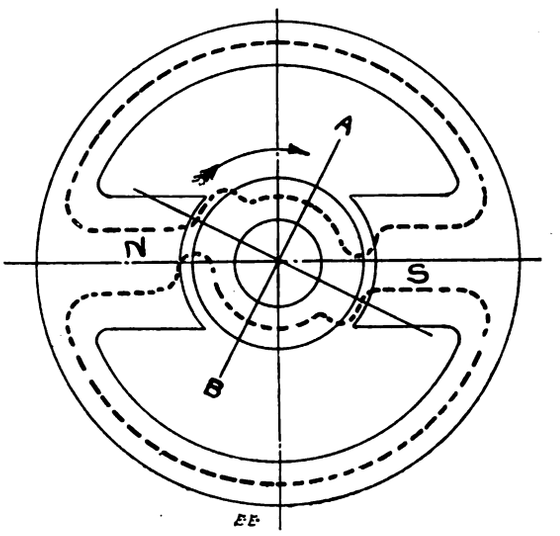

FIG. 2.

Fig. 2 shows the displacement of the flux when the armature is loaded. It is obvious from the above that to obtain a fixed brush position for all loads the armature distortion or reaction will have to be checked, or, better still, made a negligible amount in proportion to the main field. For sparkless collection, the armature ampere-turns per pole should not be more than 50 per cent. of the field-turns—namely, ampere-turns required to drive the flux through the gap and teeth. Under the leading pole-horn the density should not be allowed to fall below 13,000 lines per square inch. The main object to consider when designing a generator is to get a good stiff field in the gap which cannot be very easily shifted, and one or two ways of doing it is as follows: specially shaping the pole-shoes; boring the pole-faces eccentric to the armature, thus forming an air-gap of unequal length, the shortest distance being at the centre of pole, where the main field is strongest; using poles with slots cut in them running parallel with the axis of the armature, thus increasing the reluctance of the cross magnetisation path and preventing crowding at the corners. Balancing the cross magnetisation by means of special winding on the poles and compensating armature winding due to Sayers.

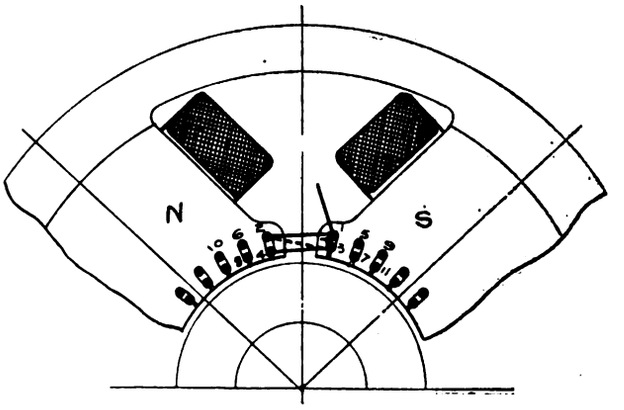

FIG. 3.

The method referred to in the question is apparently Ryan's method of balancing winding, as shown in Fig. 3. This consists of surrounding the armature with a stationary winding, exactly equal in its magnetising effects to the

Digitized by Google

armature, but directly opposed to the latter, thus balancing all armature reaction. A number of coils are wound in the manner shown into slots cut on the pole face, and connected in series with the armature; thus the same current will flow through both armature and field, and, as the number of turns are the same, the resultant flux will be equal, and the two magnetomotive forces, working in opposition, will balance and neutralise each other, leaving the main field and neutral line unaltered. It may be added that the above method of obtaining sparkless commutation is seldom used, the present tendency being to design the machine with a low reactance voltage and depend upon an auxiliary magnet placed between the poles to provide the necessary reversing field for commutation.—P. DEAN.

Answer to No. 823 (*awarded* 7*s.* 6*d.*).—It is well known that in a continuous-current generator there is a field induced by the current flowing through the armature which is superposed on the main exciting field, the result being that the latter is distorted by the former. In the case of a generator the net result is that the resultant field is shifted slightly round in the direction of rotation of the armature—*i.e*, the leading pole-tips are weakened and the trailing tips are strengthened. Now, in order to commutate satisfactorily, it is necessary for the coil which is undergoing this operation to be just entering a field of opposite polarity to that which it is leaving, so that there may be induced in it an E.M.F. in the opposite direction of such a magnitude that, during the time it is short-circuited under the brush, it may make the original current flowing therein die down and a new current of the same magnitude but opposite direction grow up. This reversing field is that due to the leading pole-tips. The current through the armature is proportional to the load, and hence the distortion of the field due to the armature reaction is also proportional to the load, and so the leading pole-tips under which commutation takes place are weakened more or more as the load on the machine rises. In order to have the coil in a sufficiently strong field to reverse the current in it, it is necessary to move the brushes forward as the load on the machine rises. This brings up one or two other matters, such as the demagnetising effect of the armature on the field, etc., but it is hardly necessary to touch on these in this answer. Fig. 1 explains this armature reaction

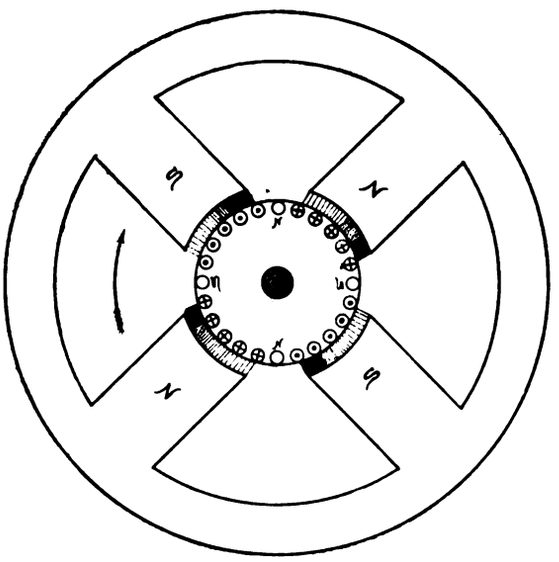

FIG. 1.

For the purpose of overcoming this necessity for moving the brushes forward several devices may be adopted, one of which is by using these compensating coils wound through the poles of the field magnet. All the current from the machine passes through these, or else a fixed percentage of it, and, therefore, the field induced by them is also proportional to the load on the machine. They are connected up so as to counteract the armature flux, which, it will be seen, is at right angles to the field-magnet flux, and hence their flux is also at right angles to the main flux. By suitably designing these coils, their flux may be made exactly equal to the armature flux, and, being opposite it in direction, may be made to completely wipe this out. If this be done, it will be seen that the main flux will not be distorted by the currents flowing in the armature, and hence it will not be necessary to rock the brushes forward, whatever the load be. Also, it may be adjusted so that the flux due to the compensating windings be slightly in excess of that due to the armature ampere-turns, resulting in a slight increase of flux through the *leading* pole-tip, which will still further assist commutation. The important point to note is that

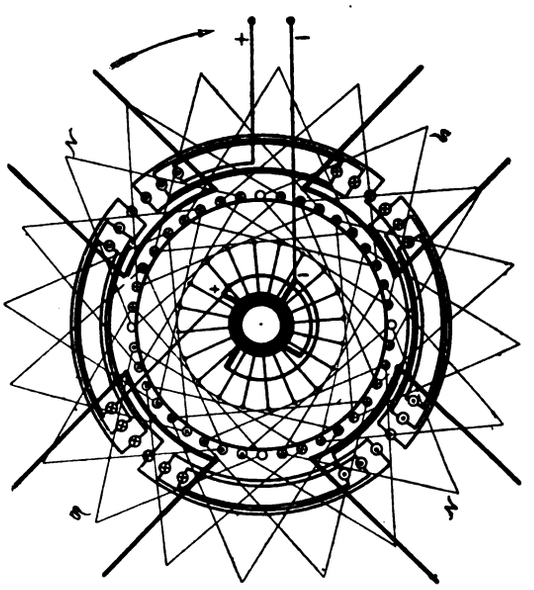

FIG. 2.

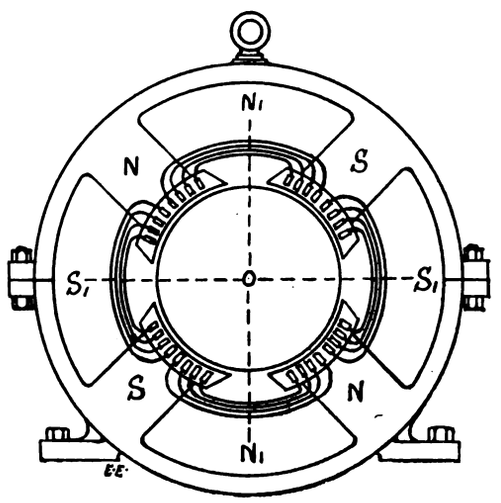
the compensating ampere-turns must be equal or slightly in excess of the armature ampere-turns. Fig. 2 explains this, and though at first sight a little complicated, is really not so. I have shown a four-pole machine, and we are supposed to be looking at the commutator end of it. The small circles represent slots in the armature and poles, those with a small black circle in indicate that the current in those wires is coming towards the observer, and those with a cross that the current is flowing down. The connections at the commutator end are shown as straight lines from one wire to another, and those at the back end are shown by the lines drawn outwards. It will be seen that all the current from the + brushes goes through slots in the poles forming the compensating winding all in series, and thence to the external circuit, returning direct to the − brushes. The above shows the type of winding adopted for a turbo-generator which the writer saw under construction.—E. R. ALEXANDER.

Answer to No. 823 (*awarded* 5*s.*).—Before explaining the effect of the compensating coils it will be better to explain, first, the reason why the brushes have to be shifted to obtain sparkless commutation when there are no compensating coils used. When the armature of the generator is caused to rotate, and the current traverses the coils of the armature, the field, due to the field magnets, becomes distorted. This distortion is due to the fact that the armature itself becomes a powerful electromagnet with distinct poles, having lines of force which do not coincide with those of the field magnets. The armature core is magnetised by the currents passing round it in such a manner that poles are produced midway between the poles of the field magnets, and in the accompanying diagram the direction of the lines of force due to the armature magnetisation is represented by O N_1 and O S_1. The actual field in the armature is, therefore, the resultant of these two fields both in magnitude and direction, and when the armature current varies, the component of the field due to the armature magnetisation likewise varies preportionately, so that the resultant field varies in direction, and to obtain sparkless commutation the brushes have to be shifted accordingly.

Now, to avoid this distortion of the field, the compensating coils, connected in series with the armature, are so

Digitized by Google

placed that their axes coincide with the axes of the poles produced by the armature magnetisation—that is, midway between the field-magnet poles. The number of turns of these coils is calculated so that, for a given current through the armature, the strength of field produced by them is equal to that produced by the armature coils; but being arranged so that the direction of the field produced by them is opposite to that of the armature magnetisation, the distorting effect of the armature current is completely counterbalanced. Whatever variation there is in the armature magnetisation, due to any variation in the load



on the generator, the field produced by the compensating coils always varies proportionately, and thus sparkless commutation is produced at all loads with the brushes in one fixed position.—POM.

Question No. 824.—What modifications, if any, may be made in the design of the *mechanical* parts of a rotary converter in comparison with a motor-generator of the same capacity?

Best Answer to No. 824 (*awarded* 10*s.*).—A motor-generator consists of a motor and a generator having their shafts coupled together. The motor has to develop all the power that the generator delivers plus the losses of the two machines. All this power, except the motor losses, has to be transmitted through the shaft to the generator. Hence we see that the armature spiders and shaft must be strong enough to transmit the full power to either machine. In a rotary converter, however, the power never leaves the surface of the armature, and the only torque the shaft is subject to is that due the friction losses. If this were the only factor affecting the size of shaft, a rotary converter would only require a very small one, but in designing a

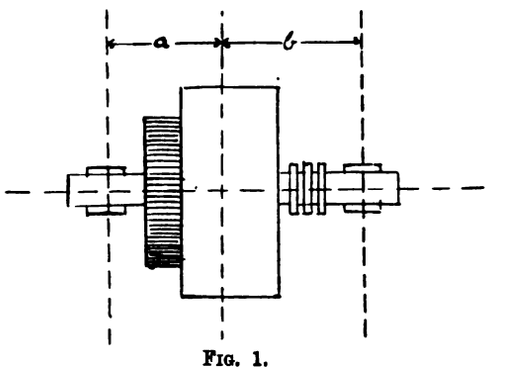


FIG. 1.

shaft we must consider the bending moment it is subject to as well as the twisting moment.

Let T_e = equivalent twisting moment;
T = torque transmitted;
M = maximum bending moment;

then $$T_e = M + \sqrt{M^2 + T^2}.$$

Now, it is the equivalent twisting moment which determines the size of shaft required. Thus we see that although the torque to be transmitted by a rotary converter is practically negligible, yet we may require a good big shaft to withstand the bending moment it is subject to. Now, the bending moment on a rotary converter shaft is necessarily greater than that on a motor-generator, whose direct-current armature is the same weight as the converter's one, owing to the fact that distance between the bearings is greater, for, as well as having a commutator on one side of the armature, it must have slip-rings on the other side.

Reverting to Fig. 1, let W = weight of the rotating parts, and a and b be the distances of their centroid from the two bearings. Then the bending moment on the shaft = $W \frac{a\,b}{a+b}$. In the motor-generator the maximum bending moment is on the direct-current side, as the

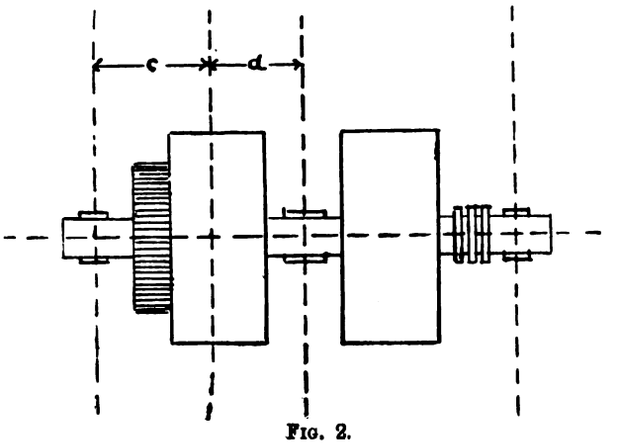

FIG. 2.

rotating part there is heavier and the distance between the bearings greater owing to the commutator. Hence, referring to Fig. 2, and using the same notation, we get the maximum bending moment on the motor-generator shaft = $W_1 \frac{c\,d}{c+d}$. Now $c = a$, and d is less than b; hence, if $W = W_1$, the maximum moment on the motor-generator shaft is less than that on the rotary converter. In most modern machines the ratio of the diameter of shaft in a motor-generator to that of a rotary converter of the same output is about 3 : 2. This alteration in the shaft and lightening the armature spider are the only mechanical modifications which can be introduced in the design of a rotary converter as compared with a motor-generator.

There is another type of motor-generator in which both windings are carried on one armature, but owing chiefly to insulation difficulties this type of machine is never made now, and does not require to be considered.—R. H. G.

Answer to No. 824 (*awarded* 5*s.*).—The greatest difference in construction is owing to the fact that, while the motor generator requires two, the rotary converter has only one magnetic system. The rotary is then the lighter and more compact of the two for any given output. The motor-generator really consists of two separate machines, either having the rotating parts on one common spindle or with their spindles mechanically connected together so that they revolve in unison. Generally, the two magnetic systems are mounted on one bed-plate provided with a third bearing between the direct and alternating current sides. This arrangement forms a long and more or less cumbersome combination. In order to do away with the middle bearing, some makers place the two systems close together on one bed-plate, and by fitting a very stiff spindle employ two bearings only. This makes a decidedly more compact machine, but it is questionable whether anything is saved in mechanical friction, and the combination is hardly so get-at-able from an attendant's point of view. There are two types of motor-generator to be considered—namely, synchronous and asynchronous. If the alternating (or motor) side is to run as an inductfon or asynchronous motor, there must be less clearance than if intended for synchronous running; therefore, it will be safer to have three bearings, in order that there shall be little danger of the spindle "whipping." The rotary converter with its one magnetic system is practically a direct-current dynamo with tappings from the armature winding brought out to slip-rings. In either rotary con-

Digitized by Google

verter or motor-generator it will be noticed that both commutator and slip-rings are required, but as the rotary has only one armature—or, perhaps, we had better say rotor—two bearings suffice. When a rotary is driven from the alternating-current side as a synchronous motor, there is not so great a necessity to reduce the air-gap. The small clearance that is required for the satisfactory running of induction machinery demands consideration from a mechanical standpoint; the design must be good and the workmanship excellent. With regard to the brush gear, in each case this will be much the same, but with a motor-generator having three bearings the designer will not be so much inclined to contract the commutator and slip-rings as he might be in the case of a similar machine fitted with two bearings only, or even with a rotary converter. Every designer is well aware of the danger attending any increase in the distance between bearings. Although the form of driving in both rotary and motor-generator is ideal, care should be taken to fit "ring-oilers" to the bearings; in any machine having more than two bearings, these bearings must be absolutely in line. In the case of a motor-generator, there should be a slide rail under the bed-plate below each magnet system. The general lines to be observed in machine design are always governed by the cost—the almighty dollar is a most potent factor. We are never in a position to criticise any piece of machinery without knowing at what price it was designed. Broadly, for either machine have the base ample and the centre of gravity as low as possible, large diameter of spindle with long bearings, and the space between bearings as small as allowable. Generally, the higher the speed the greater the output for a given amount of material, and the higher the efficiency.—M. M.

Answer to No. 824 (*awarded* 5s.).—In comparing the mechanical design of a continuous-current motor-generator with that of a rotary converter of the same capacity and speed, practically no modifications of the empirical rules governing the design may be made. Of course, if the speed is altered the diameter of the shafts will also differ. It is assumed that the motor-generator consists of a separate dynamo and motor coupled together and mounted on a common bed, the same arrangement being used for the rotary converter. Generally, the latter is used for transforming high-tension alternating current down to 500 volts or thereabouts continuous, but if transforming in the reverse direction—that is, the alternating-current side acting as the dynamo—provision must be made for the small dynamo used for excitation. This may be driven by belt from the converter or mounted on the extended shaft,

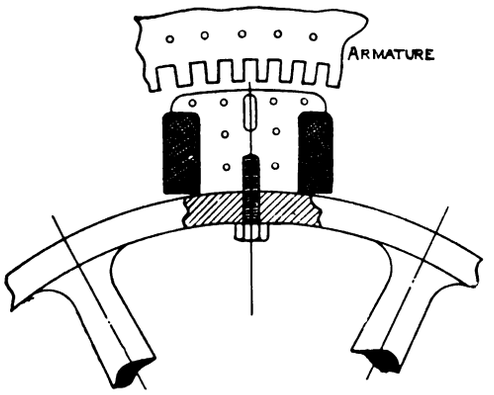

FIG 1.

a bracket being bolted on to the outer bearing to carry the field frame. The design of the field and armature system will, of course, be altered on the high-tension side, depending on the type of machine used. Should it be the revolving field type, in place of the armature core will be the magnet wheel, securely keyed to the shaft, the rim acting as the magnetic yoke. On to this will be mounted the magnet cores.

The method of constructing and mounting these differs with many makers, some bolting the complete laminated pole on to the yoke by means of bolts from the inner periphery of rim (Fig. 1), others making the yoke and pole-pieces entirely laminated, and fixed in the manner shown in Fig. 2. The armature in this case will be stationary and the core composed of laminations, slotted and built up in segments and bolted to a cast-iron shell.

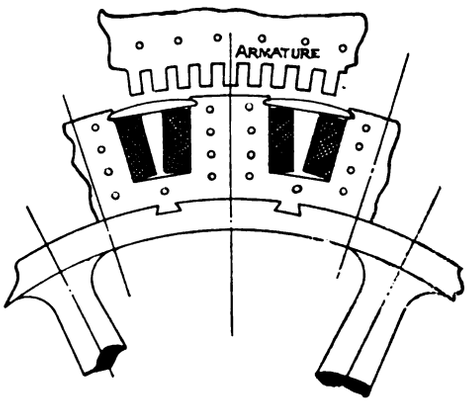

FIG. 2.

In either type of machine slip-rings will be used, and Fig. 3 shows a method of mounting them on the shaft, the brush arms being spaced at various angles and carried in the manner shown. The cables leading from the winding can be fastened to the flywheel arms and terminate in sweating sockets bolted to lugs cast on the inner periphery of the rings. The rings may be mounted on to an extended shaft outside the bearing, if necessary, and completely

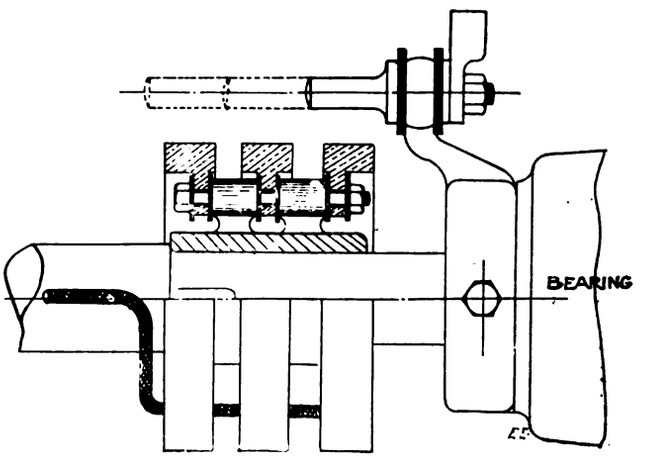

FIG. 3.

enclosed, the cables from the coils being brought through the shaft and out at the end. The latter method is generally used where the alternating-current machine is the motor, and short-circuiting devices are used to connect all the rings together and lift the brushes when the machine is up to speed. It may be mentioned that three bearings only are necessary, the centre one being close up the coupling. The coupling may be either solid or flexible, depending on the fluctuations in load and the alignment of the shafts.—P. DEAN.

Electrical Conductivities of Salt Solutions.—The *Proceedings* of the Chemical Society recently issued contains an abstract of a paper on "The Electrical Conductivities of some Salt Solutions in Acetamide," prepared under the joint authorship of Mr. James W. Walker and Mr. Frederick M. G. Johnson. The salts examined were mercuric chloride, potassium chloride, iodide, and cyanide. Of these the first is the only normal electrolyte, the others showing a maximum of molecular conductivity at about 30 or 40 litres, which then falls to about half value on dilution. Mercuric chloride is known to give a compound with acetamide, and potassium iodide is found to yield the compound $K1,6CH_3{\cdot}CO{\cdot}NH_2$. The migration ratio of the iodion is found to be greater than in aqueous solution, a fact which points to combination of ions with the solvent.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

831. A low-tension alternating-current distributing system is fed by two transformers in parallel. If after one transformer has been idle for a time (disconnected from both high-tension and low-tension 'bus bars) its secondary (low tension) is switched in, a *kick* is noticed on the ammeter of the other. Why is this?—H. R.

832. In a 200-kw. triple-expansion Belliss type engine running at 365 revolutions and taking saturated steam at 180lb. per square inch there is considerable vibration and knocking, although all bearings are reasonably tight. Indicator cards show that there is hardly any compression or cushioning effect in any of the cylinders at the end of the stroke. It is desired to know: (1) what are the causes and effects of this absence of compression; (2) how it may best be remedied?—B. S.

ANSWERS.

Question No. 825.—Is it necessary to have a complete circuit in order to have a flow of electric current? I have noticed that you can have shocks to earth off either the positive or negative rails of a certain electric railway, *both* rails being insulated. Is this due to defective insulation, or is it due to the fact that there is a difference of potential between *either* rail and earth?

Best Answer to No. 825 (*awarded* 10*s.*).—The fact of it being possible to receive shocks from either rail to earth is due to both conditions mentioned by "Wattman," for in order to obtain a shock there must be a difference of potential between the rail touched and earth, and the insulation of the other live rail must be defective in order to allow a flow of current through the body. It follows that, in the particular case mentioned, the insulation of both rails is defective. It is necessary to have a complete circuit for a flow of current, the circuit in this instance, assuming the + rail is touched, being as follows: From + brush of dynamo through cables and + rail to body, and through body to earth, from earth through various leakage paths, such as dirty or defective insulators, to − rail, thence through cables and − brush of dynamo and armature to + brush, completing the circuit. If the − rail is touched, the current flows from earth through body to − rail, the rest of the circuit remaining unaltered. (Of course, it is understood that + and − signs are merely conventions, and as such serve their purpose; we have no proof that current flows even, but it must be assumed that "Wattman" will be satisfied with these conventions, otherwise the first part of the question is equivalent to "What is electricity?").

The body of the man in contact simply forms an additional leakage path in parallel with the others. No shock can be experienced unless there is a complete circuit, as may be readily observed when handling live trolley wire from a tower wagon. On a fine day the wires may be handled with impunity, but on a wet day a nasty shock may be obtained due to the fact that in the latter case the insulation resistance of the wagon has been materially reduced by the wet on the woodwork, and sufficient current flows to earth through the body to cause a "shock."

When both rails are insulated, the potential of either rail in relation to earth, or the potential difference between either rail and earth, depends on the state of the insulation.

Let v = potential difference between rails;
V_1 = potential difference between one live rail and earth (1) (+ rail);
V_2 = potential difference between the other live rail and earth (2) (− rail);
f_1 = insulation resistance of (1) rail;
f_2 = insulation resistance of (2) rail.

Then $v = V_1 - V_2$; and $V_1 = v + V_2$; and $-V_2 = v - V_1$.

Current flowing to earth and from earth must be equal by law of conservation of energy, and by Kirchoff's law this is expressed in the following manner:

$$\frac{V_1}{f_1} = \frac{V_2}{f_2} = 0. \quad \therefore \frac{V_1}{f_1} = \frac{-V_2}{f_2} = \frac{v - V_1}{f_2}. \quad \therefore V_1 = \frac{v f_1}{(f_1 + f_2)}$$

and

$$\frac{V_2}{f_2} = \frac{v \div V_2}{f_1}. \quad \therefore V_2 = \frac{v f_2}{(f_1 + f_2)}.$$

The equations show that the potential difference between either rail and earth depends on the relative values of the insulation resistances of the rail. As an example, suppose the insulation resistance of the + rail to be three times as high as that of the − rail—*i.e.*, let $f_1 = 3 f_2$ and suppose line volts to be 500

$$V_1 = \frac{500 \times 3 f_2}{4 f_2} = 375$$

$$V_2 = \frac{500 \times f_2}{4 f_2} = -125$$

From this example it is easy to see that a shock could be obtained from either rail.

It may also be remarked that the potential differences on either rail fluctuate considerably, so that a rail which would be safe to touch one day might have a higher potential difference next day, owing to a fault developing on the other rail.—97.

Answer to No. 825 (*awarded* 5*s.*).—In electric railways there is always leakage current flowing from one rail to the other through earth, which varies according to the weather, being considerably greater in damp and foggy weather due to the insulators becoming coated with a thin film of moisture, producing surface leakage. The rails, insulators, and earth may be looked upon as condensers, a, b (Fig 1),

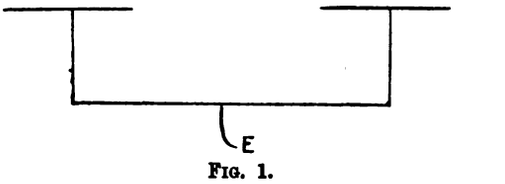

FIG. 1.

having a common earthed connection, E, of zero potential, A+ and B− representing the rails themselves, and the insulators of A and B serving as the dielectrics of the condensers, a and b respectively. For simplicity we shall suppose the insulation resistances between A and E and B and E are equal. Let the difference of potential between A and B = V. Then the voltage between A and E will be V/2, and the same between E and B. Suppose now that someone standing on earth touches A. Being (comparatively speaking) of fairly low resistance, he practically connects A to E through a conductor and receives a shock of V/2 volts due to the discharge of the condenser a, through his body. At the same time the rail A is brought to zero potential and B reduced to a potential of −V volts relative to the earth. No further shock would be experienced if the insulators had an infinite or very high resistance, but in practice the insulation resistance is sufficiently low to allow a current to

Digitized by Google

pass which would maintain a shock perceptible to most people, depending, of course, upon the value of V. If R is the resistance of the person in question and r_a r_b the insulation resistances to earth of A and B respectively, the condition of affairs may be represented in Fig. 2. The

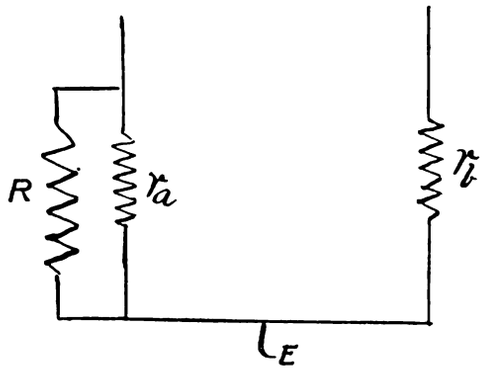

FIG. 2.

current will divide itself through the resistances according to Ohm's law, and he will experience a maintained shock of

$$V - r_b\left(\frac{V}{r_b + \frac{R + r_a}{R\, r_a}}\right) \text{ volts.}$$

If he now removes his hand from A, the latter will return to its original potential of V/2 volts relative to earth, and the first conditions will again hold on the assumption that $r_a = r_b$. It is evident that the same events will take place if he touches rail B. In some cases the maintained shock will be very much less than the shock obtained at the first touch. In cases where no shock is experienced off one line and a large one off the other, it must be assumed that the former is either dead earthed or has a very much lower insulation resistance than the latter.—R. D. A.

Answer to No. 825 (*awarded* 5*s.*).—In order that an electric current may flow, the essential conditions are that there must be a complete circuit, and that a difference of potential must exist between the points in the said circuit. If such a difference of potential exists between any two points, the value of the current which will flow between these points may be ascertained by the application of Ohm's law, which states that $C = \frac{E}{R}$, or the current in amperes is equal to the value obtained if the potential difference in volts is divided by the resistance in ohms, measured between the points under consideration. It should be mentioned that a complete circuit is not necessarily what is commonly known as a closed circuit, and need not be metallic throughout. For instance, two covered wires may only have a small insulation resistance, each to earth, and a leakage current may be caused to flow when a difference of potential is applied between the two wires. In this case, although apparently insulated from each other, there must be a complete circuit between the wires, and from these wires to the source of supply, for otherwise no current could flow. It should, however, be stated that, in order that all the leakage current may pass through the supposed insulating medium between these wires, the remainder of the circuit must be of high insulation, as otherwise a shunt circuit would be provided for the leakage current. It will thus be seen that, unless the insulation resistance of a circuit is high, a certain leakage of current will take place, and that this leakage increases as the potential difference in the circuit is increased, and as the insulation resistance is decreased.

In the question under consideration it is stated that shocks to earth may be obtained off both the positive and negative rails, and it will be clear from what has already been said that, although both rails are insulated, the shocks must be due to defective insulation on both poles. A little consideration will show that if contact is made with either rail, the body not being insulated from earth, and a shock is obtained, a current must flow through the body to earth. This current has to return to the other pole, since otherwise there would not be a complete circuit, and in order for it to do so the insulation of the other pole must be defective, and *vice versâ*. The insulation of both poles must, therefore, be more or less defective, and the amount of leakage current flowing will depend upon the potential difference and the total resistance through the earth between the poles. It will be seen that (neglecting the resistance of the earth itself to the flow of the current) since the potential difference of the supply exists between the ends of the earth circuit, there must be between the two rails and earth a sum potential difference equal to that of the supply, the two potential differences, as well as the shocks received from the two poles, being directly proportional to the insulation resistance of each of the latter to earth. The cause of the potential difference between either rail and earth is the defective insulation, and it should be pointed out that if the insulation of both poles were sound no potential difference would exist between either rail and earth, and it would be perfectly safe to touch either rail without fear of receiving a shock. Such a condition, however, is seldom met with in practice except with very low voltages, and a certain amount of leakage generally takes place except on the very smallest of systems.

In order to ascertain quickly the state of the insulation of a system, a useful test to apply is to insert between either pole and earth an incandescent lamp or batch of lamps in series requiring for full glow the same potential difference as that of the supply. The brilliancy of the light obtained will indicate the nature of the insulation resistance, full glow showing a bad earth on the opposite pole, and no glow showing good insulation on the opposite pole to which the lamps are connected.—H. A. N.

Answer to No. 825 (*awarded* 5*s.*).—It is necessary to have a complete circuit in order to have a flow of current. If direct current is being used, the whole of this circuit must be of conducting material. With alternating current, however, part of the circuit may be composed of non-conducting material or dielectric. A circuit containing a condenser is an example of this. In order to distinguish between the current flowing through a conductor and that flowing through a dielectric, it is usual to call the latter a "displacement current" and the former a "conduction current." It must be clearly understood that these names have reference only to the nature of the medium through which the current passes, and do not imply that there are two *kinds* of current.

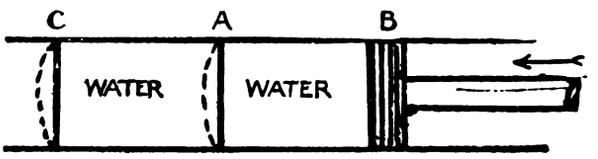

FIG. 1.

Some idea of the nature of a displacement current may be obtained from the consideration of the following hydraulic analogy. In Fig. 1, A B C represents a cylinder; B is a well-fitting piston; A and C are pieces of elastic membrane stretched across the cylinder. The space between A and B and A and C is quite filled with water. On applying pressure to B, in the direction shown by the arrow, the membrane, A, will bulge out as shown by the dotted line, since the space between B and A is entirely filled with water. Now, it is obvious that this bulging of A will cause a similar bulging out of C for the like reason. It is seen, then, that the yielding of A produced a slight flow of water towards C. In the electrical case, A and C would correspond to the insulator or dielectric between the plates of a condenser, while the water occupying the spaces between these would represent the plates. The force acting on B would represent the E.M.F. applied to drive the current through the condenser.

The yielding of the membrane or the dielectric constitutes the displacement current. Of course, if the force applied to B in Fig. 1 were sufficiently great, the membranes would be stretched until they reached the rupturing point, when they would rupture, and the water would then flow through in the ordinary way. In the electrical case, if the E.M.F. (either direct current or alternate current) applied to a condenser circuit be sufficiently great, it will rupture

Digitized by Google

or puncture the dielectric, and then the current will have a continuous passage by the arc so formed.

If the rails of the railway referred to are supplied with current from a three-wire system at the outer voltage, then, of course, a person touching one rail receives a shock to earth at about half the working voltage of the system.

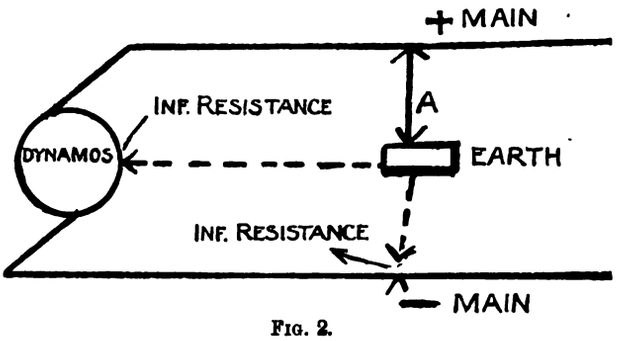

FIG. 2.

Supposing that the insulation resistance of the network were infinite, and that the machines, etc., were perfectly insulated from earth, it would be absolutely impossible to receive a shock upon touching either rail, because there would not be a complete circuit (Fig. 2 makes this point clear; "A" represents the man). With the same insulation resistance on the rails, suppose there is a leak on the machine, then a person touching either rail would complete a circuit from the rail through earth to the machine and round again, and would, of course, receive the shock.

Now, in practice no network has an insulation resistance of infinity, at least for long. Therefore, when any conductor (and all living animal tissue conducts electricity) is connected from either rail to earth, it simply closes a circuit which causes current to flow from that main through the conductor to earth, and from earth either back to the machine or to the other main. This flow of current is due, of course, to the difference of potential existing between either pole of a system and earth.—H. A. CARNEY.

Question No. 826.—What is meant by the all-day efficiency of a transformer? What are the factors to be taken into account in the design of the transformer in order to secure a high all-day efficiency?

Answer to No. 826 (*awarded 7s. 6d.*).—The "all-day" efficiency of a transformer is the ratio of output to input during 24 hours. This ratio may be written thus:

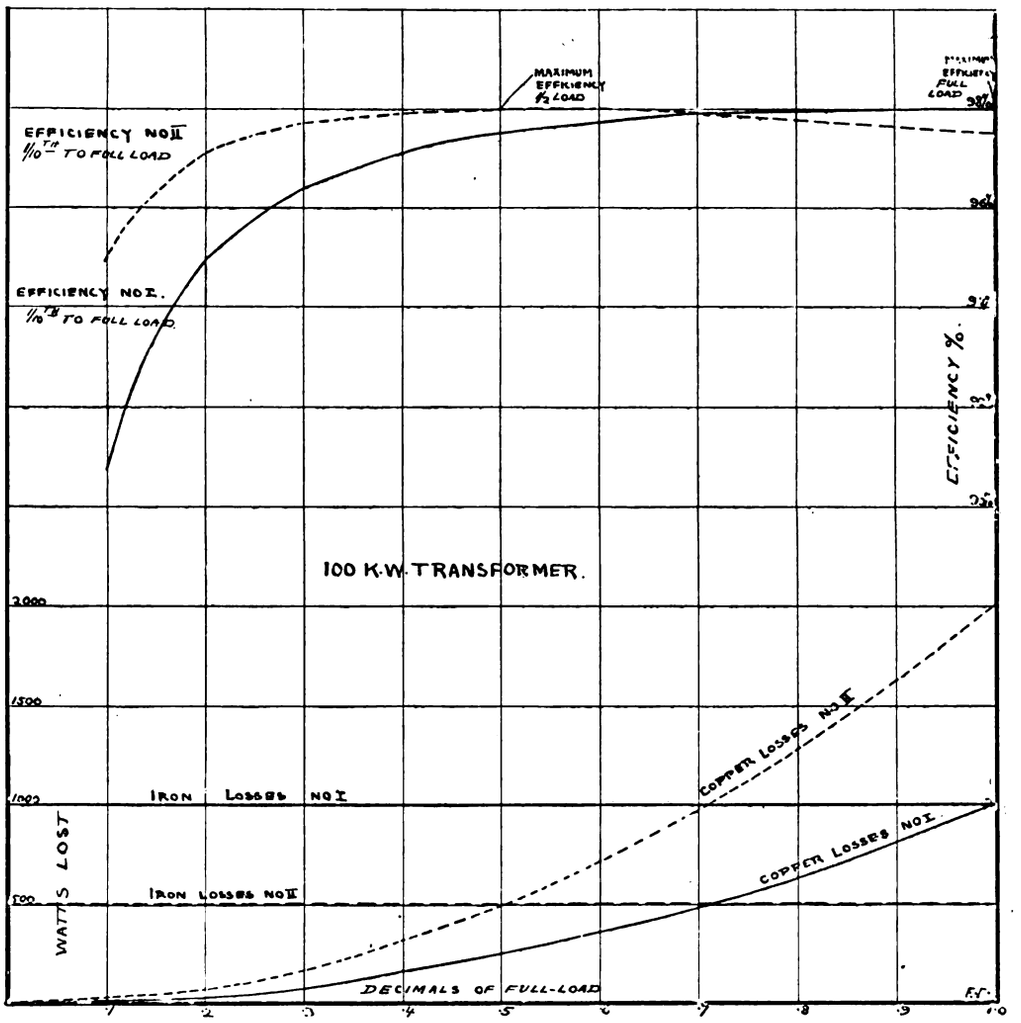
Output of secondary/output of secondary + losses in transformer during a period of 24 hours.

Now, the losses in a transformer may be divided into two sections—copper losses and iron losses. The former vary as the square of the load, but the latter, for all practical purposes, remain constant from no load to full load. A slight consideration will show that in a transformer which is idle during most of the day the constant iron losses have a greater effect in lowering the all-day efficiency than they would have if the transformer was loaded up during a long period. This brings us to the question of load factors, and it is by adjusting the relative amounts of copper and iron losses to suit the load factor of the transformer that a maximum all-day efficiency is obtained.

The curves given in the figure represent the copper and iron losses and efficiency curves of two transformers. Transformer No. 1 has equal copper and iron losses at full load. Transformer No. 2 has equal copper and iron losses at half load, but at full load the copper losses are four-fifths and the iron losses one-fifth of the total losses. It is a well-known fact that the point of maximum efficiency occurs when copper and iron losses are equal, so that, as may be seen from the figure, transformer No. 1 is most efficient at full load and transformer No. 2 at half load. From these curves, knowing the load factor, it is possible to calculate the all-day efficiency as shown below. The load factor is easily arrived at by using the following formula:

$$\text{Load factor} = \frac{\text{actual output of transformer}}{\text{full-load capacity} \times 24},$$

the actual output in this case being taken over a period of 24 hours.



Digitized by Google

Three typical load factors will now be taken, and the all-day efficiency of the two transformers calculated for each load factor.

Load Factor (*a*).—Ten hours full load, 14 hours no load. L.F. = ·4166. 41·66 per cent.

Load Factor (*b*).—Two hours full load, 4 hours three-quarter load, 18 hours no load. L F. = 20·83 per cent.

Load Factor (*c*).—Twelve hours full load, 8 hours three-quarter load, 4 hours no load. L F = 75 per cent.

The all-day efficiency is calculated thus from values in curves :

Load Factor (*b*) *Transformer I.*—

2 hours full load	2 × 2,000 losses	20,000 output.
4 ,, ¾ ,,	4 × 1,562·5 ,,	300,000 ,,
18 ,, no ,,	18 × 1,000 ,,	—
Total losses	28,250	} for 24 hours.
,, output	500,000	

$$\text{All-day efficiency} = \frac{500{,}000}{528{,}250} = \cdot 946 = 94\cdot 6 \text{ per cent.}$$

The losses and outputs are in watt-hours. The following table gives the results :

Load factor.	All-day efficiency. Transformer I.	Transformer II.
41·66 per cent.	96·7	96·9
20·83 ,,	94 6	96·0
75·00 ,,	97·7	97·5

It is evident, then, that transformer No II. is most suitable for a low power factor, and there is not much difference between the all-day efficiencies in the medium and high power factors. It must be remembered, however, that a transformer with low iron losses is bulkier and more expensive than it would be for the same power with losses more evenly distributed, and although this is not part of the question, it should be mentioned that unless the cost of the watt-hours saved per annum by the installation of a low iron loss transformer is greater than the interest on the extra capital necessary to purchase such a transformer no economy will result. As a general rule, however, transformers for power should have iron and copper losses equal at full load, and those for lighting should have the copper and iron losses at full load distributed in the ratio of copper two-thirds, iron one-third of total losses.

It is only intended to indicate by what means high all-day efficiencies may be obtained. The question of actual design to proportion these losses is too large a question to be tackled here.—D. M. HUTCHISON.

Answer to No. 826 (*awarded* 5*s.*).—The losses which tend to lower the efficiency of a transformer are those taking place in the iron and copper circuits. The iron loss represents the energy required to overcome hysteresis and eddy currents in the core, and to magnetise it sufficiently to generate the normal secondary voltage. This loss is practically constant, whether the secondary circuit is open or supplying full-load current, but varies inversely as the frequency of the supply current. The copper loss is caused by the resistance and heating in both windings. It only takes place when the transformer is supplying a useful current, and varies as the square of the current. Now, the losses which affect the efficiency of any transforming system are those which occur at light load, consequently the ratio of the iron to the copper loss in a transformer has an important bearing on its running efficiency. A small iron loss necessitates a more or less large copper loss, and a large copper loss is not desirable, as it affects the regulation in a transformer. Transformers that are only running on full load for a small number of hours during the day, as is the case with a lighting system employing transformer distribution, should have a small iron loss, especially if the cost of energy is high. On the other hand, when energy is cheap, and the transformers are running at or near full load for many hours during the day, they should have a small copper loss. This is where the all-day or running efficiency of a transformer comes in, and this is of greater importance than its testing efficiency in the case of transformers which are only working at full load for a comparatively short period. In practice it is usual to take into account the all-day efficiency on a basis of 20 hours' light-load and four hours' full-load run of a transformer. This means that the copper losses in one day = copper loss at full load for four hours, the iron loss going on during the whole time the transformer is in circuit.

Therefore, the all-day efficiency of a transformer equals

$$\frac{\text{Full load in kilowatts} \times \text{four hours}}{(\text{Full load} \times 4) + (\text{copper loss} \times 4) + (\text{iron loss} \times 24)}$$

And as an example might, perhaps, simplify matters, we shall consider the case of a 6-kw. transformer having iron loss = 95·5 watts, copper loss = 108 watts, and the full-load testing efficiency $= \frac{6}{6 + \cdot 0955 \times \cdot 108} = 96\cdot 6$ per cent.

Now, substituting these values in the formula mentioned above, we get $\frac{6 \times 4}{(6 \times 4) + (\cdot 108 \times 4) + (\cdot 0955 \times 24)}$, which gives an all-day efficiency of 89·8 per cent. As the difference between the all-day and testing efficiency in this example is not very great, it will be interesting to work out what the annual running efficiency would be for the same transformer. Suppose the transformer is working at full load for 1,000 hours during the year. Then the useful work done = 1,000 × 6 = 6,000 kilowatt-hours. Copper loss = ·108 × 1,000 = 108 kilowatt-hours. Iron loss = 8,760 × ·0955 = 836·6 kilowatt-hours. ∴ Total work = 6,000 + ·108 + 836·6 = 6,944·6 kilowatt hours. ∴ Annual running efficiency $= \frac{6{,}000}{6{,}944\cdot 6} \times 100 = 86\cdot 3$ per cent.

This example shows a difference of 10·3 per cent. in the annual running and testing efficiencies of a 6-kw. transformer having a 1·6 per cent. iron loss and a 1 8 per cent. copper loss. It may be shown in a very simple manner that a small decrease in the iron loss, even when accompanied by a relatively large increase in the copper loss, has the effect of substantially increasing the all-day or annual running efficiency of a transformer. For this purpose we shall again consider the case of a 6 kw. transformer, and suppose the copper loss has been increased to 4 per cent., and the iron loss decreased to 1 per cent., the period of full-load working being 1,000 hours as before.

Under these conditions the copper loss $= \frac{6{,}000 \times 4}{100}$ = 240 watts, and iron loss = 60 watts. Then useful work done during 1,000 hours = 6 × 1,000 = 6,000 kilowatt-hours. Total copper loss $= \frac{240 \times 1.000}{1{,}000} = 240$ kilowatt-hours. Total iron loss $= \frac{60 \times 8{,}760}{1{,}000} = 525\cdot 6$ kilowatt-hours. Total work done = 6,765·6 kilowatt-hours. ∴ Annual running efficiency $= \frac{6{,}000}{6{,}765\ 6} \times 100 = 88\cdot 7$ per cent., and testing efficiency $= \frac{6}{6 + \cdot 24 + \cdot 06} \times 100 = 95\cdot 2$ per cent.

Comparing these results with those obtained in the first example we find a decrease in the testing efficiency of 1·4 per cent., and an increase in the annual running efficiency of 2·4 per cent, which is of much greater importance, taking into account the conditions of working. As regards the factors to be taken into account in the design of transformers, the conditions under which they have to work should be known beforehand. The testing efficiency is highest when the iron and copper losses are equal, but as this is quite a secondary consideration in some cases, the distribution of losses must be suited to the conditions under which a transformer is to work. The aim in the design of transformers which will only be occasionally fully loaded is to keep the iron loss as low as possible, as this loss is continuous whether the transformer is doing useful work or not.—W. ROGERS.

[Other replies to Question No. 826 will be given in our next issue.—ED. *E. E.*]

DECEMBER 15, 1905.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

833. What is the method of determining the conversion ratio (alternate current to direct current) of a rotary circuit?—W. A. J.

834. A correction is made for heating when using an electromagnetic voltmeter, but not when using an ammeter of the same type. Why is this? Give a method by which it is possible to determine the error per cent. due to heating in an electromagnetic voltmeter?—METER.

ANSWERS.

Question No. 826.—What is meant by the all-day efficiency of a transformer? What are the factors to be taken into account in the design of the transformer in order to secure a high all-day efficiency?

Best Answer to No. 826 (*awarded* 10*s.*).—Many alternating-current transformers are only partially loaded for a great part of the time that they are in circuit. The full-load efficiency of the transformer does not in such a case give the engineer a satisfactory indication as to whether the transforming plant is working under the most economical conditions, as although the full-load efficiency may be very high, the no-load loss may be relatively large. Although a transformer may be on open circuit or no load, energy is taken from the mains to supply the no-load loss occurring in the laminated iron core due to the periodic reversals of the magnetic flux, which loss is at constant voltage a constant at all loads. If the transformer is only fully loaded for a comparatively short period of the time it is in circuit, the energy required to supply the constant no-load loss amounts to a relatively large percentage of the useful output from the transformer, and as this is not paid for by the consumer it is thus a dead loss to the system. Hence, in order to secure economical working of the plant, a knowledge of the no-load loss is required, and also the time during which the transformer is loaded. These factors are included in the term "all-day" efficiency, which may be defined as the ratio: Output of transformer in kilowatt-hours extending over the whole day/input to transformer in kilowatt-hours extending over the whole day.

For approximate calculations the ratio may be written:

$$\frac{100\ \mathrm{L}\ .\ \epsilon}{10{,}000\ \mathrm{L} + x\ .\ \epsilon\ (1-\mathrm{L})},$$

where L is the "load factor"—*i.e.*, the ratio: Number of hours transformer is fully loaded/number of hours transformer is in circuit—ϵ is the percentage full-load efficiency, and x the percentage iron or no-load loss (reckoned on the full-load output).

It will be observed that with 100 per cent. load factor—*i e*, full load for the whole time the transformer is in circuit—the all-day efficiency has its maximum value, which is equal to the full-load efficiency of the transformer, while with zero load factor the all-day efficiency likewise becomes zero. If, however, the transformer is run for a long period at, say, quarter load, the results obtained by using the above formula will be a few per cent. lower than the true all-day efficiency.

The formula is deduced as follows: Let W denote the full-load output in kilowatts of the transformer, c the number of hours corresponding to full load—*e.g.*, if the transformer is loaded for, say, 1½ hours at actual full load and three hours at three-quarter load this may be considered (for all practical purposes) as equivalent to 3¾ hours at full load). The output from the transformer for the day will be $\mathrm{W} \times c$ units, while the "all-day" input will be $\frac{110\ \mathrm{W}\ c}{\epsilon} + a\ (24 - c)$ units, where ϵ is the percentage full-load efficiency and a the no-load loss in kilowatts. Introducing the load factor, L, and remembering that $\mathrm{L} = \frac{c}{24}$, we have all-day efficiency

$$= \frac{\mathrm{W} \times \mathrm{L}}{\frac{100\ \mathrm{W} \times \mathrm{L}}{\epsilon} + a\ (1 - \mathrm{L})}.$$

Now, if x and y represent the constant and variable losses—*i e*, iron and copper losses—at full load in per cent. of the full-load output, we have $\epsilon = 100 - (x + y)$, and $a = \frac{\mathrm{W}\ .\ x}{100}$. Hence the expression becomes: All-day efficiency

$$= \frac{\mathrm{W} \times \mathrm{L}}{\frac{100\ \mathrm{W} \times \mathrm{L}}{100 - x - y} + \frac{\mathrm{W}\ .\ x}{100}(1 - \mathrm{L})}$$

$$= \frac{100\ \mathrm{L}\ (100 - x - y)}{10{,}000\ \mathrm{L} + x\ (1 - \mathrm{L})\ (100 - x - y} = \frac{100\ \mathrm{L}\ \epsilon}{10{,}000\ \mathrm{L} + x\ .\ \epsilon\ (1 - \mathrm{L})}.$$

Data will be found in Table I. relating to four designs for 50-kw. 50 ~ transformers, the maximum efficiency being 98 per cent. in each case, this occurring at quarter, half, three-quarter, and full load respectively. The all-day efficiency is also given for various load factors, that of 12½ per cent. being typical for lighting circuits, while the higher values apply to power circuits. It will be observed that in design A the all-day efficiency is very nearly constant for a great range of the load factor. Although this design shows the highest all-day efficiency (at a low load factor) of the series, the all-day efficiency does not, however, improve at the high load factors, being only 95·75 per cent. for unity load factor, while design D shows an all-day efficiency of 98 per cent. at this load factor. This shows that for economical results transformers should not be used indiscriminately, as a transformer designed for lighting loads, such as designs A and B, will give a poor all-day efficiency on a power load, and, conversely, a transformer designed for a power load such as design D will give uneconomical results on a lighting load.

In the design of transformers we have the following points to take into account—viz., temperature rise, efficiency, regulation, and cost. For lighting circuits a high efficiency is required on light loads, while for power supply high full-load efficiency and good regulation are required. In the former case the no-load loss must be as small as possible, and the C^2 R or copper loss should be as high as is consistent with suitably low temperature when running on full load and with suitable regulation in the secondary circuit. In large transformers heating is generally the limit, while in small transformers the required regulation—*i.e.*, percentage drop in volts from no load to full load with constant applied voltage—is more often the limit. These limitations of heating and regulation are encountered when an attempt is made to secure a low no-load loss, and it is a considerable help to the designer that lighting loads are non-inductive, as with a power or motor load good regulation under these conditions would still be more difficult on account of the wattless component of the current. The most successful direction in which to decrease the no-load loss would be to increase the number of turns in the windings and decrease the cross-section and weight of iron in the magnetic circuit. The relation between turns, flux, and voltage is given by

$$\mathrm{E} = 4{\cdot}44\ \mathrm{T}\ .\ \mathrm{N}\ .\ \mathrm{M} \times 10^{-8},$$

where E is the R.M.S. value of the "internal" E.M.F., T the number of turns, M the magnetic flux linked with

* Reckoned on the full-load output. † Four hours at three-quarter load, 20 hours at no load. ‡ Twelve hours at full load, 12 hours at no load.

NOTE.—The prices of above transformers for power are 8·16 per cent. lower in the 100-kw. size than the corresponding size of transformer for lighting. For the 1-kw. size the price of the power transformer is 6·6 per cent. lower than one of the same size for lighting.

the turns T (in megalines), and N the periodicity in ~ per second. In a given design a reduction in the flux, M, means an increase in the number of turns, T, which is followed by an increase of the inductance of the transformer, and consequently a greater voltage drop from no to full load. However, as a lighting load is non inductive, a relatively large number of turns may be employed without seriously affecting the regulation. The question of regulation, however, needs to be considered from the financial standpoint with a lighting load, for the difference between, say, a 2 per cent. drop and one of 1·75 per cent. on full load may be that with a given number of lights on through a wattmeter the net revenue is increased several per cent. and the customer is better pleased with the light. This is because the difference in watt-hours, due to the difference in the drop in the two cases, is paid for by the consumer at probably maximum demand prices.

With an inductive load good regulation can be obtained by reducing the number of turns, thus increasing the flux, and by suitably intermixing the primary and secondary turns. As, however, an inductive load has generally a fairly good load factor, the iron may be worked at a higher density, thus increasing the core loss and reducing the weight within commercial limits to offset the greater flux, since with a smaller number of turns the C^2R loss will be reduced. In order to show the difference between transformers designed for lighting from those designed for power loads, Table II. has been prepared from data supplied by manufacturers.

It has been pointed out that for a lighting load it is customary to design a transformer with a relatively large number of turns and small cross-section of iron in order to reduce the no-load loss. This entails a correspondingly large copper loss, but as the transformer is seldom fully loaded for more than three consecutive hours, the temperature rise due to this loss can be kept within limits. With transformers for power supply, which would be fully loaded for several hours at a time, such a large copper loss would lead to an excessively high temperature rise unless special devices were resorted to for cooling. However, as we have previously seen, the copper loss in transformers for power supply must be kept low in order to obtain good regulation, and thus the temperature rise can be kept within the specified limits In submitting transformers to full load tests, due consideration should be given to the load factor which the transformer is designed for, as it would be absurd to demand a satisfactory 24 hours' run at full load from a transformer designed for lighting purposes where the load factor would probably be about 12 per cent. The duration of the heat run should vary according to the load factor as indicated below:

For a load factor up to						
10	per cent.	heat run	should	consist of	3	hours' run at full load
25	"	"	"		6	" "
50	"	"	"		12	" "
75	"	"	"		18	" "
100	"	"	"		24	" "

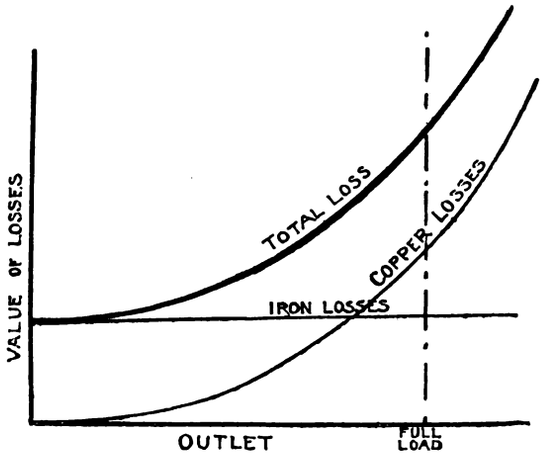
The average temperature rise after above runs should not exceed 45deg. C or 50deg. C as measured by the increase of resistance of the windings. A high temperature should be avoided, as this has a considerable effect in increasing the no-load loss due to "ageing."

As the relation between efficiency and cost of transformers has recently been fully dealt with by Dr. R. Pohl and H. Boble in an article, "Calculation of Alternate-Current Transformers for Minimum Cost," the rules enunciated by these investigators deserve careful consideration. These

Digitized by Google

authors, in concluding their article, state "that the price of the active material of a 50 kilovolt-ampere transformer for an efficiency of 98 per cent. is nearly 3½ times higher than that for the same transformer with an efficiency of 97 per cent, while for an efficiency of 97 5 per cent. the price of active material is slightly double that for the design for 97 per cent. efficiency. In the case of the design for 97 per cent. efficiency, effective artificial cooling would be necessary" in order to keep the temperature rise within the customary limits. (See the *Electrical Engineer*, vol. xxxvi., pp. 446 to 449 and pp. 519 to 521, Sept. 29 and Oct. 13, 1905).—MONOPHASE.

Answer to No. 826 (*awarded* 7*s.* 6*d.*).—The all-day efficiency of a transformer may be regarded as the ratio of the output from the secondary terminals to the input of the primary taken over a period of 24 hours. Now, the value of this ratio depends on two things: (1) the kind and value of the losses in the transformer and (2) the loading of the transformer. The second consideration, it will be seen later, to a certain extent controls the first. It is easily conceivable that two transformers might be built having the same full-load efficiency, say 97 per cent., but one having a small ohmic loss, say 1 per cent., and a large iron loss, 2 per cent.; whilst the other has a large copper loss (2 per cent.) and a small iron loss (1 per cent.). Now, if these two transformers work at full load for 24 hours, it is evident that they will both have the same all-day efficiency. But if they are only run at full load for three hours out of the 24, it will then be seen that the transformer with the smaller iron losses (these being present to practically the same extent at no load as at full load) will have the greater all-day efficiency. Therefore, in designing a transformer, the best all-day efficiency cannot be obtained unless some idea of value of the loading is obtained.



The accompanying diagram shows the manner in which the losses vary according to the loading of a transformer. It will be seen that the total losses are made up of a practically constant part, H, and a part varying with the load. Assuming that the secondary current is exactly proportional to the primary current, and that the E M.F. is constant, we may consider the varying losses as being proportional to the square of the primary current, C. Therefore, at any loading: total losses $\propto H + k C^2$, k being a constant.

$$\text{Efficiency, } \eta = \frac{\text{watts applied} - \text{watts lost}}{\text{watts applied}}$$

$$\therefore \eta = \frac{E C - (H + k C^2)}{E C} = 1 - \frac{1}{E}\left\{\frac{H}{C} k + C\right\}$$

η and C are the variables, so to find the load for maximum efficiency differentiate with regard to C and equate to zero.

$$\therefore \frac{d \eta}{d C} = + \frac{H}{E C^2} - \frac{k}{E} = 0$$

$$\therefore k C^2 = H.$$

i e, for maximum efficiency the variable losses must equal the constant losses. Therefore, if a transformer is being designed that will work at full load all day, make the variable losses equal to the constant losses for best all-day efficiency.

The following data of a design taken from "Transformers," by Prof. G. Kapp, will illustrate the fact that a machine with the best full-load efficiency has not necessarily the best all-day efficiency. The machine is a 15-kw. single-phase transformer of the core type. A rough design was first obtained by assuming standard proportions for the core, a flux density of 5,000 lines per square centimetre, then adjusting primary and secondary windings to share equally the available copper losses found by subtracting the calculated iron losses from the total permissible loss. This attempt resulted in a machine which has at full load copper losses amounting to 321 watts and iron losses to 161 watts; consequently the maximum efficiency occurs at a load less than full load where the above two losses were equal (at about 11 kw.). To improve the design to give better efficiency at full load, the windings were altered so as to increase the flux density by such an amount as would bring up the iron loss to half the total of the above losses—*i.e.*, half of 482. The flux density chosen was then 6,300 per square centimetre, and the turns altered according to formula $E = 4{\cdot}44\ f\ N\ S \times 10^{-8}$; where E = applied E M.F., f = frequency (50), N = total flux, and S = number of turns in primary. This design gave the two losses equal at 16 kw.; consequently the linear dimensions were reduced in the ratio of $\sqrt[3]{\frac{15}{16}}$ and the losses in the ratio $\frac{15}{16}$, so as to be able to compare this last design with the first. Table A shows the principal factors in each design. The last item in the table—cost per kilowatt—is the cost of active material, taking finished laminations at 9d. per kilogramme (4d. per lb.) and insulated copper wire at 1s. 9d. per kilogramme (9½d. per lb.). The figures show that both as regards full-load efficiency and costs that design I. is much better than design II.

TABLE A.

	I.	II.
Flux density (lines per sq. cm.)	5,000	6,350
Output kilowatts	15	15
Temperature rise (deg. Cent.)	49·3	49

Ohmic loss	321	208
Total loss	482	428
Percentage loss	3·22	2·85
Weight per kilowatt output (in kg.)	19 4	18·4
Cost per kilowatt output (in s.)	21 9	20·9

TABLE B.

Lamps alight.	Hours.	Lamp-hours.	Watts.	Loss in B.T.U.
100	50	5 000	100	5
70	100	7 000	49	4 9
40	500	20 000	16	8
20	1,000	20,000	4	4
10	800	8 000	1	0·8
	2,450	60,000		22 7

But now let us consider the working of the two transformers on a lighting load where the full load is only on for a comparatively short space of time. For this purpose we shall take for our standard time one year (8,760 hours), because the all-day efficiency depends on the time of the year, whilst the all-year efficiency is practically the same every year. Assume that the installation has 100 lamps which have an average burning time of 600 hours per year, and that the ohmic loss in the transformer when full load is on is 100 watts. Then, if lamps are used according to times given in Table B, the loss due to the ohmic resistance in the transformer is 22·7 B.T.U. per annum. The fourth column if obtained thus: if 100 lamps mean a loss of 100 watts, then x lamps will mean a loss of $\frac{x^2}{100}$ watts; because loss varies as the square of the current—*i e*, as the square of x. Now, on the basis that 100 watts lost at full load due to resistance means 22·7 B.T.U. per annum, design I. will have a loss of $22{\cdot}7 \times \frac{321}{100} = 73$ units per year and design II. of $22{\cdot}7 \times \frac{208}{100} = 47{\cdot}3$ units per year. The hysteresis losses amounting to $\frac{161 \times 8{,}760}{1{,}000} = 1{,}410$, and $\frac{220 \times 8{,}760}{1{,}000} = 1{,}930$ units per year. Arranging in tabular form we get;

Digitized by Google

	I.	II.
Annual ohmic loss in units	73	47·3
,, hysteresis ,,	1,410	1,930
,, total ,,	1,483	1,977·3
,, output ,,	9,000	9,000
,, efficiency per cent.	86	82

Thus we see that on loading taken, although design II. has the better full-load efficiency, design I. has the better annual efficiency. Now, taking the selling price at about 2¾ times the cost of active materials, the net cost would be for design I. £45, and design II. £43. The difference is only £2, against which we have a saving of 494 units per annum by choosing design I. Taking cost of a unit at 1d., this means £2 1s. 2d. yearly—that is, design I. pays for its extra cost in one year. Thus we arrive at the conclusion that if transformers are to be used for power, make the iron and copper losses approximately equal, but if for lighting, iron loss small and the copper loss larger.—F. H. C.

Question No. 827.—Explain clearly, with diagrams if necessary, the "La Cour" system of compounding motor-generators.

Answer to No. 827 (*awarded 7s. 6d.*).—The La Cour motor-generator, or "cascade converter," for transforming alternate currents into direct currents, consists of an ordinary single, two, or three phase induction motor, direct-coupled mechanically to an ordinary direct-current dynamo. The rotor winding of the induction motor is also connected electrically to the armature winding of the direct-current dynamo winding at three, six, nine, or more equidistant points by wires carried across between the two machines. The rotor of the induction motor is, further, usually fitted with three slip-rings for starting purposes, but these are short-circuited under normal working conditions. The connections are shown diagrammatically in Fig. 1. The

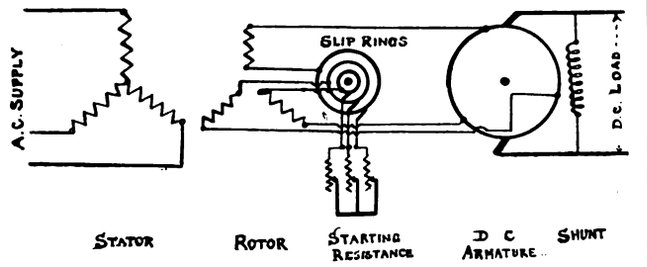

FIG. 1.

alternate-current supply has been taken as a three-phase one, and also only three connecting wires are shown between the rotor and armature, though it is more usual to employ six or nine connections, because this, as in the case of an ordinary rotary converter, reduces the heating of the armature. It will be seen that there is no direct connection between the alternate-current supply and the direct-current output, so that any required voltage ratio between the alternate-current and direct-current sides can be obtained by suitably arranging the relative numbers of turns in the stator, the rotor, and the direct-current armature.

This type of converter can be readily started on the alternate-current side with no more trouble than that involved in starting an ordinary induction motor. The alternating-current supply is switched on to the stator of the induction motor, and the starting resistance between the slip-rings is gradually reduced. Instead of cutting all this resistance out, however, and allowing practically synchronous speed to be attained, as in the case of an induction motor, only sufficient resistance is cut out to enable the machine to reach half synchronous speed (supposing that both induction motor and dynamo have the same number of poles as is usually the case). This half synchronous speed is the normal speed of the set, and the direct-current dynamo will, therefore, excite itself and induce the normal voltages in its armature at this speed. The connections between rotor and direct current armature are arranged so that at half synchronous speed the voltages induced in the direct-current armature are practically equal and opposite to the voltages induced between the corresponding points of the rotor winding by the inducing action of the stator, so that, if the direct-current machine's excitation is correct, only enough current will flow in the rotor circuit to keep the set running.

At this stage the slip-rings can be completely short-circuited either by the starting switch or by an internal short-circuiting device, and the set will then continue to run at exactly half synchronous speed, and the direct-current side can be switched on to the feeders and loaded up. At half synchronous speed the slip (or difference between the rotor speed and the speed of the stator rotating field) of the induction motor is 50 per cent. of the synchronous speed or the ~ of the voltages induced in the rotor is 50 per cent. of the supply ~, whilst the ~ of the voltages induced in the direct-current armature (the number of poles being the same in both machines) is also equal to 50 per cent. of the supply ~. The rotor circuit, therefore, contains two sets of nearly equal and opposite voltages of the same periodicity. As soon as a load is taken from the direct-current side, the opposing voltage of the direct-current armature is reduced by armature reaction and loss in armature resistance, and more current flows from the rotor into the armature, the stator of the induction motor at the same time taking more current from the line. This increased rotor current produces an increased torque in the induction motor, and the limit of increase of rotor current is reached when this torque is equivalent to half the load taken from the direct-current side—the rotor current itself supplying the other half of this load by passing more or less directly into the direct-current feeders, after traversing little or none of the direct-current armature winding. In this way approximately half the power is transmitted to the direct-current side mechanically through the spindle, and the other half electromagnetically through the connecting wires between the rotor and the armature.

It has been assumed above that the excitation of the direct-current machine has been adjusted to give equality of voltage between rotor and armature. If this is not the case, the machine will automatically adjust matters just as in the case of a synchronous alternating motor under similar circumstances — *e g*, if the dynamo is over-excited, an increased current, lagging relatively to the induced voltage in the direct-current armature, will flow in the rotor and armature circuit (accompanied, of course, by a corresponding rise in stator current), and will have such an amount and such a phase relation to the induced voltage as to weaken the dynamo field to the required amount to restore the balance. As this balance between the rotor and direct-current armature voltages is regained partly by field weakening (through armature reaction) and partly by phase displacement, it is obvious that the dynamo field, though reduced from its original over-excited state, is still not reduced to its normal value. The reduction to normal value would only occur if field weakening alone were employed for restoring the balance. It is on this account that such a converter possesses self-regulating properties if the dynamo is compound wound. As the direct-current load increases, the series winding on the dynamo is made to over-excite the field to a greater and greater extent, and so, whilst the phase displacement between the alternating supply voltage and current increases, the magnetic flux per pole of the dynamo also gradually rises with the load, and the dynamo brush voltage rises correspondingly. The makers of these machines state that, without letting the power factor of the alternating supply fall below ·93 at any load, a rise of direct-current voltage of as much as 20 per cent. between no load and full load can be ensured with constant alternating-current supply voltage.

The chief advantages of such converters may be stated as follows: (1) half as many poles required in the induction motor as in the case of an ordinary motor-generator for the same ~ and speed; (2) independence of the alternating-current and direct-current voltages; (3) self-regulating power; (4) higher average power factor than in the case of the ordinary motor-generator; (5) easy starting on the alternating-current side; (6) greater stability in running than in the case of an ordinary rotary converter.—Q.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

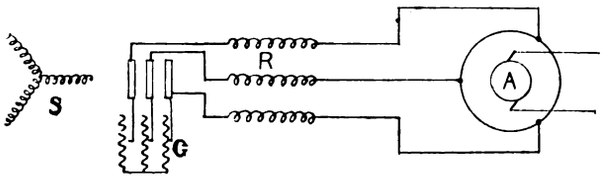
835. Describe a cheap and simple form of electric telegraph for communication between switchboard and engine-room, making use of as few wires as possible.—E. A. A.

836. A certain newspaper printing-machine motor—35 h.p., 500 r.p.m., 480 volts, six-pole (per set)—has two complete armatures on the same shaft and two separate sets of field coils in same magnet frame. One set is wound shunt and the other series. How should this motor be coupled up to its starter or controller?—E. B.

ANSWERS.

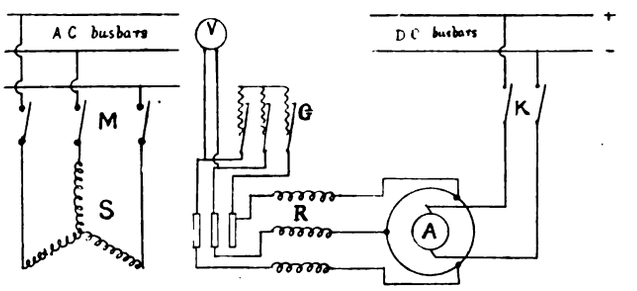
Question No. 827.—Explain clearly, with diagrams if necessary, the "La Cour" system of compounding motor-generators.

Answer to No. 827 (*awarded 7s. 6d.*).—Machines built according to the La Cour system are, as far as constructional details are concerned, very little different from induction motor-generators, except that, in addition to the ordinary mechanical connection between the motor and the generator, there is also an electrical connection. Thus, instead of having two practically independent machines connected merely by a coupling, we now have a compound machine which acts partly as an induction motor-generator and partly as a rotary converter. To see how this occurs, consider an ordinary three-phase induction motor whose rotor, R, is mechanically connected by a shaft to the armature, A, of a direct-current generator. In the La Cour system one side of the rotor winding is connected through slip-rings to a starting resistance, G, in the usual way, but the ends on the other side, instead of being short-circuited



as in an induction motor, are connected to suitable tapping points on the direct-current armature, A. When an alternating current flows in the stator, S, it induces currents in the rotor windings whose frequency depends on the slip of the rotor relative to the revolving stator field. Thus, if w_1 is the angular velocity of stator field, w_2 the angular velocity of the rotor, and n the frequency of the supply, the frequency of the rotor currents is $\frac{w_1 - w_2}{w_1} . n$. We may, therefore, consider A as the armature of a rotary converter supplied with current at this frequency. If the direct-current machine is so wound that when used as a rotary converter on the same source of supply as the induction motor, it would run at the speed at which the induction motor would run if there were no slip, it is easy to see that the compound machine will be synchronous, and will run at half the normal speed of either machine when running separately off the supply. For if the induction motor is running at more than half speed, w_2 is greater than $\frac{w_1}{2}$, and, therefore, the frequency of the rotor currents is less than $\frac{n}{2}$. If the rotary converter which is fed by these rotor currents is to keep in synchronism with its supply, it must run at less thanhalf its normal speed. This it is prevented from doing, since it is mechanically connected to the rotor of the induction motor, which we have assumed to be running at more than half normal speed. Similarly, it can be seen that if the speed of the induction motor is less than half normal, the synchronous speed of the rotary will be greater than half normal. If the combination is running exactly at half speed, however, the frequency of the rotor currents is $\frac{n}{2}$, and this is just the frequency required to run the rotary converter at half speed, so that the arrangement is now stable.

The compound machine can now be seen to possess the following advantages: (1) Since the rotary converter is supplied at half the supply frequency, it will run stably with a supply frequency of twice that which can be used with an ordinary rotary. This would enable the standard frequency of 50 to be used both for lighting and traction. (2) There is no need for separate tranformers for the rotary, since transformation is effected by the induction motor, which can be wound for the full line voltage. (3) For a given speed of the induction motor only half the usual number of poles are needed in the stator winding, since the winding is the same as that for an induction motor of double the speed. This means that the diameter of the stator can be diminished. (4) It is started up from the alternating-current side, and is easier to synchronise than an ordinary rotary.

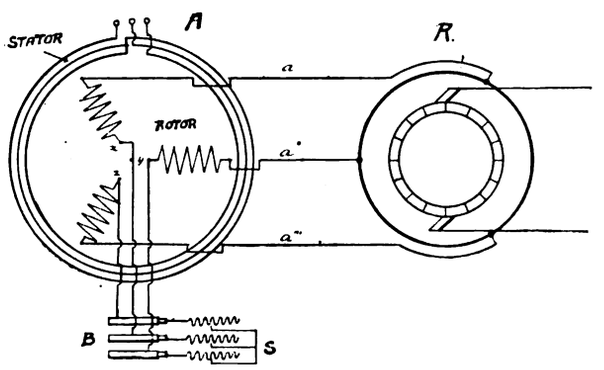


The starting connections can be seen from the accompanying diagram. The stator, S, is directly connected through the main switch, M, to the alternating-current 'bus bars. The rotor, R, is connected on one side through slip-rings to the starting resistances, G, and on the other by means of a hollow shaft to the proper points on the direct-current armature, A. The direct-current side of the armature is connected to the direct-current 'bus bars through switches, K. The synchronising voltmeter, V, is placed across the two leads from the slip-rings. In starting, the direct-current side is not touched at all, since the machine is self-exciting, and all that is necessary is to close the main alternating-current switch, M, and then to adjust the speed by means of the resistances, G, until the voltmeter, V, reads zero. When this has been done, synchronising is effected by suddenly short-circuiting the resistances, G. The slip rings are then short-circuited on the machine and the direct-current side paralleled in. When the main switch, M, is closed, the ends of the rotor connected to the direct-current armature are practically short-circuited, and the machine starts up as an induction motor with a resistance in the rotor. At a certain speed, however, the rotary will get into phase with the rotor currents, and will generate E M.F.'s which will oppose the E M.F.'s in the rotor, and the rotor currents will, therefore, be choked down to quite a small value. Since the resistances, G, are non-inductive, this means that the voltage across the slip-rings will be very small, and the voltmeter, V, will read nearly zero, hence the resistances can be cut out without short-circuiting the rotor. If they were cut out when the rotary was not

Digitized by Google

in phase, the rotor would be short-circuited at both ends, and since it would only be running at half the speed at which it should run as a pure induction motor, an excessive current would be taken by the stator. These machines are manufactured in this country by Messrs. Bruces Peebles and Co., and have been installed in several sub-stations in different parts of the kingdom.—J. R. BEARD.

Answer to No. 827 (*awarded* 5*s.*).—The La Cour system of motor-generator consists in mechanically coupling an asynchronous motor to a rotary converter, the secondary winding of the motor being connected to equidistant points in the armature winding of the converter. The accompanying figure shows a three-phase star-connected motor, A, coupled to a rotary converter, R, which is shown as a



two-pole armature for clearness' sake. The secondary or rotor winding of the motor is also three-phase star-connected, each leg having one connection to a slip-ring on the motor shaft and the other to a point in the armature winding of the converter. The slip-rings are shown at B, and have brushes bearing on them which are connected to a starting device, S, of the resistance type. On starting the motor, all the resistances are placed in circuit with the rotor circuit. They are gradually cut out as speed is gained, and at the final speed they are cut out altogether, the points x, y, z forming the common star point of the rotor winding. The connections a' a'' a''' are led through a hollow shaft from the motor to the converter. If, as is usually the case, the rotary converter and induction motor have the same number of poles, then the stable condition of running holds when the rotors revolve with half the speed of the primary rotating poles of the motor—*i.e.*, the motor revolves at half the speed it would run at normally if disconnected from the converter. Hence, if the primary circuit is 50 ~, the secondary circuit will be 25 ~, and the converter will receive current at the latter periodicity, which is more advantageous on account of sparking and heating with the higher frequency. To show that this is so, let R_1 = the synchronous speed of the motor in revolutions per minute, and p_1 = number of poles in the motor. Let R_2 = the revolutions per minute of the set at any time, and p_2 = the number of poles in the rotary converter. In order that the rotary may run in synchronism with the current supplied from the secondary of the motor, it is necessary that

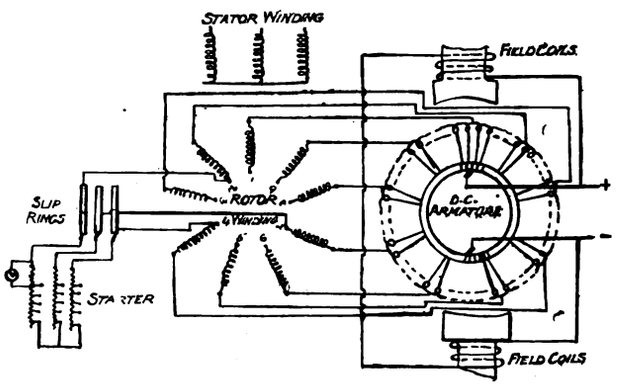
$$(R_1 - R_2)\,p_1 = R_2\,p_2 \quad . \quad . \quad . \quad . \quad (a)$$

and since $p_1 = p_2$ by assumption,

$$R_1 = 2\,R_2, \text{ or } R_2 = \tfrac{1}{2}\,R_1.$$

If p_1 be different from p_2, R_2 will be a different fraction of R_1. A three-phase rotor is always used in this system, but it is obvious that the primary circuit may have any number of phases so long as a rotating field is produced in the motor.—R. D. A.

Answer to No. 827 (*awarded* 5*s.*).—The La Cour motor converter is essentially a synchronous motor direct-coupled to a rotary converter mechanically, the secondary winding of the motor coupled electrically in series to the armature winding of the converter. Or it may be called an induction motor direct-coupled to a direct-current generator, the rotor windings being in series with the direct-current armature. Reference to the diagram below will reconcile the two statements when the action of the set is seen. Keeping to the first definition, if the motor and converter have an equal number of poles, the speed of rotation corresponding to half the frequency of the impressed supply, a field is induced by the supply in the motor rotor, and this field rotates relatively to the rotor in the above proportion. Hence an E.M.F. of half the supply frequency is induced in the rotor windings, causing a current in the converter armature, which in turn sets up a rotating field relatively at the same speed as the shaft. The converter armature is connected to the rotor so that this field rotates in the opposite direction to the shaft, and is thus motionless, being at the same speed, hence the machine works as a synchronous motor. Half the impressed energy is thus converted into mechanical energy and transmitted to the converter, the other half retained as electrical energy and



given to the converter armature through the rotor. If the motor and converter poles differ in number, the rotation speed ratio to that of the impressed frequency would be that of the number of poles of the motor to the sum of the number of poles of motor and converter. The motor thus works as transformer and motor, the converter as rotary converter and direct-current generator. To start the set from the alternating-current end, only three of the phase windings of the rotor are used, these three being connected through slip-rings and a non-inductive resistance to a neutral point. The supply is taken direct to the stator, and the action is that of an induction motor; the resistance is gradually cut out as the speed increases. The converter is on open circuit, the phase windings, other than the three above, being connected to the winding as shown. When the machine is running synchronously, as seen by the voltmeter needle, the rings are short-circuited by means of a handle on the machine, thus connecting all the rotor phase windings. Starting on the direct-current side is, of course, permissible, and if a supply exists, the machine is run up to speed and synchronised in the usual way.—S. E. T.

Question No. 828.—Is there any formula giving for a magnetic blow-out the connection between sparking distance, voltages of supply, current to be broken, distances of the pole-pieces, and number of ampere-turns on blow-out coils?

Answer to No. 828 (*awarded* 10*s.*).—There is not, as far as I know, any well-known formula connecting the various data mentioned in the question. Makers usually have to rely on their previous experience and their own experiments when designing the blow-out magnets. The chief aim, however, is to obtain as powerful a magnetic field as possible without making the magnets an undue size or expending more than a reasonable amount of power in their windings. For such a formula to be of any practical use, it must of necessity be of the empirical variety, derived from experimental data. The necessary experiments should present no very serious difficulties, although such things as shape and material of contacts and atmospheric conditions are likely to produce serious disturbing effects. The deduction of a formula from theoretical considerations is a matter of little difficulty, but, as the following investigation will show, such a formula is of little use, as it necessitates the employment of some uncertain physical constants. The total flux, N, due to the magnets can be easily calculated from the following formula:

$$N = \frac{\text{ampere-turns on magnets}}{\frac{l}{A} + \frac{v\,l_1}{A_1\,\mu}}$$

Digitized by Google

where l = length of air-path;
A = area of air path (area of pole face;
l_1 = length of iron path;
A_1 = section of iron;
μ = permeability of iron;
v = leakage coefficient.

For every voltage there is (keeping other conditions the same) a definite length of gap, l_0, which the arc will just bridge. This length will depend on many conditions, and must be found experimentally for those particular conditions.

On opening the circuit an arc is formed, and, due to the resistance (both ohmic and back E.M.F. of volatilisation), the current is reduced to a certain more or less definite but

$$\text{unknown value} = \frac{V + C\,r}{C\,V} = C_1,$$

where V = voltage of supply;
C = current broken;
r = resistance of arc.

Then considering the arc as a flexible conductor in a magnetic field it will be acted on by a certain deflecting force at right angles to its length; this force will be equal to

$$\frac{C_1\,l\,N}{A \times 11{,}303{,}000} \text{ lbs.}$$

Due to this force, the arc will be deflected, and, therefore, lengthened a certain amount, but in general will be maintained in equilibrium under the action of the deflecting force and the tension along the arc. If, however, the new length be greater than that found for the given voltage, l_0, the component of the tension will not be sufficient to balance the deflecting force, and the arc will be blown out. It must be remembered, however, that the deflecting force in the new position is not that given by the formula above, for, owing to the lengthening of the arc, its ohmic resistance has been increased and the current, therefore, reduced. The effective length, however, still remains the same, l, although the actual length, l_{11}, and the shape of the arc has altered. So that in the new position we have

$$\frac{C_{11}\,l\,N}{A\,11\,303{,}000} = 2\,T \sin\alpha \text{ (component of tension)},$$

where α = angle that the arc makes at the ends with the straight line joining the contacts. The angle α in the limiting case can be obtained from the fact that

$$l/l_0 = \cos\theta.$$

The formula involves a knowledge of three quantities which may vary enormously under different conditions—*i.e.*, B.E.M.F. of volatilisation, ohmic resistance of arc, tension in arc—and would, therefore, have to be specially determined for any particular case. We thus see that in any case experimental work is necessary. It does not require much consideration to see that it would be far more expeditious and convenient, instead of determining these awkward physical quantities, to obtain a direct relation between the actual quantities by obtaining a series of observations connecting them, and fitting an empirical formula to them.—B. Sc.

Question No. 829.—When a conductor is charged with electricity, the whole charge resides on the surface of the conductor; when, however, the conductor is carrying a current, the whole cross-section of the material is in use. How can these two commonly accepted facts be reconciled?

Best Answer to No. 829 (*awarded* 10*s*).—To answer such a question as this in the space at disposal necessitates that a brief explanation can only be given, and due allowance must be made if a kind of mist seems to obscure some portions. If we take two common metal spheres and place them in the air, we know for certain that the forces that are within them, and the forces possessed by the air which surrounds them, are as near equilibrium as possible; by ordinary measurement there cannot be detected any difference. But we know that their essential properties differ, for when they are subjected to a similar force they each differ fundamentally in their reactions—that is, manifest a greater or less degree of energy. Now, when matter is in motion we say that such a body possesses momentum or energy, but matter could not attain motion unless it was subjected to a force, and since, if we regard as existing in the universe matter and ether, which can be regarded as a perfect fluid in which matter resides, it must be an etheric force which causes matter to attain a motion and so manifest energy, just as a ship will attain motion when subjected to the sea waves from which it takes it energy. Now suppose we regard each atom of matter as being built up of primitive or primordial atoms in motion, the number and amount of motion varying in different substances, that is, if a substance, say, air, possesses a larger volume than a metal of the same weight, then the atomic energy or motion of the air per unit is much greater. Or a greater amount of force would be required to force an atom of air along any fixed path than would be required to force an atom of the metal.

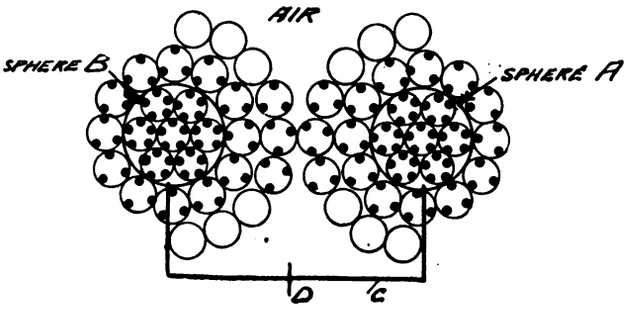


FIG. 1.

Now, it is obvious that if a certain number of primordial atoms possessing motion by revolving round some centre contribute to the atomic value of a substance, that if one or more be added or withdrawn from such an atom that its force or momentum is bound to vary accordingly, and this will naturally affect the other atoms in its neighbourhood. Now, an attempt will be made to depict an electric charge by the preceding principles. Suppose we take again our two spheres, A and B, situated in air, and for simplicity sake we regard each atom of air as being built up of three primordial atoms and each atom of metal of five, revolving in a circle which is shown as the limits of each atom (Fig. 1), and we now cause an etheric force to operate between the spheres by the medium of a wire, C, and an influence machine, D, then if such a force be caused in a direction as shown by the arrow, there will be a tendency for one or more primordial atoms to leave sphere A and move into sphere B; and Fig. 2 depicts a condition when

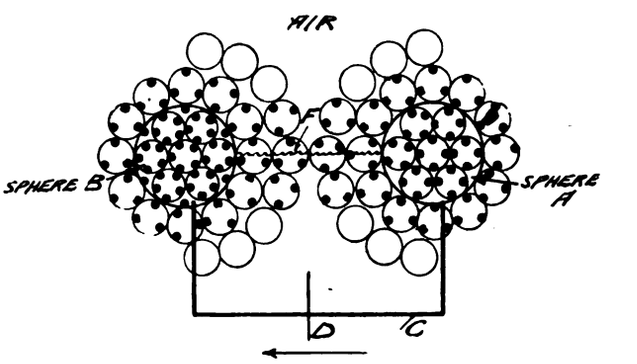

FIG. 2.

an etheric force of sufficient strength is being created as to cause each atom in B to possess one more primordial atom than in A. Now, it is clear that if the atoms in the spheres and the air were in equilibrium before the etheric force was applied that they cannot be now, since the energy possessed by the atoms forming the air resist their passages from whence they were subtracted from sphere A. Since the atoms in sphere B resist the intrusion of the primordial atoms from A caused by the etheric force, and since the air resists their passage again to sphere A, there must obviously be a stress in the air surrounding the sphere and between the spheres, positive round one and negative round the other, and is the most intense along a line F; and there will be a constant tendency on the part of this stress to force these primordial atoms across this space F,

Digitized by Google

and the greater the etheric force applied the greater will be the number of primordial atoms in B (and the less in A), and the greater will be the stress in the air and along the line, F, until such times as the atomic energies possessed by the air of resisting the passage of the primordial atoms across the space, F, to sphere, A, is overcome by the stress, whence an electric spark, and a resulting endeavour to restore equilibrium.

Now, the wire connected in circuit with the spheres, and which was the medium by which they were charged, obviously has some of the primordial atoms disturbed when the organised etheric force is applied, and the number and rate at which they flow will be the current. Provided the metal forming the conductor is more or less homogeneous—which, of course, determines that its atomic properties are fairly uniform—then an organised force in a given direction must cause an organised movement of primordial atoms in a given direction. Fig. 3A depicts a conductor, each atom

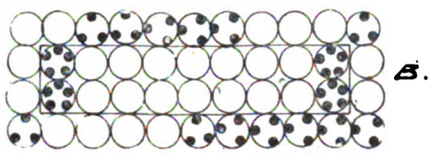

FIG. 3A.

being made up of five primordial atoms in equilibrium with the surrounding medium—air. Fig. 3B depicts the same conductor subjected to an organised etheric force in a direction shown by the arrow at some point A which causes from the moment it is applied one or more primordial atoms to leave each of the atoms and move in the same direction, so that there will be an excess of these primordial atoms at one end, B, and a deficiency at the other end, C. Now, just as the atoms in the sphere B (Fig. 2) resisted the intrusion of primordial atoms, so do the atoms at the end B of this conductor, and so we have a positive stress on the air to the right of A to B and a negative stress to the left of A to C. If we substituted for the air a much better conductor than the

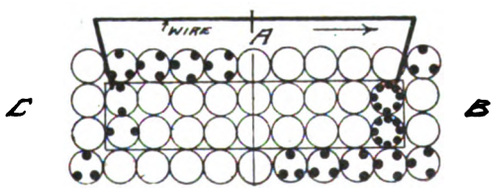

FIG. 3B.

air—say a copper wire—between the points B and C, we would evidently relieve the stress on the air, and these primordial atoms would instantly flow through it from B to C, because the atomic resistance to the transference of primordial atoms is much less in the copper than in the air. We see, then, that a conductor cannot have a charge unless we create an etheric force which causes the flow of primordial atoms, which is current, and when surrounded by a medium (air) we will have resulting a positive stress at one end and a negative stress at the other; but this organised stress is entirely due to the resistance offered by the atoms to the organised intrusion of those primordial atoms forming the current, combined with the resistance of the air to their passage from whence they started. If a number of spheres of some hard substance be placed in a cylinder of some flexible material, and a uniform pressure or stress applied to each one, from the moment this stress was applied there would be a gradual organised movement of the spheres until the stress applied equalled the stress in the cylinder, and is analogous to a uniform etheric stress causing an organised flow of primordial atoms, until the etheric stress applied equalled the etheric stress in the surrounding medium—air. Therefore the flow of current is independent, as regards its organisation, of the resultant stress on the surrounding medium, and the necessity that because this stress is manifested on the outside of a conductor it should flow only on the outside.—JAMES W. TUNSTALL.

Answer to No. 829 (*awarded* 7*s.* 6*d.*).—The latest theories of electricity regard electrical disturbances as elastic reactions in the ether. The exact nature of the ether is at present only a matter of conjecture, but for our purpose we may regard it as an elastic, jelly-like substance, containing imprisoned in numerous cavities and interstices an incompressible fluid—electricity. The above description is only an analogy, for bodies can move through ether, and electricity is not necessarily a fluid, although it obeys fluid laws. Charging a conductor with static electricity corresponds to pumping some of this fluid from one cavity to another. Evidently, since the walls of the cavities are elastic, such a transference is quite feasible. The magnitude of the charge corresponds to the change in quantity of the fluid, and a moment's consideration will show that the increase or decrease in the amount of fluid present resides at the surface of the cavity. This explains why charges of statical electricity reside at the surface of the conductor.

Now, consider the case of a conductor carrying current. The conductor we regard as a hole through the jelly into which the entangled fluid in the neighbourhood soaks. Once in the hole it can respond to the difference of pressure imposed by the generator, and hence flows along the duct. Since the fluid (electricity) will continue to soak in until the hole is completely filled, it is evident that the whole area of the canal or duct will now be utilised. From this it will be seen that the complete section of the conductor is in use when carrying a current. The resistance of the conductor corresponds to a sponge-like path instead of a clear hole.

The following example will, perhaps, make the application of this theory clearer: In the case of a long cable, some time is taken to transmit signals by electricity, due to the capacity of the cable. This may be explained as follows: the electric fluid soaking in from the ether fills the duct, and then, owing to the elasticity of the sides of the path, fluid continues to flow in, distending the sides slightly. Until this stretching is complete the difference of pressure does not come into play, hence the time required for the transmission of the electricity. The distension of the sides of the duct is, as explained above, a charge of statical electricity.—T. J. M.

Answer to No. 829 (*awarded* 5*s.*).—Cannot these two apparently opposed facts be explained in terms of the fundamental and commonly accepted principles of electric action—viz: (1) A conductor is a body which yields (electrically) to electric pressure—*i e*, if a potential difference is originated between any two points in it, the pressure is immediately transmitted in *every* direction until it equalises itself, the action in this respect being exactly analogous to that of ordinary fluid pressure. A conductor is an (electrically) *yieldable* body. (2) A dielectric is one which does not yield (electrically) to electric pressure: consequently potential differences can be maintained from point to point in it. It is an (electrically) yieldable body.

Suppose now that a charge of electricity is introduced at some point within a solid conductor, thereby originating a rise of potential at the point. In accordance with (1) this pressure will be transmitted in *every* direction through the substance of the conductor until equilibrium is attained—*i e*, the whole cross-section of the conductor will be utilised in the process (passage of current). In the next place, this transmission of pressure will travel outwards until it reaches a non-yieldable material—the surface of a dielectric, *e g.*, air.

The pressure within the conductor will now be higher than it originally was, but being everywhere the same there will be no electric *force* within it, and hence no free charge. But immediately we pass from the conductor we step into a region where the electric pressure falls off from point to point. Now it is only through this *difference* of pressure that the electric force manifests itself, hence when equilibrium is once attained (a static charge produced), it is observable only in and on the boundary of the dielectric—*i e.*, on the surface of the conductor.—G. B.

[Other replies to Question No. 829 will be given in our next issue.—ED. *E. E.*]

Supplement to "The Electrical Engineer,"
DECEMBER 29, 1905.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

ANSWERS.

Question No. 829.—When a conductor is charged with electricity, the whole charge resides on the surface of the conductor; when, however, the conductor is carrying a current, the whole cross-section of the material is in use. How can these two commonly accepted facts be reconciled?

Answer to No. 829 (*awarded 7s. 6d.*).—We may very conveniently divide the study of electricity into four distinct portions. In the first portion we consider electricity at rest, or static electricity, in which we study the stresses and strains and other allied phenomena produced in the dielectric which is surrounding a charged body. In the second part we consider electricity in locomotion—*i.e.*, translation as opposed to rotation or oscillation. In this branch of the subject we study the phenomena set up in metallic conductors, in electrolytes, and in dielectric media by the passage of electricity through them. In the third branch we discuss electricity in rotation, whirling, or vortex motion, and stresses and strain produced by these motions. This branch is commonly called magnetism. And in the fourth and last portion we consider electricity in vibration, commonly called light. It will thus be seen that the phenomena mentioned in the query belong to two different branches of the subject, and, therefore, there is some *a priori* reason why the effects noted should be different, for, considering the hydraulic analogy, there is a considerable difference between the laws relating to water in motion compared with those relating to water at rest.

In order to understand why in one case the electricity appears to reside entirely on the surface of the conductor, while in the other it appears to spread over the whole area, we must obtain some sort of theory as to the nature of electricity and what constitutes a static charge and what constitutes an electric current. Fluid theories were put forward during the last century, but a few years ago there was a reaction against them, and a tendency to deny the material nature of electricity and assert its position as a form of energy was prevalent. No doubt there was some excuse for this idea, owing to possible analogies to sound, heat, light, etc. Whatever electricity may prove to be (possibly some form of matter), one thing is certain, and that is, it is *not* a form of energy. Now, this statement must not be misunderstood, for it is quite true that electricity under pressure or in motion represents energy, but the same thing applies to water, and no one would call water a form of energy, although, no doubt, it does contain considerable quantities of energy associated, and with its atoms are material particles.

Again, another argument which points toward a material conception of electricity is that electricity is never created or destroyed, but simply moved from one place to another, or strained, like matter. It is a matter of common knowledge that it is impossible to obtain a positive charge without generating an equal negative charge, which is equivalent to saying that the total algebraic quantity of electricity produced is equal to zero, or that electricity is merely shifted from one body to another. We thus see that electricity is comparable to matter, and, indeed, we may go a little further, and show that it is comparable with a perfectly incompressible fluid—that is to say, it follows the same laws. This is demonstrated by two classical experiments, one being the experimental proof that the charge resides on the surface by means of the sphere with removable outer coating usually attributed to Biot, and the other Faraday's insulated metallic room experiment. The first of these experiments has been carefully repeated by many notable experimenters using a delicate Kelvin electrometer instead of the rough gold-leaf electroscope, and they have obtained conclusive evidence that the charge, whatever it may be, resides on the outer or may be just outside the surface in the dielectric. That it only extends to less than the depth of a few molecules is shown by an experiment due to Prof. Boys, who found that one soap bubble was entirely screened by another bubble blown outside it.

If an attempt is made to introduce some electricity inside a conductor, this disappears, and an equal quantity appears outside. Compare this phenomenon to its hydraulic analogue, and the resemblance of electricity to an all permeating incompressible fluid becomes apparent. If by suitable means a quantity of water is introduced into a closed vessel already full of water, then, assuming water to be incompressible (which it is not), an equal quantity of water will be forced through the bounding walls to make room for that which is introduced. The water introduced loses it individuality, while that forced out is distinct from the rest. Work is done in both cases; in the electrical case this energy is converted into strain energy in the surrounding dielectric, and is due to electricity being under pressure, and constitutes what we call an electrostatic charge. In Faraday's experiment he built an insulated metallic room large enough for him to get inside, and in there he performed all sorts of electrical experiments, drawing long sparks from electrical machines, etc., without permanently affecting a delicate electroscope attached to the room outside. We may again compare them with an hydraulic experiment; however fast we may work a pump entirely enclosed in a closed vessel full of water, no water would be forced in or out. We thus see that the theory that electricity is something resembling matter in the form of an incompressible fluid which permeates all space and entirely fills it, explains why the charge appears to reside at the surface.

Now, proceeding to the second case. Here we have electricity in motion, and the question naturally arises, How is it transmitted? Does it pass through or between the molecules, or is it handed on from molecule to molecule? The latter explanation seems the most likely, for, according to the kinetic theory of matter, the molecules in a solid have a vibratory movement about a fixed point. If, then, one molecule receives a charge, it will in a very short time share it with its neighbours, owing to collisions between them, while those receiving the charges will part with them in a similar manner. If the first molecule receives a second charge immediately after losing the first, it will pass this on in the same manner, and an electric current will result. Now, remembering that what we call a charge of electricity is the strain produced in the dielectric produced by electricity under pressure, the current is then merely the setting up and almost simultaneous breaking down of the strain in the dielectric surrounding the molecule. As all the molecules bar those very near the surface are similarly situated with regard to those in its immediate neighbourhood, there is every reason to suppose that they will all share about equally in the charging and discharging process,

Digitized by Google

and, therefore, the whole area will be requisitioned to transmit the electricity. For developments and a full discussion of the difficulties surrounding this theory which identifies electricity with the ether, the reader should consult Sir Oliver Lodge's book on "Recent Views on Electricity."—B.Sc.

Answer to No. 829 (*awarded* 5*s.*).—The chief points to be remembered when comparing an electrostatic charge with current flowing through the section of a conductor are briefly as follows:

1. Since the static charge is electricity *at rest*, the *material* of the charged body does not affect the behaviour of the charge. If a sphere is to be charged, it makes no difference whether it be of copper, iron, or wood covered with tinfoil. The charge resides on the outside by reason of the influence of the *surrounding dielectric*, which is the regulating factor. The potentials met with in electrostatic work are usually incomparably higher than those in ordinary direct or alternating current practice—*e.g.*, a ball of metal beaten with fur may readily obtain a potential of 50,000 volts—a good plate machine 200,000. Of course, the current values are correspondingly minute, but it will be clear that these pressures set up a strain between the charged surface and the nearest body of lower potential, which depends on the medium between the two bodies. The dielectric serves as insulator, but also transmits the strain, which causes a discharge if sufficiently increased.

2. Considering the conductor carrying a current, we know that the specific resistance of the conductor (the nature of the material) is an all-important factor in determining the current value. The potential employed, however, is probably so low compared with that of the static charge that the strain on the dielectric becomes negligible, whilst substances which act as conductors in static work, like wood, become efficient insulators. If a direct E.M.F. be applied, a flow of current takes place through the conductor from positive to negative poles. The resistance of the conductor determines the current strength, and the current is distributed throughout the cross-section of the conductor with equal density in every part. In the case of an alternating circuit there is an *unequal* distribution in the conductor, the density increasing outwardly from the centre of a circular conductor; but this is due to the effect of mutual inductance in the conductor, and not to the surrounding dielectric. A static discharge is, of course, a minute current, but so infinitesimal that the idea of current density at the point of discharge is not worth consideration. —A. M. L.

Question No. 830.—A dynamo is to supply lamps and also charge a secondary 50-volt battery of six cells. When dynamo is not working, the battery will feed the lamps. Describe a "fool-proof" arrangement so that, whether dynamo or battery feeds the lamps, a V.M. and an A.M. should always remain in circuit. Also arrange that three or more cells may be thrown into the circuit as required.

Answer to No. 830 (*awarded* 7*s.* 6*d.*).—Before answering this question I think it would be advisable to point out the mistake in the second line—viz., "a secondary 50-volt battery of *six* cells." This is certainly meant for *twenty-six* cells, which is the number generally used on a 50-volt installation. Fig. 1 shows the connections for a small private generating installation. Here Dy is the main dynamo, F its field coil. D P S and D P F are double-pole switch and double-pole fuse respectively. B B represents the battery. Those at the left-hand end are connected to multiple-way charge and discharge switches, C and D, the former being joined up with one pole of the dynamo, and the latter with one of the mains running to the lamps, L L. A is an ammeter permanently connected on one side with the dynamo, and on the other with the service main and through a two-way switch, T S, with the right-hand end of the battery. When the switch is on the bottom contact, A indicates the current from the dynamo, while if it be on the top contact, A shows the current passing to the lamps. The "two-ways" or "contacts" should be placed close together, so that the battery circuit shall not be broken when moving the contact finger from one to the other. The voltmeter, V, is permanently connected to the ammeter end of the circuit, and through a two-way switch with the charge and discharge side of the circuit. In the first case it indicates the voltage of the dynamo, and in the second the voltage of the battery. As one or more of the cells on the left-hand side may not be used during discharge, they will not require so much charging as the others; therefore, they can be cut out of circuit by the switch, C. A′ is an automatic switch, which closes the circuit when the dynamo

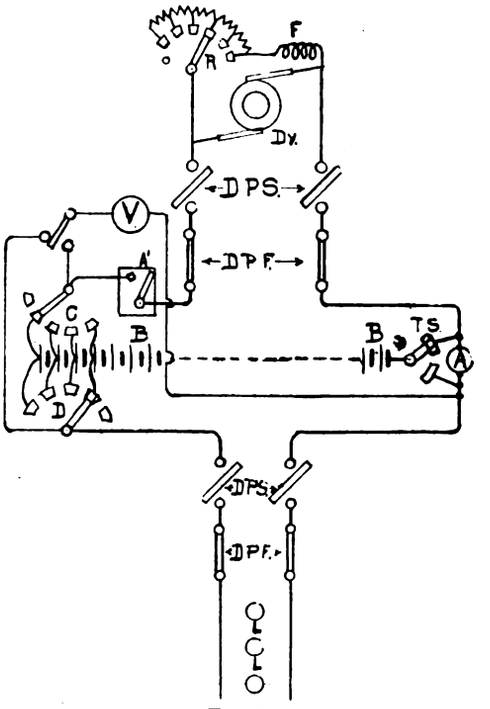

Fig. 1.

voltage rises sufficiently above that of the battery, and breaks it if from any cause the generator voltage should fall below that of the battery. The two switches, C and D, should be special battery regulating switches, so as to prevent short-circuiting the cell between the two contacts when moving the contact arm.

Fig. 2 shows a form of switch that may be used. Fixed on the side of the main contact, but insulated therefrom, is a small auxiliary contact, A, electrically connected to the main contact by a short wire, W, of high resistance. The distance between the contacts, C C, is such that in moving the switch arm from one to the other the circuit is never actually broken, the cell between the two adjacent contacts

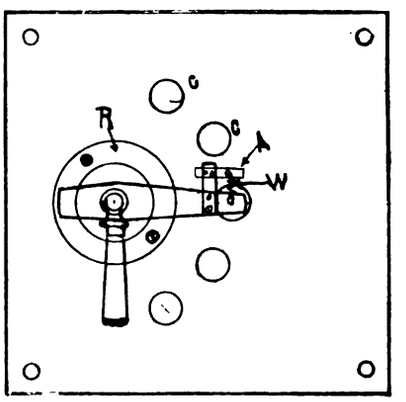

Fig. 2.

being momentarily shorted through the wire, W. The main contact must also be small enough so as not to bridge two adjacent contacts.—P. S.

Answer to No. 830 (*awarded* 7*s.* 6*d.*).—It is an easy matter to arrange for an ammeter to be always in circuit with the lamps and a voltmeter to be across the terminals of the circuit. The necessary arrangement is shown in Fig. 1, and is quite "fool-proof" as far as it goes (full lines only) As, however, the installation is evidently to be in unskilled hands a few further precautions are necessary, and in any case it is essential to the efficient working of the battery that the charging and discharging

Digitized by Google

currents should be known. Fig. 2 is the diagram of connections for a board which would be suitable for the purpose; it is not arranged for battery and dynamo to run in parallel on the load, but should this be required at any time there will be no difficulty in providing for it without any radical alterations, as explained below. The six sets of cells, which consist of 28 cells in series, each forming a

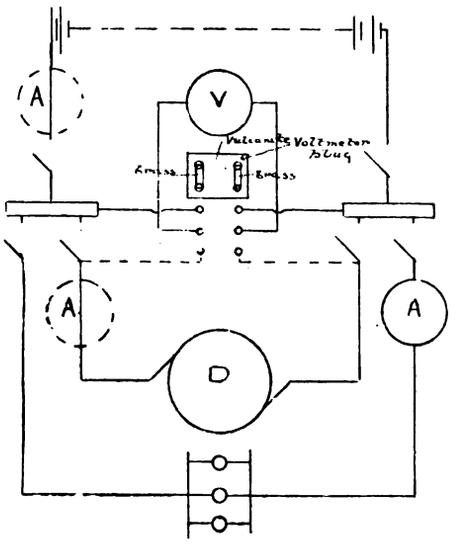

FIG. 1.

separate battery, are connected through switch fuses to a common 'bus bar at the + end; at the − end four cells are connected in parallel to a regulating switch, having an advance arm insulated from the main arm at the lower end, and connected to it at the top end by a low resistance. This arrangement prevents the cells being short-circuited by the arm when passing from one contact to another.

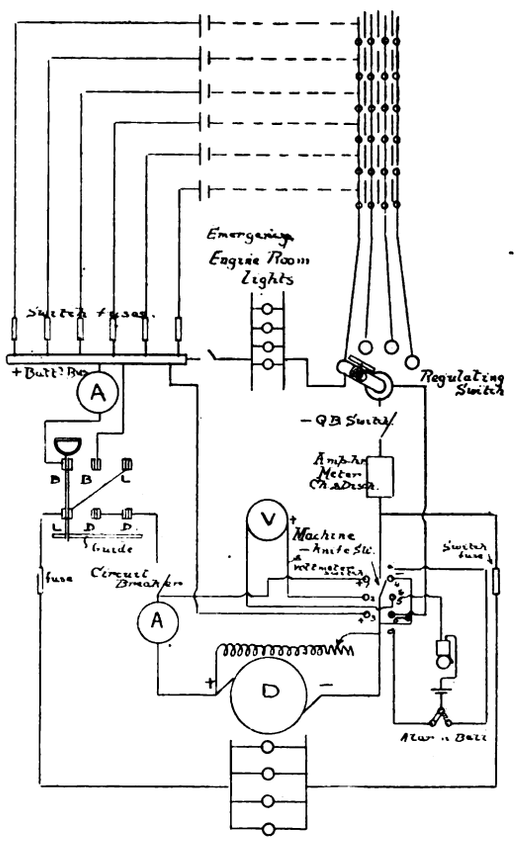

FIG. 2.

It would, of course, be possible to connect the regulating cells in such a manner that the − end of any battery could be cut off from the board, but that would be an expensive and complicated arrangement. The best connections may be made by means of four copper rods running to the regulating switch contacts, with T's to the regulating cells, as indicated in the diagram. The T's should be capable of easy removal when required. All the bare copper in battery-room should be protected by a coat of acid-proof paint. In series with the regulating switch and − battery switch is an ampere-hour charge and discharge meter, which is a very important adjunct to the battery. The switch on the left consists of three sets of contacts with only one blade, which may be used in any of the three sets. The arrangement of ammeters shown ensures that the current is always indicated on one ammeter only, and in conjunction with the three-way switch, which should be marked as shown, it is extremely easy to follow whatever is going on. The dynamo is protected by means of a maximum and reverse current circuit breaker on one pole and a knife switch on the other. This knife switch is shown in Fig. 3, and has two sets of auxiliary contacts which operate the voltmeter, so that when machine is not running the battery volts are indicated, and when the machine is about to be switched in the machine volts are indicated. The voltmeter connections can be easily followed in Fig. 2, and it will be seen that a bell is also connected up. This bell acts as a reminder to look after the machine volts when running up, and continues ringing until switch is moved over. When machine is switched out, the bell will again ring until switched over to the other circuit. This ensures that the bell will always ring before machine is switched in.

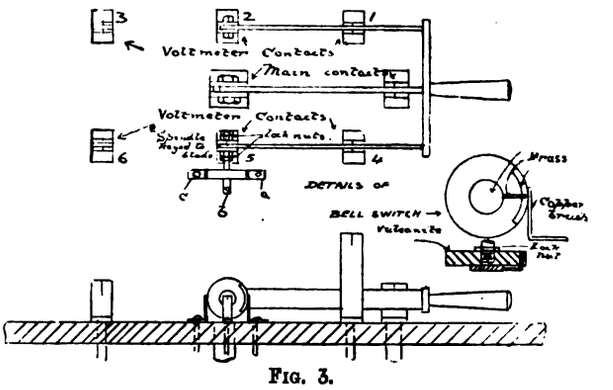

FIG. 3.

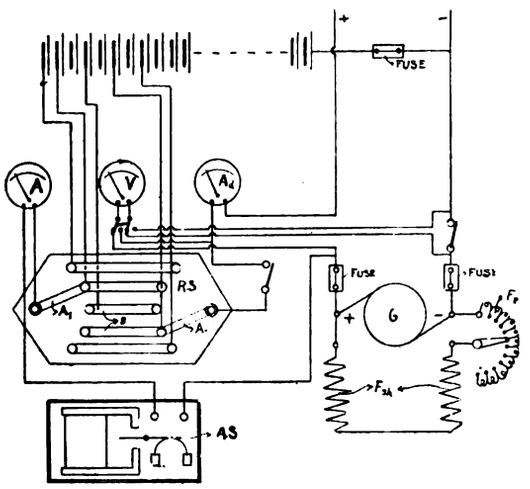
Now, as to operating this board. Any number of batteries may be used, but it would be advisable to use the same number always, keeping those out of use fully charged up and disconnected both ends. The currents flowing in each battery circuit ought to be known, and for this purpose shunts may be fixed in each circuit to a system of plugs leading to a common ammeter. To avoid any chance of confusion, this ammeter should be distinctly marked. When switching on the dynamo to battery or lamps, care must be taken that machine voltage is equal to battery voltage or voltage necessary for lamps, as the case may be, or a sudden rush of current or burst lamps may result. Similar precautions should be taken before switching battery on to lights. No provision is made for changing over from dynamo to battery without extinguishing lights, as this means additional complications with both ammeter and voltmeter switches, which would render the arrangement less fool-proof. Probably, however, the battery will be charged up and changed over before dark, and in any case the inconvenience is momentary. If, however, it is necessary to run battery and dynamo in parallel on the load in an emergency, this can be effected by connecting the terminals, D L, with a plug, the switch being in position shown connecting B L Should it be necessary to run battery and dynamo in parallel as a rule, and also to change over without extinguishing lights, the writer would strongly advocate a board built upon the principle of Fig. 1, including dotted lines, and the engagement of an intelligent man to look after it. The probability is that he would be a good investment in any case.—D. M H. 97.

Answer to No. 830 (*awarded* 5*s*)—The following is a description of an installation which I have no doubt will entirely suit "K C. N.'s" requirements. I have installed systems similar to this and have found them in all cases to be reliable and to give complete satisfaction, and I may here state that they have usually been left in the hands of an unskilled workman, thus showing the extent to which

Digitized by Google

they are "fool-proof." The general lay out of the system will be easily followed from the diagram of connections. G is a shunt-wound generator capable of generating from 50 to 70 volts and the required amperage. If the generator is required to supply sufficient current for the whole of the lights at one time, which is usually the case, then the output will have to be sufficient for this purpose, but if the battery is discharged during the "peak of the load," a dynamo of less output may be installed and the battery may be charged during the hours of practically no discharge. The reason why the generator ought to give an E.M.F. of 75 volts is this: when the battery is fully charged, the E.M.F. of each cell will rise to approximately 2·7 volts, depending upon the rate of charge, therefore $26 \times 2{\cdot}7 = 70$ volts, which is the E.M.F. required to overcome the back E.M.F. of the battery. F_{sh} is the shunt field and F_r the field resistance in series with the shunt field. If the speed of the dynamo can be altered by means of a sensitive governor on the prime mover, the field resistance may be discarded, but it is advisable in most cases to run the dynamo at a constant speed and vary the voltage by means of the field resistance A S is a Neville's patent automatic switch. R S is a regulating switch. It consists of brass bars, B, suitably mounted on a marble or slate base, and to which are connected cables leading from certain cells in the battery. Movable arms, A A_1, can be so adjusted as to make contact



with any one bar, and, therefore, with any particular cell in the battery with which these bars are connected. The function of this switch is to be able to supply the lamps with current at a proper voltage at the same time that the battery is being charged, or to proportion the discharge current between the dynamo and the battery by means of the movable arms, A and A_1. As I stated before, the E.M.F. of each cell when fully charged will be about 2·7 volts, therefore the number of cells required in the battery to give 50 volts to the lamps, assuming them to be 50-volt lamps, will be $50 \div 2{\cdot}7 = 19$ cells. The bottom bar of the regulating switch will, therefore, have to be connected to the nineteenth cell in the battery, and the discharge movable arm, A, adjusted so as to make contact with this bottom bar. When the battery is taken off charge, the voltage will gradually decrease. It will be necessary to increase it. The point to be now considered is how many cells are to be put in. To obtain an almost imperceptible increase of light from the lamps, due to the increase of voltage when cells are put in circuit, connections ought to be made to each of the remaining cells, but this would require an elaborate and expensive regulating switch in proportion to the size of the installation. Connections to cells 19, 21, 23, 25, 26 would be very suitable in this case. It is well known that the top cells or those at the positive end of a battery always get fully charged before those at the negative end. If these cells were left in circuit they would cause a waste of energy, but by means of the regulating arm, A_1, these cells when fully charged can be cut out of circuit. The discharge ammeter, Ad, is permanently connected in circuit, as indicated in the diagram. It is also advisable to have an ammeter in the machine circuit and also a voltmeter, so as to be able to see exactly what load is on the machine. Only one voltmeter is necessary for indicating the dynamo and line voltage if a throw-over switch is provided and connected according to the diagram. The method of placing the machine on load is as follows: The dynamo is run up to speed and the negative machine switch is closed. If the voltage of the machine is high enough to overcome the battery E.M.F., the automatic switch will close the circuit. If not, the voltage may be increased, either by increasing the speed or decreasing the field resistance, until the switch automatically closes. It will be seen that if from any cause the driving power fails, the automatic switch will automatically break the armature circuit, and thus prevent any possible damage to the dynamo.

A less elaborate and less expensive switch may be substituted for this automatic switch, but a switch working automatically I strongly advise to be put in the machine circuit, as it almost totally prevents any damage being done to the dynamo. Of course, fuses ought also to be put in the circuits where required.

There is one point in the running of an installation similar to this which I wish to particularly emphasise, and that is to run the generator during the "peak of the load." Not only does this give a higher efficiency (units consumed by lights ÷ units generated), but greatly reduces the cost of maintenance and renewal of the battery, which is no small item in a private installation. Where the driving power is water, and obtained at little or no cost, the question of efficiency need scarcely be considered.

There is an alternative arrangement, in which the regulating cells are placed in the centre or some other convenient point of the battery. This arrangement necessitates either the disconnection of the lamps from the battery and machine when charging, or the addition of a "booster" to the installation previously described. In a very large installation, say of 250 cells, this arrangement is perhaps the better, but in the case of a comparatively small installation of 26 cells is impracticable, and need not be further considered.—JOHN J. RICHARDSON.

Electrical Refuse-Loading Plant.—In Germany, municipalities are on guard to prevent anything taking place within the city limits which will in any way discomfort the inhabitants or lead to insanitary conditions, and in Berlin, to cite a recent example, the company dealing with the conveyance of refuse from houses are obliged to provide special means of avoiding the production of dust in connection with the loading. Accordingly loading stations were erected in different parts of the city, and that of the Silesian Railway Company is described in the *Western Electrician*. A horse-drawn wagon enters a hoisting cage which is suspended from wire ropes, the doors of the latter being locked and the cage lifted by means of electric motors and conveyed laterally above a large chamber, where it is stopped. Next, a lever mechanism is actuated, the traps open, and the whole of the refuse contained in the bin drops into a railroad car situated underneath. The chamber is kept locked on all sides during the operation, and no dust is allowed to escape. The discharge requires very few minutes, after which the hoisting wagon will return the same way, the empty wagon being removed while the second cage is raised on the other side of the chamber. After having thus filled the railroad car with the refuse, it is safely covered, and conveyed by means of electrically-driven capstans to be disposed of. The lifting of a hoisting wagon, each of which with a loaded wagon, horses, and driver weighs two tons, is effected by two hoists driven by a 15-h.p. motor, while two 5-h.p. motors are set apart to effect the transverse motion. The driver's cabin, containing all the switching, controlling, and starting apparatus required for the service, and whence a good view and ready control are obtained of the whole plant, is located laterally on the pillar of the hoist. The energy required to feed the motors is supplied from the mains of the Berlin Electricity Works.

Contract and Miscellaneous Advertisements should reach this Office by First Post on Thursday Morning. For rates apply to the Manager, 139-140, Salisbury Court, Fleet Street, London, E.C.

CONTRACTS.

BOROUGH OF BARROW-IN-FURNESS.

ELECTRICITY DEPARTMENT.

CONTRACT No. 16.

The CORPORATION are prepared to receive TENDERS for the SUPPLY and ERECTION of—

SECTION A.—One 500-kilowatt Combined Steam-Engine and Generator.
" B.—One Balancer Booster.
" C.—Switchboard Panels and Connections for Generator and Booster.
" D.—One Water-Tube Boiler with Superheater.
" E.—One Mechanical Stoker.
" F.—Steam and Exhaust Pipes, Valves, &c.
" G.—One Economiser.
" H.—Ironwork.
" I.—One 15-ton Travelling Crane.
" J.—One Cooling Tower.

Complete Specifications may be obtained after the 23rd inst. from Mr. H. R. Burnett, Electricity Works, Barrow-in-Furness, on payment of One Guinea, which will be returned upon receipt of a bona fide Tender.

Specifications and Drawings may also be seen upon application at the Electricity Works.

Sealed Tenders, endorsed "Contract No. 16—Section —," to be addressed to "The Chairman, Electricity Committee," and delivered at my office not later than 12 noon on MONDAY, November 13th, 1905.

The Corporation do not bind themselves to accept the lowest or any Tender.

By order,
C. F. PRESTON,
Town Clerk.

Town Hall, Barrow-in-Furness.

MANCHESTER CORPORATION TRAMWAYS

The TRAMWAYS COMMITTEE of the Manchester Corporation are prepared to receive TENDERS for the SUPPLY of—

(a) TRAMCAR TRUCKS
(b) ELECTRICAL EQUIPMENTS for CARS.

Specifications and Forms of Tender may be obtained on application to Mr. J. M. McElroy, General Manager, Tramways Department, 55, Piccadilly, Manchester.

Tenders are to be addressed to the Chairman of the Tramways Committee, 55, Piccadilly, Manchester, and must be received not later than 1 p.m. on SATURDAY, 11th November, 1905.

The Committee do not bind themselves to accept the lowest or any Tender,

WM. HENRY TALBOT,
Town Clerk.

Town Hall, Manchester, 27th October, 1905.

CORPORATION OF BRISTOL.

TENDERS FOR THREE-PHASE CABLES.

The ELECTRICAL COMMITTEE require TENDERS for E.H.P. and L.T. THREE-PHASE CABLES.

Particulars to be obtained from the undersigned on payment of Two Guineas, which will be returned on receipt of a bona fide Tender.

The lowest or any Tender not necessarily accepted.

H. FARADAY PROCTOR,
City Electrical Engineer,
Bristol.

Nov. 1st, 1305.

APPOINTMENTS VACANT.

THE UNIVERSITY OF LEEDS.

DEPARTMENT OF ELECTRICAL ENGINEERING.

The COUNCIL of the University invite APPLICATIONS for the appointment of ASSISTANT LECTURER and DEMONSTRATOR in ELECTRICAL ENGINEERING, to be made up to NOVEMBER 18th. Salary, £175 a year.

Further particulars may be obtained from the REGISTRAR.

FOREMAN for Tool-room WANTED for electrical engineering works. Must be an up-to-date man with all-round knowledge of tool-room work; must also be thoroughly acquainted with the latest methods of die making for armature stamping. Good wages and permanent job to right man.—Apply, No. 505, *Electrical Engineer* Office.

WANTED, a competent WIREMAN for Electric Light and Power Plant. Applicant must be also thoroughly accustomed to crane, motor, and controller wiring.—Applications, stating age, experience, and wages required, and enclosing testimonials, to be addressed to Box 23, *Electrical Engineer* Office.

CANVASSER WANTED by a Firm of Electrical Contractors in London.—Experienced men only invited to reply, stating age, experience, and salary required, to Box No. 514, *Electrical Engineer* Office.

AN ELECTRICAL CONTRACTING FIRM require REPRESENTATIVES in the principal centres of Great Britain. Liberal commission.—Box G 33, *Electrical Engineer* Office.

WANTED, First-Class REPRESENTATIVE for South Wales district, for the sale of Direct and Alternating Motors. Apply, Box F Z, *Electrical Engineer* Office.

ENGINEERING SUPPLEMENT.

ELECTRICAL EXHIBITION AT OLYMPIA.

. . . It is to be observed that this competitive war, which in other industries might easily have led to shoddy work, has brought no such result to British electrical engineering. There is no shoddy at Olympia . . . . Rules and specifications . . . . have undoubtedly added to the force of these inherent protective influences; but supporting everything is the array of modern electrical instruments, whose accuracy and scope are at once the safeguard and pride of the electrical profession. Olympia to-day is testifying to a fact which many older industries may observe with advantage—the progress which results from the application of exact methods of defining, testing, and designing the *materiel*. . .

. . . . . .

INSTRUMENTS.

Of new instruments, the most comprehensive exhibit is probably that of Messrs. Everett, Edgcumbe, and Co. (No. 8). Attention may be called to their direct-reading watt-photometer, which, by a single adjustment, measures candle-power, watts, and the efficiency of a glow lamp in watts per candle-power. Their street photometer is designed on the "Flicker" principle. The "inkless" synchronized recorder is likely to be one of the most useful developments in this class of instrument. Friction between the moving paper and the stylus is obviated by supporting the stylus clear of the paper; at recurring short intervals the stylus is tapped into contact and makes a mark by means of an inked ribbon. The principle is somewhat similar to that of the vibrator of a siphon recorder; the vibrations are, however, timed and actuated by an electrically-driven clock. . . . . .

EVERETT, EDGCUMBE & CO., Ld.

HENDON and VICTORIA STREET.

FILES.—About 5cwt. Slightly Imperfect ENGINEER FILES—assorted 5in. to 16in.; assorted flat, hand, half-round, round, and square; assorted bastard, second cut and smooth—to clear very cheap for cash. Particulars on application, MANAGER, Charleston Works, Orange-street, Sheffield.

MOSELEY'S

Rubber Gloves.

"THE CONTRACT JOURNAL,"

PUBLISHED EVERY WEDNESDAY, PRICE 6d.

Offices: 139-140, Salisbury Court, Fleet Street, E.C.

Besides Articles, Notes, &c., discussing questions of interest to all Contractors, this Paper gives each week a List of Contracts of all kinds open to public Tender, and the Prices at which work has been let. The Paper is especially interesting to all Manufacturers; and it appeals to Electrical Contractors in that therein they obtain a clue to almost all the New Buildings being erected for local bodies or firms in which Electric Light or Electric Power is likely to be adopted.

"The Contract Journal" circulates largely among Government Departments, Local Authorities Municipal Authorities, Architects, Engineers, Contractors, &c.

"The Contract Journal" and "The Electrical Engineer" are under the same Editorial management.

All letters other than Editorial should be addressed to Mr. A. Pitman Secretary and Manager, 139-140, Salisbury-court, E.C.
